Arc Lighting.—The earliest means of applying the electrical current to the production of light was discovered in 1810 by Sir Humphry Davy, who found that when the points of two carbon-rods, to which the terminals of a powerful battery were connected, were brought into contact and then drawn a little way apart, the current continued to pass across the gap, forming what is known as the electric arc (fig. 1) is brilliantly luminous. The points of the carbon-rods become highly incandescent, and in addition the space between them is filled by a sort of flame, or cloud of particles of white-hot carbon. As the temperature of the arc is much higher than that of any ordinary flame, its efficiency as a source of

light is exceptionally great, and it is specially rich in highly refrangible (or short wave-length) rays. The carbon-points being exposed to the air gradually burn away, and in addition to this there is a transfer of carbon particles across the arc from the positive to the negative rod, which has the effect of making the positive rod waste about twice as fast as the negative rod. The end of the negative rod becomes somewhat pointed, and a crater-like hollow forms on the end of the positive rod. As the points waste away the arc lengthens, and would presently break and the current would cease to pass if the rods were not pushed nearer together. Should the arc break it can be re-established by bringing the rods again into contact, and again drawing them a little way apart. Arc lamps are devices for holding the carbon-rods, so that they are first brought into contact and drawn apart, to establish or 'strike' the arc, and are then 'fed' together, continuously or at short intervals, to prevent the distance between the points from growing too long.

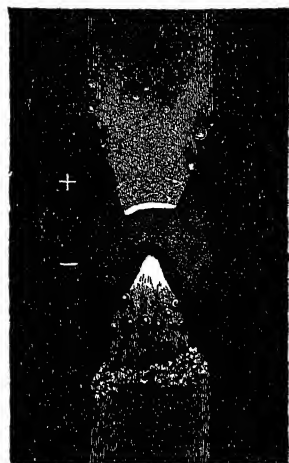

Fig. 1.

It was not until the development of the Dynamo-electric Machine (q. v.) as a means of producing the electric current economically on a large scale that the electric light came to be of commercial importance. Before that, however, various contrivances had been devised for automatically striking the arc and regulating its length. As early as 1847 a lamp was patented by W. E. Staite, in which the carbon-rods were set vertically one over the other, the upper one being held fixed, while the lower rod was fed upwards by the intermittent action of clockwork, which came into gear whenever the current across the arc became reduced below a certain limit of strength through the lengthening of the distance between the carbon-points. Similar devices were proposed by Foucault and others; but the first really successful arc lamp was Serrin's, patented in 1857, which has had its main features reproduced in many later forms. In 1858 a lamp designed by Duboscq was used to show the electric light, for the first time at sea, from the South Foreland Lighthouse, where the current to feed the lamp was generated by the large magneto-electric machine of Holmes; and this experiment was followed a few years later by the permanent establishment of electric lighting there and at Dungeness and other lighthouses. The invention of the self-exciting dynamo in 1867 paved the way for the development of electric lighting on a commercial scale. The Jablotchkoff candle (1876), in which the arc was formed between the ends of a pair of parallel carbon-rods separated by a layer of insulating material which was slowly consumed as the carbon burned down, did good service in accustoming the public to the new illuminant, and the invention of simple and effective arc lamps by Brush and others brought about its wide adoption in 1878-79 for lighting large rooms, streets, and spaces out of doors. In the following year the future of domestic electric lighting was

seemed by the introduction of the incandescent lamp.

The rate at which energy is expended in the electric arc is measured by the product of the current and the electromotive force required to maintain it passing across the gap. If the current be measured in amperes and the electromotive force in volts, their product gives the rate of expenditure of energy in watts, and may be reduced to horse-power by dividing by 746. It is found that the electromotive force between the points is nearly constant whether much or little current is passing, which shows that the opposition to the passage of the electric current across the gap is different in kind from the resistance of an ordinary conductor. However short the arc be, it requires an electromotive force of from 30 to 40 volts to maintain it; when the arc is lengthened the electromotive force necessary to keep up the same current is increased, but not in proportion to the length. It is not found practicable to maintain the arc with less than a certain strength of current. Hence the power consumed in an arc lamp is necessarily considerable, and the lamp can be employed to advantage only where a large amount of light will be serviceable. The ordinary continuous current arc lamps which are most extensively used take from three-quarters to one horse-power, and have an illuminating effect equivalent to something like 1000 candles. It is impossible to speak with any precision of the candle-power of an arc lamp, because its light differs enormously in colour from that of a standard candle. A comparison of the blue rays of the arc with the blue rays of the candle will give a figure nearly three times more favourable to the arc than if the comparison be made between the red rays.

The alternating current lamp is somewhat less efficient, requiring about 1.12 watts per candle. This is because the continual change of polarity keeps both carbons pointed, which results in as much light being thrown upwards as downwards. The temperature attained is also not quite so high, for the hottest point in the arc, instead of remaining stationary, changes its position with each reversal of current. On the other hand, 'choking coils' can be used in place of series regulating resistances required for direct current lamps, which enables the pressure at the terminals to be adjusted to the proper amount with a smaller expenditure of energy.

In so-called enclosed arc lamps a smaller globe inside the usual one practically excludes fresh air from access to the incandescent carbons, with the result that these burn away at a much slower rate, and remain flat-ended instead of becoming conical. Such arcs are longer, and give a more uniform illumination. The pressure required is also greater, being some 80 volts, which enables a single lamp to be connected in series with only a small steady resistance across 100 volt mains. The efficiency of an enclosed arc is, however, markedly inferior to that of 'open' arcs, the power consumption being about 1.5 watts per candle with continuous current, and almost 3 watts per candle when the current is alternating.

In 1899 Bremer produced his flaming arc lamp, which is easily recognisable by its yellow tint and absence of shadow. The yellow tint is obtained by adding certain metallic salts during the manufacture of the carbons. The entire absence of shadow is because there is no lower carbon to obstruct the light. Both carbons are fed downwards through tubes inclined at a small angle on either side of the vertical, and meet in an inverted cup termed the 'economiser,' which shields the arc from draughts, limits the supply of oxygen, and acts as a reflector. A magnetic field is made to act upon the arc in

such a way as to blow it out into the shape of a fan, the electro-magnetic effect on the arc being similar to what would be experienced by a conductor carrying current. The efficiency of these lamps is very high, being of the order of 6 candles per watt.

Early in 1903 the Cooper-Hewitt mercury vapour arc lamp made its appearance. In its simplest form it consists of a sealed glass tube about 1 inch in diameter and 3 or 4 feet long, according to the voltage. The tube is highly exhausted, and contains little else than mercury vapour. The current is led in at opposite ends of the tube through suitable electrodes. To start the arc, the tube is tilted in such a way as to cause a fine thread of mercury to flow from one end to the other. The light is well diffused along the whole length of the tube, but is of an unpleasant greenish tinge.

A peculiar property of the mercury arc is that it will not persist unless the cathode or negative electrode is a pool of mercury, a portion of which is kept hot or 'alive.' This is because the mercury cathode has to supply a continuous stream of mercury vapour which carries the discharge by becoming ionised. The anode or positive electrode, however, need not consist of a mercury pool. It usually takes the form of an iron or carbon terminal connected to the leading-in wire, and so arranged that it is prevented from getting hot.

To obtain a steady discharge through a lamp constructed on this plan it is evidently necessary to supply it with direct current, the mercury electrode being connected to the negative pole.

If an alternating current is used, current can only pass during that phase of the current in which the mercury pool is the negative electrode and the iron or carbon the positive electrode. This unilateral conductivity or 'valve action' dependent upon the different nature and temperature of the electrodes has made it possible to develop the *mercury arc rectifier*, whereby a steady direct current can be derived from a three-phase alternating source of supply.

In the larger sizes of mercury arc rectifier the glass bulb is replaced by a steel container suitably insulated.

The efficiency of the mercury rectifier is high, the chief loss being a constant drop of about 15 volts in the arc. Moreover, the efficiency is well maintained at light loads. As the pressure drop is constant, the efficiency of the mercury rectifier shows to advantage when the d.c. voltage is high, such as 1500 volts, now widely used in France for traction purposes.

Incandescent Lighting.—In early attempts to produce light by the incandescence of a heated conductor, wire of platinum and of other refractory metals was employed; but these become melted or disintegrated at too low a temperature to let them serve as efficient sources of light. Carbon rods also had been used, but the matter was not brought to a practical issue till 1879, when Mr Edison (and, almost at the same time, Mr Swan) made lamps in which the incandescent conductor was a fine thread or filament of carbon, enclosed in a glass globe, from which the air was exhausted as completely as possible. The filament was originally formed by carbonising a thread of paper, cotton, bamboo, or other vegetable fibre; it is now more usually made by forcing a semi-fluid preparation of cellulose through a die, bending and drying the thread, and heating it to a very high temperature, surrounded with plumbago, in a crucible. The ends of the filament are attached to short conducting wires of platinum, which are sealed into the globe. By making the filament longer or shorter, thinner or thicker, the lamp is adapted to be used with more or less electromotive force, and to give more

or less light. The lamp has a limited life, for the filament undergoes a slow process of disintegration, which finally breaks it. As in the case of an arc lamp, the power consumed is measured by the product of the current and the electromotive force or difference of potential between the terminals. In ordinary use incandescent lamps with carbon filaments consume from 3 to 4 watts per candle of light, and last for some 1000 hours. One may force them to a higher efficiency by increasing the electromotive force, so that the temperature of the filament is further raised, and the light is much increased with the expenditure of but little additional power. But this shortens the life of the lamp, and tends also to make a deposit of carbon particles form on the inside of the glass.

A new departure in incandescent lighting was made in 1897 when Professor Nernst introduced the lamp which bears his name. As long ago as 1877 Jablochhoff had discovered that the oxides of certain rare earths, which are non-conductors when cold, become conductors when raised to a high temperature. The filament of the Nernst lamp is composed of oxides of zirconium, thorium, and cerium, which behave in this manner. Owing to its incombustible nature, there is no need to enclose the filament in a vacuum. To start the lamp burning, the filament must be heated from some outside source, such as a Bunsen flame or electrically heated platinum resistance coil, until its temperature is raised to some 700° C. Current then begins to flow, which by its heating effect further raises the temperature of the filament, thereby improving its conductivity and allowing more current to pass. At this stage the external source of heat can be withdrawn, while the filament, heated more and more by the increasing current, quickly attains a dazzling brightness. As the temperature is very high, about 2500° C., a high efficiency is to be expected, and tests have shown that the power consumption may be as low as 2 watts per candle. As the conductivity of the filament increases very rapidly with the temperature, it is found necessary to put a steady resistance of fine iron wire in series. This resistance is designed to work at a red heat, and in this way a fairly constant total resistance is maintained.

The complications necessary to provide a heater which shall automatically disconnect itself when the lamp starts burning makes the lamp expensive and liable to get out of order, added to which the useful life of the filament is seldom more than 500 hours. These drawbacks have seriously hindered the commercial success of the lamp, and the introduction of metallic filament lamps may be said to have led to its being almost entirely superseded.

It had long been known that certain refractory metals could withstand higher temperatures even than carbon, but no way had been found of working these metals into fine wires suitable for lamp filaments. In 1903, however, means were devised for drawing fine wires of tantalum. Lamps employing filaments obtained in this way have a consumption of only 2 watts per candle, and give an illumination approaching daylight in colour value. Almost at the same time a method was introduced for squirting filaments of osmium, the most refractory metal known. These lamps give a white light, with a consumption of only 1.5 watts per candle. A disadvantage to this type of lamp is that the filaments are very fragile.

In 1910 Messrs Siemens introduced incandescent lamps with filaments of drawn tungsten. At first they were only obtainable in small sizes for low pressures, but soon the range was extended, and lamps were produced of moderate candle power for normal pressures. These lamps take only 1 to 1.25 watts per candle, and are capable of withstanding

a considerable amount of rough usage and vibration.

In 1913 it was announced that an organised research conducted in the laboratories of the General Electric Company of America had resulted in the production of a new metal filament lamp consuming only half a watt per candle. The chief peculiarities of the lamp are that the bulbs are not exhausted, but are filled with some inert gas such as nitrogen, and the filament of drawn tungsten is used wound in the form of a fairly close spiral. The high efficiency and intensely white light result from the extremely high temperature to which the filament is raised. If such a high temperature were permitted in a bulb which was exhausted of air in the usual way, it would quickly blacken owing to the evaporation of the filament. The presence of an inert gas reduces the amount of evaporation, though it has the disadvantage of augmenting the amount of heat conducted away from the incandescent filament. In virtue of the spiral form given to the filament, however, the loss of heat by conduction through the gas is prevented from seriously detracting from the enhanced efficiency resulting from the extremely high temperature to which the filament is heated.

The claim that these gas-filled lamps only consume half a watt per candle has proved to be too optimistic. To obtain a satisfactory life it is necessary to run them at a somewhat lower temperature corresponding to a consumption of 0.65 to 1 watt per candle-power according to size. Compact filaments as used in gas-filled lamps have decided advantages for projection work.

The *pointolite* or arc-incandescent lamp forms an intermediary between incandescent and arc types. In this lamp an arc is maintained within a hermetically-sealed glass bulb. The light is emitted from a little solid ball of tungsten, so approaching closely to the ideal of a point-source of light. The efficiency attained is of the same order as that previously quoted for gas-filled lamps. An important and interesting feature is the ingenious method of striking the arc. This is accomplished by ionising the gap between the electrodes. The emission of ions is obtained by electrically heating a little rod of certain rare earths by closing an auxiliary starting-circuit which is interrupted as soon as the gap between the electrodes has been rendered sufficiently conductive to start the arc.

An important difference between carbon filaments and metallic filaments is that the metallic filaments have a much lower specific resistance, and hence must be made longer and finer than a carbon filament suitable for the same pressure. This requires that very special attention be given to the method of supporting the metal filaments, and makes it difficult to produce a satisfactory metal filament lamp of low candle power for high pressures. Another distinction between carbon and metallic filaments is that the resistance of a metallic filament increases with rise of temperature, whereas that of a carbon filament falls. The result is that the brightness of metal filament lamps is less seriously affected by small variations of pressure, since the resistance changes in the direction calculated to preserve a uniform flow of current.

Incandescent lamps work well with either continuous or alternating currents. They are now made of all sizes, from the miniature lamps of one candle power or less which are employed in surgery, up to lamps of two or three thousand candle power. When a number of them are used together they are almost always grouped in parallel. In the electric lighting of a house, for instance, positive and negative main conductors, consisting of insulated copper wire, are led from the dynamo, and to these the

positive and negative branches are respectively connected, whose ramifications extend to every room. Wherever a lamp is to be placed a positive and a negative leading wire must come, and each lamp forms, as it were, a bridge between the positive and the negative side of the system. The difference of potential is nearly the same for all; it is a little less in the case of the more distant lamps, because a certain fall in the difference of potential is incurred through the resistance which the leading wires themselves offer to the passage of the current. This loss has to be kept within reasonable limits by making the sectional area of the leading wires great enough, and no serious difficulty is experienced in doing this when the lamps all lie within a few hundred feet of the source. But the difficulty becomes serious when distribution is attempted on a large scale. Not only is the loss of energy in the conductors then a large part of the whole energy supplied, but it may give rise to wider variations in the potential than can be tolerated. If the number of lamps in use in any district were nearly constant, so that a nearly constant current would flow through the mains leading to that district, it would be easy to allow for the fall of potential in those mains. But this fall is itself a variable quantity, depending on the amount of the local demand; and to keep the potential sufficiently constant requires mains of large size, the cost of which becomes prohibitory when the area of distribution is much extended.

In such cases it is necessary to resort to other methods of distribution than by a simple system of parallel mains and branches. A sufficient number of sub-centres may be taken over the area to be lighted, and each of these made the starting-point of a system of parallel conductors, the sub-centres themselves being fed from the central source, through independent mains, with currents which are regulated to produce the necessary potential at each sub-centre. Even then, however, if the sub-centres are widely distant from the source the loss of energy in the mains will be serious. In distribution over a large area there is an obvious advantage in very high potential, for the same amount of electrical energy is then conveyed by a smaller volume of current, and consequently with less loss in the conductors. An obvious way of utilising mains having a higher difference of potential between them is to employ two lamps in series. Objections to this simple expedient are that lamps can only be switched on in pairs, and if one of them breaks or becomes disconnected, the other lamp is also extinguished. These drawbacks have been ingeniously overcome by Hopkinson's 'three wire system,' for a description of which the reader must be referred to some of the works mentioned at the end of this article.

Another method also widely adopted is to convey the electric energy to sub-centres in the form of small currents at a high potential, and convert it there into low-potential currents suitable for domestic use. Two plans of doing this have been put in practice—one, by means of storage batteries, is suitable for continuous currents; the other, by means of transformers, is suitable for alternating currents.

Storage Batteries are cells consisting of large sheets or grids of lead, superficially coated with oxide, which are immersed in dilute sulphuric acid, and are polarised by the passage of the current. Peroxide of lead is formed on the positive plates, and spongy metallic lead on the negative. After being charged by the passage of the current the cells will act for a time as electric generators, giving a current in the opposite direction until the plates again become inactive, when they may be again charged. The electric energy given out when

the cells are discharging is somewhat less, but need not, if the cells are slowly charged, be very much less, than the energy expended in charging them. Each cell has an electromotive force of about two volts, and its internal resistance is made low by grouping a number of pairs of plates in parallel within a single cell (fig. 2). When such cells are used to convert an electrical supply from high to low potential, they are grouped in series while they are being charged, and the groups are then broken up into sections which may be discharged separately or connected in parallel for discharge. Apart from this use of storage batteries in electric lighting, they form a most valuable, but unfortunately very costly, adjunct in domestic and other installations for steadying the electromotive force of the supply when used as a shunt across the terminals of the dynamo, and for storing electricity for use during intervals when the dynamo is not running. Small storage batteries have been successfully employed as a means of providing portable electric lamps for use in houses, carriages, and especially in mines. The miner's lamp is a small storage battery weighing a few pounds, and is enclosed in a water-tight case no bigger than an ordinary lantern, in the front of which is fitted a small incandescent lamp protected by a stout glass cover.

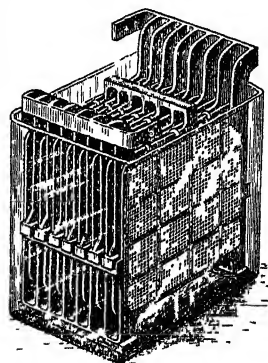

Fig. 2.

Transformers are induction coils, consisting of a core of soft iron on which two coils of insulated copper wire are wound. When alternating currents are made to pass through one of these, called the primary coil, they produce corresponding periodic alternations of magnetism in the iron, and induce alternating currents of corresponding period in the other or secondary coil. The effect of the iron is to increase the coefficient of mutual induction between the two coils. When the number of windings in the secondary coil is small compared with the number of windings in the primary coil, the electromotive force induced in it is correspondingly smaller than the electromotive force impressed upon the primary; and this is taken advantage of in practice in the conversion of a high-potential into a low-potential supply for electric lighting. In order that the iron core should have as much magnetic susceptibility as possible, it is made in the shape of a ring or some other closed (poleless) magnetic circuit, and to prevent waste of energy by the induction of currents in the substance of the iron, the core is laminated by being built up of thin plates or of wire, and in modern transformers a special steel alloy is generally used in place of iron, which combines permanently good magnetic properties with a high specific electric resistance. Even then, however, there is some waste of energy in the core on account of what is called magnetic hysteresis in the periodic changes of magnetism it undergoes, and some further waste occurs through the heating of both the primary and secondary coils in consequence of the resistance they offer to the conduction of the currents.

Notwithstanding these sources of loss the efficiency of a modern transformer is seldom less than 95 per cent., and in transformers of large size, such

as 1000 kilowatts capacity and upwards, working under favourable conditions, as much as 98·5 per cent. of the energy expended in the primary coil may be given off in the converted currents from the secondary.

It is common practice to immerse transformers in a tank containing mineral oil. The oil helps to keep the transformer cool by conducting the heat away to the walls of the tank, and also improves the insulation. Transformers immersed in oil in this way have been constructed to give pressures as high as 1,000,000 volts for testing purposes.

In early practice the current was in many cases reversed as often as 200 times per second, which fact is generally expressed by simply saying that the 'frequency' (meaning frequency of complete alternations per second) was 100. A frequency of 50 has now become very general for lighting and power purposes, but the still lower frequency of 25 is still found in many districts. Frequencies below 40 are unsuitable for lighting on account of the flickering which then becomes apparent at each reversal of the current.

Distribution of electricity for the purpose of lighting by means of transformers, high potential being used in the conveyance of the currents from the distant source, with conversion to low potential before use, was first effected on a fairly large scale in America.

Powerful electric 'search-lights' have long since become indispensable for naval purposes; see NAVY.

Among the minor adjuncts in electric lighting, an important part in guarding against possible risk of fire is played by the 'cut-outs,' whose function is to interrupt the current in any main or branch conductor should it ever exceed a safe strength—as might happen in the event of an accidental cross-connection or short-circuit being formed between the wires. The usual form of cut-out is a safety fuse, consisting of a short piece of foil or wire made of lead or of some fusible alloy which any dangerous excess of current will melt, and so interrupt the current, in that portion of the system which is guarded by the cut-out, before any damage is done. Cut-outs are generally put at the junction of branch with main wires, as well as in the mains themselves. Where the amount of current to be passed is large, an electro-magnetic cut-out is often preferred to a fuse.

Numerous forms of meter have been devised for measuring and recording the quantity of electricity supplied to consumers, some suited for continuous currents only, and others for alternating as well as continuous currents. Space does not admit of any description of the ingenious meters invented by Ferranti, Aron, and others.

References.—The early literature of electric lighting consists mainly of papers published in scientific and technical journals, for the most part since 1878, among which may be mentioned: J. Hopkinson in *Inst. Civil Eng. Lectures* (1883) and *Proc. Royal Soc.* (1887), G. Kapp in *Proc. Society of Telegraph Engineers* (1888) and *Mm. Proc. Inst. Civil Eng.* (1889), and G. Forbes in *Journal of Society of Arts* (1885, 1886, and 1889); Fleming, *Electric Lamps and Electric Lighting* (1899). Electric Railway. The proposal that electricity should furnish motive-power on railways is nearly as old as the railway-system itself. In

1837, when it was still doubted whether steam locomotives would come into general use, an experiment in electric traction was made by Robert Davidson, who propelled a car on the Edinburgh and Glasgow Railway by an electro-magnetic engine, with a galvanic battery to supply the current. But the cost of producing electricity on a large scale by means of a battery is so great as to make such a method of locomotion impracticable, however perfectly the electric energy may afterwards be converted into mechanical work. And the electro-magnetic motor of those days was an extremely inefficient machine, which did not succeed in utilising more than a small fraction of the electric power supplied to it. The matter consequently fell into complete abeyance, and was not revived until engineers had at their command a much cheaper mode of producing electric energy, and a much more efficient mode of turning it to mechanical account. This came about with the introduction of the Dynamo-electric Machine (q.v.), which gave a cheap means of converting work done by a steam-engine or any other prime mover into the electrical form, and with the recognition that the operation of the dynamo was reversible—that it would serve as a motor, to do mechanical work by the agency of the electric current. Hence it became practicable to work a railway electrically, by having at one station a dynamo to produce the current, driven by a steam-engine, turbine, or any other source of power, and by using this current to drive another dynamo, as a motor, upon the train, electrical connection between the train and the source of supply being maintained by means of conductors with which the train should be kept in contact throughout its course.

This was first demonstrated on a practical scale at the Berlin Exhibition of 1879 by Werner Siemens, who made and worked with complete success a line 219 yards long, on which three carriages, carrying twenty people, ran at a speed of about 7 miles an hour, by means of the current from a fixed dynamo, which was driven by a steam-engine. The current reached the car through a special conducting rail placed between the wheel-rails, and insulated from the ground by blocks of wood. The motor on the car took the current from this rail by the rubbing contact of copper brushes, and the circuit was completed through the car wheels and the ordinary rails. In 1881 a permanent electric tramway, $\frac{1}{2}$ mile long, was established at Lichterfelde (Berlin), where a still simpler plan of conducting the current was employed: the two ordinary rails, insulated from the ground and from one another by wooden sleepers, formed the two conductors.

The first really successful electric railway was the Portrush line in Ireland, 6 miles long and 3-foot 6-inch gauge, opened in 1883; the first line in America was opened a year later, and from that time forward the growth of electric railways has been continuous. Among the more important developments in this country may be mentioned the City and South London tube railway, 1887; the Liverpool overhead railway, the whole length of the docks (6 miles, with fourteen stations), 1893; the Central London tube railway, $6\frac{1}{2}$ miles long, from Shepherd's Bush to the Bank; the Mersey Railway and the District Railway from Ealing to South Harrow (5 miles), both electrified in 1903. The first application of electric traction in place of steam on the main railway systems of the country began in the following year (1904), when the Tynemouth branches of the North-eastern Railway and the Liverpool and Southport branches of the Lancashire and Yorkshire Railway were both electrified. Slowly but surely the other great railway companies are following suit by electrify-

ing portions of their systems over which the passenger traffic is sufficiently dense.

The plan of using the rails themselves as the only conductors is obviously impracticable, except on very short lines and in special circumstances, on account of the difficulty of maintaining good insulation. Of the various methods which have been employed for keeping the moving car or train in continuous electrical contact with the source of supply, three in particular deserve mention. In the first place there is the so-called 'overhead system,' in which a bare copper wire is carried on posts above the track, connection being made by a wheel mounted at the extremity of a trolley-pole which projects from the roof of the car. This is the system nearly always adopted for electric trams which have to run along public thoroughfares. A notable exception is the tramway system of the London County Council. In this case, instead of a single wire suspended overhead, two stiff conductors are carried on insulators in a conduit constructed between the rails, the collector or 'trailer' which makes the necessary sliding contact passing down through a narrow slot in the top of the conduit. The third and last system of which mention can be made is that commonly found on electric railways. A third stiff conducting rail is used, raised from the ground on insulating supports, sometimes between the running rails, but more often on one side and rather above the level of the other rails. A metal brush projecting from the side of the car leads in the current from the insulated 'live rail' to the motors. In common with the 'overhead system,' the return path for the current is through the wheels to the running rails. This is not the case, however, in the 'conduit system' of the London County Council. Here there are two separate insulated conductors in the conduit, with which continuous contact is maintained, one of which acts as the return, and no current flows into the tram-lines. As there is danger from electric shock to any one who may accidentally step on the live rail of an electric railway, this system can only be allowed when the line is private property and completely shut off from the general public; for instance, level crossings cannot be tolerated across a railway electrified on this system. Continuous current and alternating currents, both single and multiphase, have all been successfully applied for purposes of electric traction; but by far the greater number of electric trams and trains in this country are propelled by two or more direct current series wound motors. Generally gearing is introduced so that the motors rotate at a higher speed than the driving-wheel axles, but in some cases the armatures are fixed directly on the driving-axles.

To obtain the full benefit of electric traction it is essential that two or more separate motors should be employed in order to secure economical operation of the motors at a low speed as well as at full speed. This object is attained by connecting the motors in series when starting or travelling at slow speed, and altering the connections so that the motors are in parallel when full speed is acquired. Suitable resistances are also introduced at starting and in the transition stages between the series and parallel arrangements in order to check the large currents that would otherwise flow. The necessary changes in the connections are all made in proper sequence by simply turning the handle of a switching apparatus called the 'controller.' As currents of considerable magnitude have to be broken in switching over from one step to the next, destructive arcing is liable to occur at the controller contacts. For this reason it is usual to arrange a strong magnetic field, obtained by making the current taken from the line pass through the coil

of an electro-magnet in such a way that the interaction between this field and the current in the arc bridging the retreating contacts blows out the arc almost as soon as it is formed.

Besides the saving of electric-power effected by the so-called 'series-parallel control' just described, a further advantage of having at least two separate motors on every vehicle is that the driving effort can be spread over two or more axles, and consequently nearly all the dead-weight can be made available for securing a good adhesion between the driving-wheels and the rails.

The difficulty encountered in a system of electrification employing continuous current only is that the pressure at which the current is picked up from the track is usually limited in this country to 600 or 750 volts. It is true that in France and certain other Continental countries 1500 volts is being standardised for main-line electrification, while America provides an example in which the pressure of the direct current picked up by the moving train is as high as 3000 volts. Still, even at 3000 volts the limit of distance is soon reached at which it becomes uneconomical to transmit direct current from a single central station.

The usual way of overcoming this difficulty is to equip the central station with high-pressure three-phase alternating current generators, and to transmit the electric energy in this form to a series of sub-stations arranged at intervals along the railway. In these sub-stations the high-pressure three-phase current is converted into direct current at 600 to 3000 volts as the case may be, in which form it is applied to the various sections of the line.

Many alternative schemes have been worked out for utilising the high-pressure alternating current transmitted from the power station directly upon the moving trains, so avoiding the complication of the sub-stations for transforming into low-pressure continuous current. If three-phase current is employed, the train can be propelled satisfactorily by induction motors, and certain Continental electric railways are operated on this system; but the advantages obtained by the elimination of the sub-stations are considerably offset by the necessity of having an extra rubbing contact maintained between the train and a high-tension conductor.

On the whole, the best way of applying high-pressure alternating current directly to the train seems to be by means of single-phase current and compensated single-phase motors either of the series or repulsion type (see article on *Dynamo-electric Machines*). The first examples of English railways equipped on this system are the Heysham, Morecambe, and Lancaster section of the London Midland and Scottish Railway and the Brighton section of the Southern Railway. Both these lines have a single overhead conductor supplied with alternating current having a frequency of 25 and a pressure of about 6600 volts. Transformers on the train reduce this high pressure to a low pressure suitable for the motors. A drawback to the system is that the electrical equipment of the train is rather heavy, which results in more waste of energy every time the train has to be stopped and started again from rest.

All the arrangements for electric traction that have been referred to above are *conductor* systems. Energy is continuously passing to the car through the conductor which maintains connection between the distant dynamo and the motor on the car, and any break of continuity of the conductor, or any failure on the part of the car to make contact with it, deprives the car instantly of locomotive power. The introduction of storage batteries (see *ELECTRIC LIGHT*) has made an alternative method of electric traction practicable—viz. the *storage* system, in which each car or train is self-contained as regards

power. In this system there are no conductors along the line, but each locomotive is furnished with a set of storage cells, which are charged from time to time by means of a station dynamo, and carry enough energy to last during the trip. (For electric motor-cars specifically so called, see the article MOTOR-CARS, where they are described.) In some cases the plan is worked by placing the cells under the seats of the car, in others by using a separate locomotive car to carry them and the motor. Its chief drawbacks are the dead-weight of the batteries and the cost of renewing these when they are worn out or injured by the rather rough treatment they receive on the road.

See Dawson, *Electric Railways and Tramways* (1897); Hanchett, *Electric Railway Motors* (New York, 1900); Bell, *Power Distribution for Electric Railroads* (N.Y. 1900); Herriek, *Electric Railway Handbook* (N.Y. 1901); Rider, *Electric Traction* (1903). Recent text-books on the subject are: Wilson and Lydall, *Electric Traction*, F. W. Carter, *Railway Electric Traction*, A. T. Dover, *Electric Traction*.

Electric Telegraph. See TELEGRAPH.

Electric Waves. See the latter part of the article ELECTRICITY, also ETHER, LIGHT, MAGNETISM, REFRACTION, &c.; and for their practical application in wireless telegraphy, TELEGRAPH.

Electric Welding. See WELDING.

Electro-biology is a term used both of Animal Electricity, discussed at ELECTRIC FISHES, and of Mesmerism, or a phase of Animal Magnetism (q.v.).

Electrocution, a mode of execution adopted in the state of New York in 1888, and afterwards in various other states of the Union, by passing a current of electricity through the body. The condemned man is seated in a chair, and one electrode applied to his head, the other to the calf of the leg. The word is irregularly formed in imitation of *execution*.

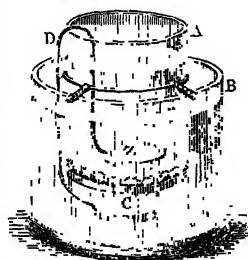

Electrolysis. See ELECTRICITY.

Electro-magnetism. See MAGNETISM.

Electro-metallurgy is the art of depositing, electro-chemically, a coating of metal on a surface prepared to receive it. It may be divided into two great divisions—electrotype and electroplating, gilding, &c., the former including all cases where the coating of metal has to be removed from the surface on which it is deposited, and the latter all cases where the coating remains permanently fixed. Gold, platinum, silver, copper, zinc, tin, lead, cobalt, nickel, can be deposited electrolytically.

Electrotype is the art of copying printing type, woodcuts, seals, medals, engraved plates, ornaments, &c. by means of the galvanic current in metal, more especially copper. Suppose we wish to copy a seal in copper; an impression of it is first taken in gutta-percha, sealing-wax, fusible metal, or other substance which takes, when heated, a sharp impression. While the impression—say, in gutta-percha—is still soft, we insert a wire into the side of it. As gutta-percha is not a conductor of electricity, it is necessary to make the side on which the impression is taken conducting; this is done by brushing it over with plumbago by a camel-hair brush. The wire is next attached to the zinc pole of a weakly charged Daniell's cell, and a copper plate is attached by a wire to the copper pole of the cell; or, as is now usual, the current required is supplied by Dynamo-electric Machines (q.v.). When the impression and the copper plate are dipped into a strong solution of the sulphate of copper, they act as the - and + electrodes. The copper of the solution begins to deposit itself on the impression, first at the black-leaded surface in the vicinity of the connecting wire, then it gradually creeps over the whole conducting surface. After a day or two on the old method—

after a few hours when the magneto-electric is used—the impression is taken out; and the copper deposited on it, which has now formed a tolerably strong plate, can be easily removed by inserting the point of a knife between the impression and the edge of the plate. On the side of this plate, next the matrix, we have a perfect copy of the original seal. If a medal or coin is to be taken, we may proceed in the same way, or we may take the medal itself, and lay the copper on it. In the latter case, the first cast, so to speak, that we take of each face is negative, showing depressions where the medal shows relief; but this is taken as the matrix for a second copy, which exactly resembles the original. The adhesion between the two is slight, and they can be easily separated. The cell of a battery is not needed to excite the current.

A galvanic pair can be made out of the object to be coated and a piece of zinc. The figure shows how this may be done. B is a glass vessel containing sulphate of copper; A is another, supported on B by a wire frame, and containing a weak solution of sulphuric acid. The glass vessel A is without a bottom, but is closed below by a bladder. A piece of zinc, Z, is put in the sulphuric acid, and a wire, D, coated with insulating varnish, establishes a connection between it and the impression, C, which is laid below the bladder. Electrotype is of the greatest importance in the arts; by means of it duplicates in copper of pages of type are obtained, as is done with this Encyclopædia; engraved copper plates may be multiplied indefinitely, so that proof-impressions need be no rarity; woodcuts can be converted into copper; bronzes can be copied; and similar applications are made of it too numerous to mention. By connecting a copper plate ready for corrosion with the + pole, and making it a + electrode, it can be etched with more certainty than with the simple acid, and without the acid fumes.

Electroplating.—This is the art of coating the baser metals with silver by the galvanic current. Theoretically simple, it requires experience and skill. Articles that are electroplated are generally made of brass, bronze, copper, or nickel silver. When Britannia metal, iron, zinc, or lead is electroplated, it must be first electro-coppered, as silver does not adhere to the bare surface of these metals. Articles to be electroplated are first boiled in caustic potash to remove any adhering grease; they are then immersed in dilute nitric acid to dissolve any rust or oxide that may be formed on the surface; and they are lastly scoured with fine sand. Before being put into the silvering bath, they are washed with nitrate of mercury, which leaves a thin film of mercury on them, and this acts as a cement between the article and the silver. The bath where the electroplating takes place is a large trough of earthenware or other non-conducting substance. It contains a weak solution of cyanide of silver in cyanide of potassium (water, 100 parts; cyanide of potassium, 10 parts; cyanide of silver, 1 part). A plate of silver forms the + electrode; and the articles to be plated, hung by pieces of wire to a metal rod lying across the trough, constitute the - electrode. When the plate is connected with the copper or + pole of a one or more celled galvanic battery, according to the strength required, or subjected to the magneto-electric current, and the rod is joined with the zinc or - pole, chemical decomposition

immediately ensues in the bath, the silver of the cyanide begins to deposit itself on the suspended objects, and the cyanogen, liberated at the plate, dissolves it, re-forming the cyanide of silver. According, then, as the solution is weakened by the loss of the metal going to form the electro-coating, it is strengthened by the cyanide of silver formed at the plate. The thickness of the plate depends on the time of its immersion. The electric current thus acts as the carrier of the metal of the plate to the objects immersed. In this way, silver becomes perfectly plastic in our hands. We can by this means, without mechanical exertion or the craft of the workman, convert a piece of silver of any shape, however irregular, into a uniform plate, which covers, but in no way defaces, objects of the most complicated and delicate forms. When the plated objects are taken from the bath, they appear dull and white; the dullness is first removed by a small circular brush of brass wire driven by a lathe, and the final polish is given by burnishing. The process of electro-gilding is almost identical with that of electroplating. Success in either is attained by proper attention to the strength of the battery, the strength of the solution, the temperature, and the size of the + electrode.

Electro-deposition of other metals is similar in principle to electroplating. Gold (see GILDING) is deposited by a current from solution in aqua regia; copper from copper sulphate; zinc (in 'electro-galvanising' iron) from zinc sulphate; nickel (in 'nickel-plating') from nickel ammonium sulphate.

In a wider sense electro-metallurgy includes all processes in which electric current is used for metallurgical purposes, whether by its heating effect, as in welding, or the Electric Furnace (q.v.); or by electrolysis (see ELECTRICITY), as in obtaining metals from ore or waste material; or by both combined, as when the current fuses and electrolyses the ores of aluminium.

Electrometer. See ELECTRICITY.

Electron. The name given by Dr Johnstone Stoney to the smallest charge of electricity carried by an atom of matter; the facts of Electrolysis (q.v.)—interpreted by Faraday and Maxwell—serving to show that this was an indivisible unit or atom of electricity. In the years 1897-99 Sir J. J. Thomson demonstrated the separate existence of negative electrons, or corpuscles, in rarefied gas when conveying an electric current; and the nature of the corpuscle was found to be independent of the nature of the gas. He showed that these particles had 'mass' (see MATTER), but of amount so small that a thousand of them would not equal that of an atom of hydrogen, the lightest known particle of ordinary matter. Whether electrons have 'weight'—i.e. whether they are gravitationally attracted by the earth like ordinary matter—is still unknown. There is good reason to maintain, on the strength of experiments by Kaufmann and others, that the mass or inertia of an electron is explicable electromagnetically—i.e. that it is explicable in terms of the magnetic field generated by any moving charge. This theory, when worked out, fixes the order of magnitude for the size of the nucleus or centre of force which constitutes an electron, which turns out to be about the hundred-thousandth part of an atom in diameter, thus being by far the smallest individual particle known or suspected. The size of the electron and its charge and mass have been ascertained, with great experimental accuracy, by Professor Millikan in America. Ordinary electrification is the result of an excess or defect of electrons.

The positive electron has not yet been certainly

discovered, but the unit of positive charge is known to be a very small massive atomic nucleus, 1850 times as heavy as an electron, and therefore comparatively stationary, while electrons can revolve round it. Such a positive unit is called a proton. A single proton is a hydrogen nucleus; four constitute the nucleus of helium; and other combinations occur at the centre of other atoms. The properties of the proton have been chiefly elucidated by Sir Ernest Rutherford. The present view of the constitution of matter is that it is composed or built up of definite groupings of electrons and protons in equal numbers.

Electric conduction through metals—possibly thermal conduction also—is believed to be due to the locomotion of a crowd of electrons through atomic interstices, in a state almost free, or passing so easily from one atom to another as to be practically free. In electrolysis, they only travel by carrying the atoms with them; but in a vacuum tube they are flung from the negatively charged terminal or cathode with enormous velocity, against the positive terminal as a target, and produce the various effects of bombardment observed by all experimenters, and elucidated by Crookes in and about 1879.

When these projectiles are suddenly stopped in a sufficiently high vacuum, moreover, they not only heat or render luminous the target which they strike, but the stoppage of each is accompanied by a momentary pulse or shiver of ether, which travels out with the speed of light, penetrating many opaque bodies to a surprising depth, and producing the other effects discovered initially by Lenard, and more conspicuously by Röntgen (q.v.).

All radiation, on the classical theory, is believed to be due to the acceleration or change of motion of electrons, ordinary light being due either to their orbital rotation, or to perturbation of those orbits by what may be called 'chemical clash.' The theory of electronic radiation we owe to Sir Joseph Larmor, *Ether and Matter*. The atomic theory of Professor Bohr of Copenhagen has accounted in accurate detail for the bright line spectra of the chemical elements, by supposing that round the nucleus of an atom are a number of possible stable orbits, and that it is only in dropping from one of these orbits to another that light of definite wave-length is emitted. See ATOM. The number of electrons belonging to each atom of the chemical series of elements was counted by Moseley, and the numbers range from 1 for the lightest element, hydrogen, to 92 for the heaviest element, uranium. The heavier elements are liable to instability, and occasionally fling away electrons and protons, thereby degrading or stepping down, to become lower elements in the series. In this way radium ultimately becomes lead. The subject will be found treated in Sir J. J. Thomson's *Discharge of Electricity through Gases*, in Sir Oliver Lodge's book called *Electrons*, in Rutherford's *Radioactivity*, and also more recently in Professor Millikan's book *The Electron* (Univ. of Chicago Press). See ELECTRICITY.

Electrophorus, an instrument for obtaining electricity by means of induction. A tin mould, kept in connection with the ground, is filled with shell-lac or resin, and has a movable metal cover with a glass handle. When the surface of the resin or shell-lac is smartly beaten with cats' fur, this electrifies the resin negatively. When the cover is brought near the lower part of the apparatus, it is charged positively on its under surface, negatively on its upper. If then it is touched, the negative escapes, and the cover is charged with + electricity; and if removed and applied to any conductor, it will give a positive charge to the conductor. This may be often re-

peated with but small diminution of the original charge in the lower part of the apparatus, save by connection or dampness. The earth connection may also be made by other means.

Electroplating. See ELECTRO-METALLURGY.

Elegit, a writ by which a judgment creditor is put in possession of the land of the debtor; as contrasted with a writ of *Fieri Facias* (q.v.) to the sheriff to levy the debt.

Elegy (Gr. *elegeia*), properly a song of lamentation, came even amongst the Greeks to be used of any poem written in distichs. The alternation in elegiac verse of hexameter with pentameter helps to give to this species of poetry its character; but many poems have been written in this form which are not elegies proper. Few Greek have come down to us. Among the Romans, Catullus, Propertius, Tibullus, and Ovid were elegiac writers. Tibullus brought the erotic elegy to its highest perfection. In England the term elegy is applied to any serious piece where a tone of melancholy pervades the sentiments, as in Gray's famous *Elegy* (see GRAY). It includes also such splendid tributes to the dead as the *Lycidas* of Milton, the *Adonais* of Shelley, the *In Memoriam* of Tennyson, the *Thyrsis* of Matthew Arnold, the *Ave atque Vale* of Swinburne. There are collections of English elegies by W. F. M. Phillipps (1879) and J. C. Bailey (1899).

Elemental Spirits. See SYLPHS.

Elements, CHEMICAL, the simplest known constituents of all compound substances. Chemists regard as elementary substances or elements only those substances which have not been proved to be compound. It is not inconceivable that some of the substances at present designated elements (for list of known elements, see ATOMIC THEORY) may hereafter be proved to consist of more than one simple kind of matter, but in the meantime they are correctly called elements, as that term is applied above. The elements are somewhat arbitrarily divided into non-metals and metals, the latter forming by far the larger class. There is no sharp line of demarcation between the two classes, several elements occupying positions on the border line. The elements long classed as non metals were: Hydrogen (in chemical relations behaving like a metal), chlorine, bromine, iodine, fluoiline, oxygen, sulphur, selenium, boron, nitrogen, phosphorus, carbon, silicon. But the list was increased by the discovery of helium and argon (1895), and krypton, neon, and xenon (1898). Many hold that all the elements are composed of one fundamental elementary substance (see CHEMISTRY, PHYSICAL CHEMISTRY, METALS, RADIUM, ATOM, MATTER). For the time-honoured 'Four Elements' of the Greeks—air, fire, water, earth—see EMPEDOCLES. The 'Shoo-king,' a Chinese work older than Solomon, has five elements—water, fire, wood, metal, earth. The Indian Institutes of Mann have also five—subtle ether, air, fire, water, and earth.

Elemi, a fragrant resinous substance, is obtained from the pitch-tree, *Arbol de la Brea*, a native of Manila. Formerly many varieties of elemi, such as Mexican, Brazilian, and Mauritius elemi, were in the market, but these have now been supplanted in Great Britain by the original substance, that obtained from Canarium. Manila elemi, when pure and fresh, is colourless, and resembles in consistence old honey, but it is usually found mixed with impurities, hard, and of a yellow tint. It possesses an aromatic odour resembling that of a mixture of lemon, fennel, and turpentine, and when distilled, yields as much as 10 per cent. of essential oil. When treated with cold alcohol, it partly dissolves, leaving about 20 per cent. of a white resinous substance called Amyrine. Elemi is never used

internally, and only seldom as a stimulating ointment to old wounds.

Elephant, a genus of mammals in the order Proboscidea, now represented only by two species. These two survivors of a once numerous and widely distributed order occupy a zoological position of peculiar isolation, but they are connected by the

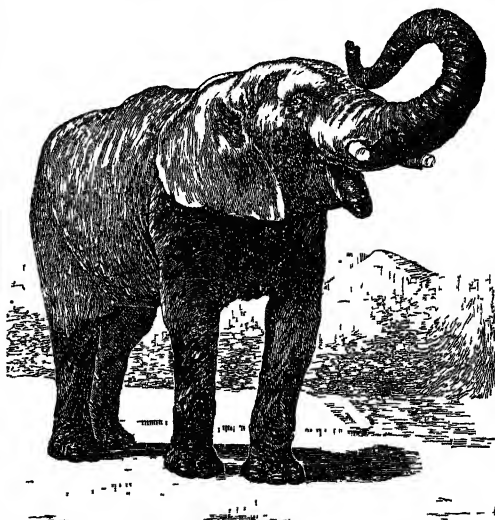

Fig. 1.—African Elephant ('Jumbo').

extinct Mastodon and Dinotherium to Coryphodon and the Dinocerata, and further back still to a probable origin among primitive hoofed or ungulate animals. The modern elephants—African and Indian—are quite distinct from one another, and are sometimes referred to separate genera (fig. 2). Like other giant animals, they are becoming gradually restricted in distribution and numbers, a fact of course hastened by the demand for the ivory of their tusks.

Principal Characters.—In some of their structural features, especially in nose, skull, and teeth, the elephants are as highly differentiated as they are in general intelligence; while on the other hand the anatomy of their limbs and anterior venous system is simple and primitive. The huge size, thick skin, and scanty hairs; the enormous head with high rounded skull containing large air-spaces and with wide expanse for the insertion of muscles; the long, muscular nose or proboscis with the nostrils at the tip; the short stiff neck which makes the trunk such an advantage; the huge simple limbs and massive feet, are conspicuous features. The brain is not much larger than man's, but as one would expect from the elephant's cleverness, is richly convoluted; the hind portion or cerebellum is, however, uncovered like a rabbit's. The teeth consist (1) of a pair of enormous, ever growing upper incisors or tusks, composed mainly of the precious dentine or ivory; and (2) of the large plated molars, the final result of a long series of historical differentiations, six on each side above and below, but never represented by more than one in full use at a time. The upper parts of the stout limbs are very long, so that the knees especially are situated far down; the five toes are inclosed in a common hoof which is very massive, the circumference of the fore-foot measuring about half the height at the shoulder. More technical characters are the presence of two superior venæ cavae, the simple stomach and large cæcum, the abdominal situation of the male organs, the two-horned uterus,

deciduate zonary placenta, and the position of the two teats upon the breast. The diet is vegetarian, and the animals are gregarious. An elephant may weigh 3 to 4 tons, and live 120 years, though the average seems to be about eighty.

The Two Species.—The Indian Elephant (*Elephas indicus*) is now restricted to the forest-lands of India and south-east Asia, including Ceylon and Sumatra. The African Elephant (*E.* or *Loxodon africanus*) inhabits the greater part of the African continent south of the Sahara. The contrast between the two species may be indicated as follows:

INDIAN.	AFRICAN.
Ears of moderate size.	Ears 3½ feet long by 2½ feet broad.
Molar teeth with folds parallel.	Lozenge-shaped folds
Trunk ends in finger-shaped upper lobe.	Lobes of trunk apex nearly equal.
Concave forehead.	Arched forehead.
Four or five nails on the hind-foot.	Three nails on the hind-foot.
Males about 10 feet at shoulder.	Males about a foot higher.

For extinct forms such as the Mammoth (*Elephas primigenius*), nearly allied to the Indian species, for the ancient British forms, for the Pigmy Elephant (*E. melitensis*), and for other Proboscidea, the reader is referred to the articles MAMMOTH and MASTODON.

Habits: Food.—The elephants use their trunks in gathering leaves, branches, and herbage, which they pass dexterously to the mouth. The Indian elephant eats the leaves of the palm, fig, and jak trees, &c.; the African form is fond of the succulent mimosa. Most kinds of palatable vegetable food, from sugar-canes to coco-nuts, are acceptable. Those brought to Britain are largely fed on hay and carrots. They prefer forest and mountainous regions; are ready to plunder rice and other crops, but seem to have a wholesome dread of fences.

Drinking.—Without bending head or limbs, the elephant dips the end of the trunk into the water, and fills it by a strong inspiration. The trunk is

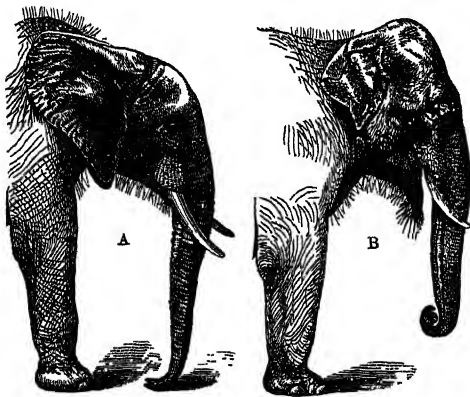

Fig. 2.—Heads of (A) African and (B) Indian Elephants

then inserted into the mouth and forcibly emptied. In the same way water or even sand may be blown over the body for cleaning and cooling the skin.

Locomotion.—The general leisurely and heavy tread of the elephant can be changed into a very fast trot or peculiar shuffle, especially when the males furiously charge their rivals or enemies. Their slow but sure progress is found most serviceable in difficult mountain travelling. Though one would hardly expect it, they undoubtedly have considerable powers of swimming. 'A whole herd

has been known to swim without touching bottom for six consecutive hours, rest a while, and then swim three more, with one rest.' When a herd with young ones is forced to take to the water, the mothers hold some up with their trunks, while others find a more comfortable position on their mothers' backs.

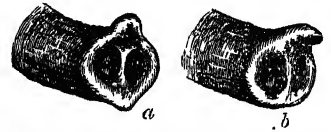

Fig. 3.—Tips of Trunks of (a) African and (b) Indian Elephants.

Herding.—Elephants are conspicuously social, a habit which has doubtless directly influenced their intellectual development. The herds are usually family parties; the mothers and young go in front, the males bring up the rear. The positions are reversed in alarm and danger. Both family likeness and family sympathies are often strongly marked. The leader is obeyed and also protected with much *esprit de corps*.

Breeding.—The males of both species are rather larger than the females, and excel in strength, endurance, and in the greater development of the tusks. A male is on this last account valued at one-fifth more than a female. In some localities—e.g. Ceylon, the female incisors remain very small, and the disproportion is always more marked in the Indian species. The male elephant is polygamous, and usually rules alone in the herd, expelling or killing his rivals. By means of such habitual contests the tusks have doubtless been perfected in strength. Except at the breeding season, the adult males live much by themselves, probably for selfish reasons rather than from love of solitude. At pairing-time a gland opening on the side of the head, between eye and ear, becomes especially active in the adult males, which are then said to be in 'must,' and are then well known to be probably the most dangerous of animals. The gland secretes a substance of strong musk-like odour, and is one of the numerous secondary sexual characters exhibited by animals. The fragrance is probably attractive to the female sex, though this must be a subsequent advantage, and not in any way a cause of the development of such an organ. 'The elephant,' Darwin observed, 'is reckoned the slowest breeder of all known animals, and I have taken some pains to estimate its probable minimum rate of natural increase: it will be under the mark to assume that it begins breeding when thirty years old, and goes on breeding till ninety years old, bringing forth three pair of young in this interval; if this be so, at the end of the fifth century there would be alive fifteen million elephants, descended from the first pair.' It is obvious enough that mortality and enemies, especially man nowadays, obviate any approximation to even such slow, natural increase of numbers. The elephant is one of the best examples of Spencer's law of the inverse ratio of individuation and rate of reproduction. Endless stories are told of the savageness of 'rogue' elephants, which seem chiefly to be males who have been expelled from the herd, and have in part the savageness of Ishmaelites, and in part the madness of enforced celibacy. The mothers manifest much maternal affection and care. One young elephant is born at a time, though occasionally twins may occur. There is a long (20½ months) period of gestation. The elephant sometimes breeds in captivity. Even after twenty years of menagerie life, birth is said to have occurred. In Siam and other parts of the East, breeding studs are kept up, but recruiting by fresh captives is always necessary. One of the baby Asiatic elephants born in America weighed 245 lb. at birth, and was about the size of a sheep.

It took milk for six months, and afterwards began to eat tender grass. The sucking is done as usual with the mouth, not with the trunk.

While the tusks of the male are much used in the customary contests with rivals, they serve other purposes. Thus Darwin notes: 'The elephant uses his tusks in attacking the tiger; according to Bruce, he scores the trunks of trees until they can be thrown down easily, and he likewise thus extracts the farinaceous cores of palms; in Africa he often uses one tusk, always the same, to probe the ground, and thus ascertain whether it will bear his weight.' The tusks are also used in ploughing the ground in search of bulbs. According to the position and curvature of the tusks, he either 'flings the tiger to a great distance—it is said to even 30 feet, or endeavours suddenly to pin him to the ground'—an action dangerous to the rider, if there be one, who is apt to be jerked off the howdah.

The trunk can be used in endless ways, to pull down a tree or snip a bunch of grass, to lift an immense weight or a pin from the ground, to fight or to fondle. Through it they make a loud shrill sound described by Aristotle as resembling the hoarse noise of a trumpet.

Intelligence.—Though the eyes are very small, they are quick to discern, and the other senses are highly developed. The elephants are also social animals. These two conditions, always favourable to intellectual development, are certainly here associated with a high degree of intelligence. Their memory both for friends and foes is strong, and has been more than once remarkably illustrated by tamed elephants, which, having escaped and been recaptured, returned with all their old obedience to their keeper. In higher mental qualities elephants are only excelled, according to Romanes, by dog and monkey. By dexterous blowing, an elephant made a potato, which had fallen out of reach, rebound against the opposite wall so as to return to an accessible place. Darwin observed similar experiments in the Zoo. Their dexterity in assisting human labour, their quiet submission to operations, the gusto with which decoys practise deceit, the manner in which they thatch their backs in summer to keep off sun and flies, their selection, shaping, and dexterous use of pieces of wood (implements) for leech-scrappers, fans, &c., their discriminating way of lifting and handling different materials according to their hardness, sharpness, (abstract ideas), &c., are all remarkable. To pile up materials round the base of a tree, so as to make a platform from which to reach an otherwise inaccessible enemy, shows decided power of rational device. An elephant has been known to feign death, and the working tamed forms are said to have an accurate sense of time. Of their capacity for learning tricks little need be said; to take tea at a table and ring for the waiter, to uncork bottles and drink the contents, or even to salute princes, puts more strain upon the elephant's patience than upon his intellect.

Emotions.—The elephant may be extremely gentle and affectionate, or when injured, both passionate and vindictive. They readily form friendships with their keepers, with children, or with fellow-animals, and sometimes manifest quite human tenderness. The partnership between the wild elephants and the birds which pick insects from their skin and rise screaming when alarm threatens, is obviously not disinterested. The better emotions, such as sympathy, appear undoubtedly to predominate, but there is no doubt as to their proverbial vindictiveness. The classic story of the tailor and the elephant has been repeatedly verified, in some cases with tragic results. As peculiarities of emotional tempera-

ment, Romanes notes the following: 'If a wild elephant be separated from its young for two or three days, though giving suck, it never after recognises or acknowledges it. The members of a herd are exclusive, a strayed stranger is driven off, and may thus become a "rogue" or "goondah." Such an Ishmaelite undergoes a transformation of disposition, becoming savage, cruel, and morose. He is possessed not by sudden bursts of fury, but by a deliberate brooding resolve to wage war on everything, and lies patiently in wait for travellers.' Elephants are also subject to sudden death from what the natives call a 'broken heart,' and which seems in some cases at least referable to psychical or cerebral conditions.

White Elephants.—Albinos occur among elephants as in other animals. In these the colouring matter of the skin is deficient; but the adjective white can hardly be used to describe the result. Their rarity has made them valuable, and they are revered as incarnations of Buddha. Holder notes 'that in the 16th century Pegu and Siam fought over one for many years, till five successive kings and thousands of men were killed, while Barnum in 1883 bought one in Siam which cost him \$200,000 by the time it reached America. Elephants vary slightly in the amount of hair on their characteristically naked hides. Those on high cool regions in India are said to have rather more hair, thus approaching the woolly extinct species of long past Arctic climates.

Hunting.—The elephant is hunted either for captivity, work, and pageantry, or for the sake of its ivory. The Indian forms are often captured alive in numbers by organised parties of four hundred or so natives, and the process is both tedious and costly. The herd is surrounded, and the circle narrowed by fires and watching. A strong fence and moat are made to form the so-called 'kheddah' into which the elephants are driven. There they are separated and hobbled by riders on tame elephants, whom the captives, curiously enough, do not touch. Single elephants are also noosed or decoyed by tame females; the pitfall method is too frequently fatal to be profitably employed if the elephants are wished alive. They are of course also hunted and killed both for sport and ivory. Sometimes, too, their ravages on cultivated ground have necessitated check. The shots are said to kill only on the forehead, temple, and behind the ear. The African elephant is followed either on horseback or foot, and some of the Arabs are said to be daring enough to face it with only sword and shield.

Uses.—The Indian elephant has been, and still is, much used as a beast of burden. In its half-domesticated state it becomes a patient and effective worker. They are of great service in lifting and carrying heavy burdens, which they hedge on to their tusks with the trunk. An ordinary elephant can carry half a ton continuously on a level road. In their natural state they often march for 20 miles to their feeding-ground or water-supply. In captivity they require a great deal of care and as much food. 'A large tusker needs 800 lb. of green fodder in 18 hours.' Their expensiveness, delicacy, and infertility are obstacles to domestication. The African elephant, anciently trained for war and pageantry, seems, contrary to the prevailing belief, to be still tamed and worked in the upper Congo basin. Some of the Duke of Mecklenburg's expedition (*From the Congo to the Nile and the Niger*, 1913) saw a herd of thirty, some of them at work, and photographed one ploughing.

Alexander encountered elephants in his campaigns; Semiramis is said to have made sham ones. In the Carthaginian wars, the Romans were at first disastrously affrighted by them, but with

familiarity learned to terrify them with torches. They captured several from Pyrrhus in 276 B.C. The Carthaginians are said to have used 140 elephants at the siege of Palermo; Hannibal took 37 over the Alps, where, according to Philemon Holland's quaint translation of Livy, they had 'much ado not to topple on their noses in the slabby snow-broth'; and the Romans themselves learned to use them. Even in modern times, in the East, they have continued to be so used, and in the Burmese war, though not actively engaged, elephants were found of great use both for transport and for clearing passages in the jungles.

Elephants have been almost equally used in pageantry and games. Caesar held elephant tournaments and employed them to draw chariots, while Nero characteristically matched an elephant against a single fencer. So too they have for many centuries held their place in the Juggernaut processions, and were remarkably displayed in honour of the visit of Edward VII. (as Prince of Wales) to India.

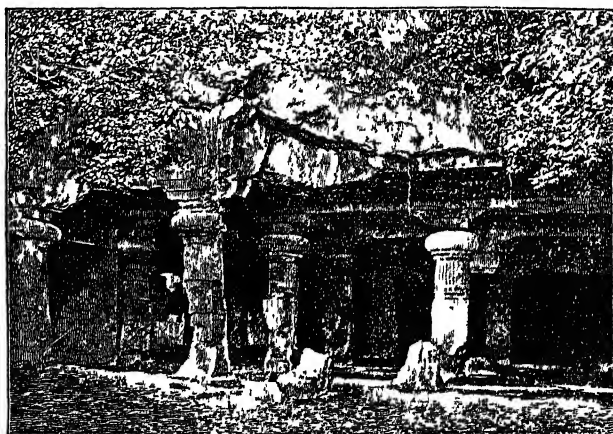

Ivory.—The tusks of an elephant may weigh 150–300 lb., and 'a famous tusk exhibited by Grote & Co., New York, measures 8 feet 11 inches on outside curve, has a diameter at the base of 6½ inches, and weighs 184 lb.' They have small 'milk' predecessors, but these fall out when the animal is very young. The true tusks are what are called rootless teeth, growing from persistent pulp, and owe their value to the large mass, elastic nature, and somewhat peculiar texture of the dentine portion (see **TEETH**). The enamel is very slightly developed, and only at the apex. See **IVORY**.

Proboscidean Fictions.—Under this title, Holder, in his interesting account of the 'Ivory King,' collects a number of the oddities erroneously recorded in regard to elephants. Thus it was long believed that they shed their tusks every ten years, but buyers of ivory can no longer have such comfortable assurance. Writers of the 14th century allude to the belief that they have two hearts, such extremes of temperament do they exhibit! From the low position of the knee-joint, the idea arose that the elephant's legs bend in opposite directions to those of other animals; while a different view is expressed by Ulysses in *Troilus and Cressida*: 'The elephant hath joints, but none for courtesy, his legs are for necessity, not for flexure.' Choicest by far, however, is the expression to a common belief exposed by Sir Thomas Browne in *Pseudodoxia Epidemica*—the elephant 'hath no joints, and being unable to lye down, it lieth against a tree, which the hunters observing do saw almost asunder, whereon the beast relying by the fall of the tree falls also downe itselfe, and is able to rise no more.'

Elephanta (native *Gharāpuri*), an island over 4 miles in circuit, in the harbour of Bombay, 6 miles E. of the city, and 4 miles from the mainland. It owed its European name to a large figure of an elephant which stood near its former landing-place, but which, after 1814, gradually sank into a shapeless mass. Of the island's far-famed Brahmanic rock-caves, four are complete, or nearly so; the most important is the Great Temple, still used by the Hindus on Sivaite festivals. It is entirely hewn out of a hard trap-rock, and measures 130 feet from north to south, and the same distance from east to west; the body of the cave forms a square of about 91 feet, originally supported by twenty-six columns, and sixteen half-columns, of

from 15 to 17 feet, many of which have been injured or destroyed. The most striking of its many sculptures is a three-headed bust of Siva, nearly 18 feet high and 23 feet round the eyes. This unique bust, like most of the other figures here, has been much defaced, and policemen are now employed to protect the cave. The caves most probably date from the 9th century.

Elephantiasis Arabum (also called *Cochin* or *Barbados Leg*, or *Pachydermia*) is a disease chiefly of tropical climates, and specially frequent in India. It consists in an overgrowth of the skin and connective tissue of the parts affected, with occasional attacks of inflammation resembling erysipelas. The disease (so called because the skin becomes like elephant's hide) is associated with, or caused by, obstruction of the lymphatic vessels of the affected part. In many cases a parasitic worm (*Filaria sanguinis hominis*) is found in the patient's blood, and is believed to cause the obstruction; but the disease may occur from other causes. The lower limbs and genital organs are the parts usually affected, and may attain an enormous size; the scrotum has been known to weigh over 100 lb. In the early stages it can sometimes be reduced or kept in check by firm bandaging, with careful avoidance of all causes

Caves of Elephanta—Entrance.

of irritation—e.g. over-fatigue, great changes of temperature. But in severe cases, amputation of the part affected is often necessary to allow the patient to move about at all. For the wholly distinct disease, *Elephantiasis Græcorum*, see **LEPROSY**.

Elephantiné (Arab. *Gezirat Asuān*, or *Gezirat-az-Zahr*, 'isle of flowers'), a small island of the Nile, 'a mosaic of vivid green, golden sand, and black syenite,' lying opposite to Assuan (q.v.), the ancient Syene, on the confines of Egypt and Nubia, in 24° 5' N. lat., and 32° 34' E. long. The ruins of the ancient city are traced in a large mound near the modern villages. From this island the Greek mercenaries were sent into Ethiopia by Psammetichus I. to recall the Egyptian deserters, and it was garisoned in the times of the Pharaohs, Persians, and Romans. The island was anciently called *Ab*, or the 'ivory island,' from its having been the entrepôt of the trade in that precious material. The most important ruins, preserved, till 1822, when they were mainly demolished to build a vandal governor's palace, were a late granite gateway of the time of Alexander III.; and a small temple dedicated to Khnum, the god of the country, and Sati, the goddess of the inundation, which was

built by Thothmes III. and his successors down to Amenhotep III. Another remarkable edifice (also destroyed in 1822) was the Roman Nilometer, mentioned by Strabo, which appears to have been built in the time of the Cæsars; several inscriptions still preserved record the heights of inundation from the time of Augustus to Severus. The island had the honour of giving a dynasty (the 5th) to Egypt, and was the capital of the first nome of the Southern Kingdom; the inscriptions on the rocks attest the adoration paid by Seti I., Psammetichus II., and other monarchs, to the local deities. Other interesting monuments have been found on this island; amongst which may be cited part of a calendar recording an important chronological datum—the date of the rising of the star Sothis, marking the beginning of the Egyptian year, in the reign of Thothmes III. (1445 B.C.); a Roman quay; and numerous inscribed potsherds—principally receipts in the Greek language—given by the farmers of the taxes in the reign of the Antonines. The population of the island is at present exclusively Nubian. There is a museum.

Elephant Island, an uninhabited island of the South Shetlands (q.v.), nearly completely covered with ice and snow, and almost entirely destitute of plant life, was discovered along with the other islands of the South Shetlands by a British trader in 1819. A landing there was first effected on 15th April 1916 by Shackleton's Antarctic expedition of 1914-16, after their great drift, first on the ice-bound *Endurance*, then on a detached ice-floe, and latterly in open boats. From here Shackleton with five men later made South Georgia in an open craft, and returned, after three abortive attempts, to the successful rescue of the hard-pressed members of his expedition, 30th August 1916.

Elephant-seal, or SEA-ELEPHANT (*Macrorhinus proboscideus* or *leoninus*), the largest of the seals, the male measuring about 20 feet in length. It occurs in the southern oceans off Patagonia, Juan Fernandez, Kerguelen, &c. The colour is grayish, the teeth relatively very small, the hind-feet without nails. The males are much larger than the

Elephant-seal (*Macrorhinus proboscideus*).

females, and have a tubular prolongation of the snout, dilatable in excitement. They live in families and societies, and feed on fish and molluscs, especially cuttle-fishes. The skin furnishes leather; the oil is valuable for burning; the tongue alone is palatable. Some distinguish a second, almost exterminated, species (*M. augustirostris*), found off the coasts of California and Western Mexico. See SEAL.

Elephant's-foot. See HOTTENTOT'S BREAD.

Elephant-shrew, a name applied to a number of long-nosed, long-legged Insectivora, forming the family Macroscelidæ. They are natives of

Africa, and are notable for their agile jumping over loose sand. They use their hind legs somewhat in kangaroo fashion. There are three genera, Macroscelides, Rhynchocyon, and Petrodromus.

Elettaria. See CARDAMOMS.

Eletz. See JELETZ.

Eleusine, a genus of Grasses, of which several species are of importance as cultivated cereals, notably *E. coracana* and *E. indica* in India, and *E. Toccus* in Abyssinia. *E. indica* is now common in the United States.

Eleusis, next to Athens the most important town of ancient Attica, on the Bay of Eleusis, opposite Salamis, was connected with the capital by the Sacred Road. It was famous as the chief seat of the worship of Demeter, whose mystic rites were here performed with great pomp and solemnity from the earliest authentic times till the era of Alaric, by whom the second and famous temple of the goddess, designed by Ictinus, one of the architects of the Parthenon, was destroyed. For the Eleusinian mysteries, see MYSTERIES. The site of the old Eleusis is now occupied by the little village of Lefkina, 16½ miles WNW of Athens by rail. Excavations carried on by the Greek Archaeological Society since 1882 have laid bare the whole of the sacred buildings, and the history of the great hall of mysteries can be traced. See Percy Gardner, *New Chapters in Greek History* (1892); J. G. Frazer's translation of *Pausanias* (1898); and *Eleusis*, by Phillios (trans. by Gatchell, 1906).

Eleuthera, one of the Bahamas (q.v.). For Eleuthera Bank, see CASCARILLA, CROTON.

Elevation, in Geology. See UPHEAVAL, VOLCANO.—In Astronomy and Geography, elevation means the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator, and is always equal to the latitude of the place. The elevation of a star, or any other point, is similarly its height above the horizon, and is a maximum when the star is on the meridian.

Elevation of the Host. See HOST.

Elevators (GRAIN) is the name given, especially in the United States, to erections for the transshipment of grain, and in which it is often stored for months, being weighed both when received and when sent out. Some of the largest are erected at Chicago and Buffalo. The grain on being received at the elevator is examined and graded, all of the same quality being kept together. The farmer or merchant who brings it receives an acknowledgment for so much grain of such a quality; and the grain which is delivered from the elevator on his account is grain of that quality, and not the same as he brought. In New York, floating elevators are frequently employed to transfer the grain from barges to sea-going vessels direct. Fixed elevators are generally built so as to be approachable by vessels on one or two sides, and have tramways running in on the level of the street; the chain of buckets which raises the grain moves, as the case may be, in an inclined plane passing through the wall to a vessel outside, or in a vertical plane into pits into which the grain has been shot from railway-trucks. The chain receives its motion from an endless band passing over one or two horizontal shafts in the upper part of the structure, the engine and boiler being located in a building outside the elevator itself.—Elevators in hotels, &c. are in Britain generally called Lifts (q.v.).

Elf. See FAIRIES.

Elf-bolts, flint arrow-heads (see FLINT IMPLEMENTS), long believed to be shot by elves, and therefore used as amulets.

Elgar, SIR EDWARD, O.M. (1911), was born 2d June 1857, at Broadheath, near Worcester. He played in orchestras, was bandmaster at the county lunatic asylum in 1879-84, and in 1885 succeeded his father as organist in the Roman Catholic Church, Worcester. An *Intermezzo* by him was produced at Birmingham in 1883. After a discouraging residence in London (1889-91) he returned to the west of England, and taught and composed at Malvern and at Hereford. He attracted a certain amount of notice by his *Frossart* overture, played at the Worcester Festival in 1890, by *Scenes from the Saga of King Olaf* (1896), *Caractacus* (1898), his cycle *Sea Pictures* (1899), and other works; but it was only in 1900, by his oratorio *The Dream of Gerontius*, that he gained world-wide recognition as one of the leading musicians of his time. In 1904 he was knighted. In 1905-8 he was professor of music in Birmingham University. Having made a new thing of oratorio in *Gerontius* and *The Apostles* (1903), he afterwards did the same for the violin concerto (1910) and for the symphony (1908 and 1911). During the Great War he produced many notable compositions, including the *Spirit of England* and *Carillons*.

Elgin, the county town of Elginshire, 5 miles by rail SSW. of its seaport, Lossiemouth, 37 ENE. of Inverness, and 178 N. of Edinburgh. It lies on the Lossie in the 'garden of Scotland'; and while it retains a few quaint old houses, two crosses, and its cathedral, bishop's palace, and other ruins, it brightened up much during the 19th century. The Elgin Institution was erected in 1832 as an almshouse and school, out of £70,000 bequeathed by Andrew Anderson (1746-1822), who from private had risen to be major-general in the service of the East India Company. Other edifices are Gray's Hospital (1819) and the adjoining asylum (1834-65), the county buildings (1866), the court-house (1841), the market buildings (1850), the academy (1800), and the parish church (1828), with a tower 112 feet high. The once glorious Gothic cathedral (1224-1538) was a cruciform structure, 289 feet long by 120 across the transept, with two western towers, and a loftier central spire (198 feet). It was partially burned in 1270, and again in 1390 by the 'Wolf of Badenoch'; was dismantled in 1568; and in 1711 was finally reduced to ruins by the fall of the great tower. The chapter-house, with its 'prentice pillar,' is noteworthy. The town itself has suffered much from fire, its partial destruction in 1452 at the hands of the Earl of Huntly giving rise to the proverb 'Half done, as Elgin was burnt.' Little remains of the royal castle, which in 1296 lodged Edward I. of England; its ruins are surmounted by a monument (1839-55) to the last Duke of Gordon. A royal burgh since the reign of David I. (1124-53), Elgin till 1918 united with Banff, Macduff, Peterhead, Inverurie, Cullen, and Kintore to return one member to parliament. Pop. (1831) 4493; (1921) 7776. See Mackintosh, *Elgin, Past and Present* (1914).

Elgin, a city of Illinois, on the Fox River, 36 miles WNW. of Chicago by rail, with good water power, large watchworks, and many other manufactures; pop. (1890) 8787; (1920) 27,454.

Elgin and Kincardine, EARL OF, Governor-general of India. James Bruce, eighth Earl of Elgin, and first Baron Elgin in the peerage of the United Kingdom (1849), was born in London, 20th July 1811. He was son of the seventh Earl of Elgin (1766-1841) who brought from Athens the collection of sculptures known as the 'Elgin Marbles.' As governor of Jamaica (1842-46), and as governor-general of Canada (1847-54), he displayed administrative abilities of the highest order. While on his way to China in 1857, as plenipotentiary extraordinary, he learned at Singapore the outbreak of the Indian mutiny, and promptly diverted the Chinese expedition to the aid of Lord Canning. The mission to China was delayed, but ultimately, after some military operations and diplomacy, issued in the treaty of Tientsin (1858). He also negotiated a treaty with Japan. In 1860 again a combined English and French force penetrated to the capital, and enabled Lord Elgin and Baron Gros to dictate a peace under the walls of Peking. In 1861 Elgin became viceroy of India, but died 20th November 1863. See his *Letters and Journal* (1872); and books on parts of his life by Laurence Oliphant (1859), Boumnot (1905), and Wrong (1905). His son, the ninth earl (1849-1917), born near Montreal, and educated at Eton and Balliol, was an active Liberal politician, and held numerous offices, including those of Treasurer of the Household, First Commissioner of Public Works, viceroy of India (1892-98), chairman of the commission on the churches question in Scotland (1905), and colonial minister in the Campbell-Bannerman cabinet (1905-8).

Elgin Marbles, ancient sculptures brought from Greece by the seventh Earl of Elgin, then ambassador to the Porte, and acquired for the British Museum in 1816 for £35,000. Elgin obtained a firman to examine, measure, and remove certain stones with inscriptions from the Acropolis of Athens, then a Turkish fortress. His agents, on the strength of this firman, removed the so-called Elgin Marbles, packed before Elgin's recall in 1803, but not finally conveyed to England till 1812. They are said to have cost the ambassador upwards of £74,000; and

Part of the Frieze of the Parthenon—Elgin Marbles.

both before the purchase by the government and afterwards, there was fierce controversy as to the artistic value of the statues, and Elgin's right to remove them from Athens. Lord Byron's view as to the unjustifiableness of the removal was shared by

many, who nevertheless believed not merely that the marbles were thus saved from great risks, but that they were now made vastly more accessible to students than they could have been in Athens during the troublous times that followed.

These sculptures adorned certain buildings on the Acropolis of Athens. The chief portions, which are from the Parthenon or Temple of Minerva, were designed by Phidias, and executed by him, or under his superintendence. They consist mainly of statues from the pediments, metopes, and a large part of the frieze of the cella (see ATHENS); a figure from the Elechtheum, and a statue of Dionysus, and part of the frieze of the Temple of Winged Victory. See the various publications of the British Museum.

Elginshire, or MORAY, a Scottish county extending 30 miles along the low shore of the Moray Firth. It is 34 miles long, and 488 sq. m. in area, a former detached portion having in 1870 been annexed to Inverness-shire, whilst a corresponding portion was transferred from that county to Elginshire. The surface has a general southward ascent, and attains a maximum altitude of 2328 feet. Rivers are the Spey, Lossie, and Findhorn; and of several small lakes much the largest is Lochindorb (2 miles by 5 furlongs). West of the Findhorn's mouth are the sand-dunes of Culbin, due to drifting chiefly in 1694, and some of them rising 118 feet (see DRIFT). The predominant rocks are crystalline in the south; next Old Red Sandstone, with fish remains; and then reptiferous sandstone of (probably) Triassic age (see DICYNODON). Agriculture is highly advanced over all the flat fertile lower tract; still, only about one-third of the entire area is in cultivation. Bughead and Lossiemouth are fishing-villages; and whisky is distilled in the higher districts. Moray and Nairn shires return one member to parliament. Pop. (1801) 27,760; (1841) 35,012; (1921) 41,561. The ancient province of Moray included the counties of Elgin and Nairn, with parts of Banff and Inverness shires. Scandinavians early gained a footing; and it did not become an integral part of the Scottish kingdom till the later half of the 12th century. Antiquities are the Roman remains of Burghead, Elgin cathedral, Sueno's Stone (Fores), Kinloss Abbey (1150), Pluscarden Priory (1230), a Romanesque church at Birnie, and the castles of Duffus, Lochindorb, and Spynie, the last with memories of Bothwell. See histories by Shaw (1775) and Rampini (1897), and C Matheson, *Moray and Nairn* (1915).

Elgon, a volcanic mountain mass, 40 miles square, on the Kenya-Uganda boundary, 50 miles NNE. of the Victoria Nyanza, first visited by Joseph Thomson in 1883; highest point of the crater's rim, 14,140 feet above the sea. The southern slopes show a series of vast caves, partly artificial.

El Hasa. See ARABIA.

Elias Levita. See LEVITA.

Elie, a pretty little watering-place of Fife, 23 miles NE. of Edinburgh (by rail 44). The so-called Elie rubies, found on the beach, are garnets. Pop. 1500, or, with the adjoining burgh of Earlsferry, 2200 (one-half visitors).

Élie de Beaumont. See BEAUMONT.

Elijah, one of the greatest of the prophets of Israel, flourished during the reigns of Ahab and Ahaziah (circa 870-840 B.C.). The story of his career is told in 1 Kings, xvii.-xix., xxi.; 2 Kings, i., ii.; 2 Chron. xxi. 12-15. His main effort was directed to save Israel from lapsing into heathenism, and especially to thwart the efforts of Ahab and Jezebel to establish Baal-worship. The narrative of his life is full of human interest. His victory over the prophets of Baal on Mount Carmel is one of the most dramatic scenes in the Old Testament,

and the record of his despair and flight to Horeb, where he receives a revelation from God in a 'still small voice,' one of the most pathetic. The great figure of Elijah so impressed itself upon the Jewish imagination that a belief grew up that he would return to earth to herald the advent of the Messiah, and Jesus himself said of John the Baptist, 'This is Elijah that is to come' (Matt. xi. 14). See Milligan, *Elijah, his Life and Times* (1887); and Cheyne, *The Hallowing of Criticism* (1888).

Elimination, in Algebra, is the operation which consists in getting rid of a quantity or letter which is common, say, to two equations, by forming out of the two a new equation, in such a way as to make the quantity in question disappear. In complicated equations, elimination becomes difficult, and often impossible. Elimination is an important process in other sorts of reasoning besides the mathematical; in this larger acceptance, it means the setting aside of all extraneous considerations — of everything not essential to the result. In astronomical observations, the elimination of errors of observation is often effected by repeating the observations several times in such a way as to cause the errors to be of opposite kinds, then adding the observed values, and taking their average. — The word to 'eliminate' is often erroneously used in the sense of to 'elicit,' or bring to light.

Eliot, CHARLES WILLIAM, president of Harvard University, was born in Boston in 1834, and was educated at Harvard, where he filled some minor posts, and was president from 1869 to 1909. Under his rule the university was doubled in strength, and the old prescribed curriculum was finally abandoned for an optional system of studies. President Eliot is LL.D. of Williams, Princeton, and Yale, and has published, with Professor Storer, two manuals of chemistry.

Eliot, GEORGE. This is the *nom de guerre* of the great English novelist, who is perhaps best known as the author of *Adam Bede*. She was born on 22d November (St Cecilia's Day) 1819, and died on 22d December 1880. Her baptismal name was Mary Ann Evans, but she usually signed herself Marian Evans. She was the youngest daughter of the second family of Mr Robert Evans, a land-agent in Warwickshire, on the property of Mr Francis Newdigate. Mr Evans was at the time of the child's birth living at Arbury Farm, on the Newdigate property. Four months later he removed to Griff on the same property, 'a charming red-brick, ivy-covered house,' and here the afterwards celebrated authoress lived during the first twenty-one years of her life. Robert Evans was a man of strongly-marked and strenuous character, many of the leading traits of which were transferred by his daughter to the characters of Adam Bede in the novel of the same name, and of Caleb Garth in *Middlemarch*. But as Mr Evans died in 1849, and George Eliot's first work of fiction was produced in January 1857, the father was never made aware of the character of the daughter's genius. Of the life at Griff, many of the features are given in the sketch of Maggie Tulliver's and Tom's childhood in the *Mill on the Floss*; and especially her relation to her own brother Isaac, who was her senior by three years, is there powerfully painted. Her first school was at Miss Lathom's of Attleboro, where she remained between the ages of five and nine. Then she went to Miss Wallington's at Nuneaton, where the principal governess was Miss Lewis, with whom she formed a close friendship, and with whom she corresponded during those earlier years of expanding mind and receding faith, which intervened between her father's removal to Coventry in 1841 and his death in 1849. Between the ages of thirteen and

sixteen, she went to school at Miss Franklin's at Coventry, where she became for a time a fervent evangelical. She lost her mother, whom she loved devotedly, in 1836, when she was only sixteen; and early in 1837 her elder sister Christiana, who was five years her senior, and whose character and relation to herself are said to have been in some degree reflected in the Celia of *Middlemarch*, and in the relation between Celia and Dorothea in that tale, married Mr Edward Clarke, a surgeon, practising at Meriden in Warwickshire. From this time Mary Ann Evans took entire charge of her father's house. A master came over from Coventry to give her lessons in German and Italian, and another came to teach her music, of which she was passionately fond throughout life. But besides her studies in language and music, she was an immense reader on all sorts of subjects which interested her.

In the spring of 1841, when Mary Ann Evans, or Marian Evans, as she now called herself, was just of age, her brother Isaac married and took the house at Griff, her father removing to Foleshill Road, in the outskirts of Coventry. Here she became acquainted with Mr Charles Bray, the author of several works setting forth the philosophy of necessity from the plerological point of view, and formed a close friendship with his wife (*née* Caroline Hennell), as well as with her sister Sarah, and with her brother Charles Hennell, who had published in 1838 *An Inquiry concerning the Origin of Christianity*, from the rationalistic point of view. On 2d November 1841, Marian Evans announces to Miss Lewis, her evangelical friend, that she is about, as she hopes, 'to effect a breach in the thick wall of indifference, behind which the denizens of Coventry seem inclined to intrench themselves,' and her biographer, Mr John Cross (to whom she was married in 1880), says that 'this probably refers to the first visit paid by Miss Evans to Mr and Mrs Bray at their house in Coventry.' We understand it as anticipating some success in bringing her new friends to a more religious state of mind. If so, the result was just the opposite of her expectations. Before a fortnight had passed—i.e. on the 11th November, she writes to the same friend anticipating that Miss Lewis may feel estranged from her as a consequence of some revolution which was taking place in her own mind, and that the visit which Miss Lewis was to have paid to Miss Evans at Christmas may no longer be one which she would wish to pay; and before the end of the year she had so greatly offended her father by refusing to go to church that he actually formed, some intention, though he did not carry it out, of breaking up his household and going to live with his married daughter. Subsequently Marian Evans withdrew her objection to going to church, though she did not modify her views, and the breach between father and daughter was avoided.

At the opening of 1844, the work of translating Strauss's *Leben Jesu*, which had been at first undertaken by Mrs Charles Hennell, was transferred to Marian Evans, and at this she worked most laboriously till its publication in 1846. It was done in very scholarlike fashion. Indeed, the accuracy of George Eliot's work, whenever scholarship was needed, was all the more remarkable for her great imaginative power. There was nothing loose or slipshod about her. She may occasionally be fairly accused of pedantry, never of slovenliness, never of carelessness concerning facts, or of trusting to her imagination for what she had the means of verifying. She was painstaking by temperament as well as by self-discipline, though it would be difficult to find a case in which that very bad definition of genius, as 'an infinite

capacity for taking pains,' would be more wholly inapplicable. George Eliot had a vast capacity for taking pains, and she had also a great genius; but her capacity for taking pains was as distinct from her genius, and showed itself in intellectual achievements as different as *Silas Marner* from her translation of Strauss's *Leben Jesu*. She translated later Spinoza's *Tractatus Theologico-Politicus*, and in after-years his *Ethics*, though we are not aware whether either translation was ever published, certainly not with her name. On the last day of May in 1849 her father died, and on the 11th June Marian Evans went abroad with Mr and Mrs Bray, ultimately to Geneva, where she remained for some months, the Brays returning home without her. Towards the close of March 1850 she returned to England, crossing the Jura on a sledge, and reaching London on 23d March. She now began to write for the *Westminster Review*, and in September 1851, in the year of the Great Exhibition, she became its assistant editor, lodging at its headquarters in the Strand, and becoming the centre of the literary circle of which Mr Herbert Spencer and Mr G. H. Lewes were two of the most influential members. It was at this time that she translated Feuerbach's *Essence of Christianity*, the only book to which she appended her real name. The drift of this book was to show that (God is only a 'virtual' image of man, the magnified form of his hopes and desires.

Gradually her intimacy with Mr Lewes grew, and in 1854 she formed a connection with him which lasted till his death in 1878, a connection which was the great false step of her life. In July 1854 she went abroad with him, staying three months at Weimar, where he was preparing for his *Life of Goethe*. After a somewhat longer stay at Berlin, George Eliot and Mr Lewes returned to England, and took up their abode first at Dover, then at East Sheen, and then at Richmond. In November 1856, when she was just thirty-seven, she attempted her first story, *The Sad Fortunes of the Ren. Amos Barton*, the commencement of the *Scenes of Clerical Life*. The first part of it was published in *Blackwood's Magazine* in January 1857, and almost all who read it recognised at once that a new English author of great power had arisen. This story was quickly followed by *Mr Gilfil's Love Story* and *Janet's Repentance*. In 1858 she wrote *Adam Bede*, partly at home, partly abroad at Munich and Dresden, completing it at Richmond in November. After the publication of this brilliant story, which had the most marvellous success, George Eliot found to her amazement and annoyance that a Mr Liggins, who had lived in the same country as herself in the Midlands, claimed to be himself the author. There was a sharp controversy in the *Times* on the subject, and it was not till the publisher, Mr Blackwood, had intervened, that Mr Liggins's authorship was generally discredited. After the publication of *Adam Bede*, *The Mill on the Floss*, *Silas Marner*, *Romola*, and *Felix Holt* appeared in succession, but not rapid succession, for George Eliot always took her time, the last story coming out in 1866. Her first poem, *The Spanish Gypsy*, was published in 1868, followed in the next year by *Agatha*, *The Legend of Jubal*, and *Armigart*; and in 1871 appeared the first part of what proved to be, we think, in every sense her greatest work, *Middlemarch*. After that *Daniel Deronda*, published in 1876, showed a marked falling off in power, though many of the scenes are sufficiently rich in pathos, humour, and insight. Of the *Impressions of Theophrastus Such*, a volume of somewhat miscellaneous essays not unlike Thackeray's *Roundabout Papers* in their rather

vague structure, no good critic, we think, formed any very high estimate.

After the death of Mr Lewes, on 28th November 1878, George Eliot, who was always exceedingly dependent on some one person for affection and support, fell into a very melancholy state, from which she was roused by the solicitous kindness and attention of Mr John Cross (1840-1924), an old friend of her own and of Mr Lewes's, and to him she was married on 6th May 1880. Their married life lasted but a few months. George Eliot died in Cheyne Walk, Chelsea, on 22d December of the same year, and is buried in Highgate Cemetery, in the grave next to that of Mr Lewes.

As a novelist, George Eliot will probably always stand among the greatest of the English school; above Richardson, whom she greatly admired, and with whose painstaking and elaborate style of portraiture she had something in common, though in her preference for studies taken from simple rural life, from commonplace subjects so delineated as to bring out the humorous side of human shortcomings and the overmastering power of pitiable passions, she approached nearer to the still greater genius of Fielding. But her mind had not the movement and vivacity of Fielding's. If it had had that movement, that elasticity, that freedom of life in it, her genius would probably have shown itself much earlier than it did, and not waited till she was close upon forty before it betrayed even its existence. In early life she seems to have given her whole mind to the higher problems of life, and to have declared them virtually insoluble before she took refuge in portraying, with the wonderful power she actually displayed, the disappointments, the breakdowns, the narrow discontents, as well as the generous hopes and unsatisfied ideals of other human beings. She did not give the first-fruits of her intellectual energy to fiction. She exhausted, to her own thinking, the province of theology first, and having accepted with her usual too great docility the negative view of those who held that we have no trustworthy evidence that Christ's life was a revelation of divine power at all, and who held that Christianity is a mere dream dreamt in the idealising mood of eager human aspiration, she passed on sadly to a pitying study of man in the frame of mind of one who is determined to make the best of a bad business. And she extracted, perhaps, from our human lot all the good that it is possible for any one to extract from it who has once come deliberately to the conclusion that, though something may be done to elevate, and a good deal to alleviate it, and though not a little amusement may be extracted from it, yet that no power can really transfigure it, and that the more modest the aim, the less serious will be the inevitable disappointment. This subdued tone of regret that the highest human endeavour is destined to be baffled runs through all her tales, and it can hardly be doubted that their pervading melancholy is at least in some degree due to the false step which she herself, under the influence of a negative school of religious thought, had deliberately taken, when she sacrificed her own life to the ends of a connection out of which most of the joy, and almost all the sacredness, were taken by the unnatural and morally humiliating circumstances under which she entered upon it. It was greatly to her credit that, in spite of these circumstances, she steadily refused to lower the moral ideal at which she aimed, though she pursued it with scanty hope, and without the assistance of the faintest trust in the help of any higher power. She told her friend Miss Hennell in 1857, when the success of her *Scenes of Clerical Life* was already assured: 'If I live five years longer,

the positive result of my existence on the side of truth and goodness will outweigh the small negative good that would have consisted in my not doing anything to shock others, and I can conceive no consequences that will make me repent the past' (*Life and Letters*, vol. i. p. 461). She lived twenty-three years more; but the good of living up to one's own ideal is neither small nor negative, and the Life appears to show that the shock of having herself contributed to the world an example of a mode of life of which in her literary work she was constantly struggling to 'outweigh' the influence, was far greater and more enduring than she had at this time realised.

George Eliot's mind was one of extraordinary reflective power, but deficient in vivid personal instincts. She notices in *Silas Marner* how slowly impressions grow up within us, and how little we are sometimes aware of the origin of even those impressions which are destined to produce the greatest effects upon our character and external life. 'Our consciousness,' she says, 'rarely registers the beginning of a growth within us any more than without us. There have been many circulations of the sap before we detect the smallest sign of the bud.' In most men and women, such obliviousness of the first appearance of a germ of evil would hardly apply to a violation of wholesome instincts of that peculiar and marked kind by which she set her actual life at variance with her moral ideal. But perhaps it was so in her case. Her *Life and Letters* appear to show that the suave and long-drawn melancholy and somewhat artificial condition of self-repression in which she lived grew upon her more and more as 'the sap circulated' and fed her ideal of the true relation of husband and wife. In story after story she attempted to impress upon others the absolute sacredness of the relations to which her own action had apparently shown her to be indifferent. Her most impressive stories, *Adam Bede*, *Silas Marner*, *Romola*, *Felix Holt*, *Middlemarch*, and *Daniel Deronda*, were all penetrated with the desire to show how selfish and desecrating what is called love may be without marriage, and how equally selfish and desecrating marriage may be without love; yet at every return to that subject there seems to be less of hopefulness, less of awe, less of testimony to the sharp remorse which follows wrong-doing, less of vivid instinct, more of the tone of tragic warning, more of a tendency to acquiescence in inevitable misery, in her treatment of the theme.

Her pictures of the English farmers and tradesmen and the lower middle class generally of the Midland counties are hardly surpassed in English literature, and may be put on a level with Sir Walter Scott's similar pictures of the Scotch peasantry. Jeanie and Effie Deans in the *Heart of Midlothian* are hardly more impressive than Dinah and Hetty in *Adam Bede*, and many might plausibly contend that they are less so. George Eliot's drawing had finer touches, and was more from within; Sir Walter Scott's was more rapid and vigorous, and excited a deeper interest in the outward careers of his *dramatis personæ*. Then again, George Eliot's farmers and millers, and farriers and auctioneers, and parish-clerks, are painted not with more humour perhaps, but with humour of a rarer and finer kind, though it is less popular and effective than Sir Walter Scott's bailies and drovers, and dominies and gypsies. What George Eliot is too frequently deficient in is action; what Sir Walter lacks is depth of insight. But on the whole George Eliot's stories give us at least as good a picture of the life of the Midland counties, as masterly and full-length portraits of the slow-moving, beef-consuming, habit-ridden population of those counties in the earlier part of the 19th

century, as Sir Walter Scott has given us of the Border counties during the whole of the 18th century, with their wilder and more adventurous people. Of course there is a great difference in method between the two novelists, corresponding pretty closely to the difference between their favourite subjects. Sir Walter loved to show his favourites embarked in perilous adventures, Rob Roy gaining access to the Glasgow Tolbooth, and endangering his own neck to help a friend, or again, persuading the soldier to whom he was buckled to let him loose himself and dive for his life as they crossed the Forth. George Eliot on the other hand is seldom so successful as when she patiently develops her characters in rather slow but humorous dialogue—such dialogue as Shakespeare loved to interpolate in his plays when he chose to show us how the 'Goodman Dull' of the Midlands talked away in his stupid but comfortable self-satisfaction. Perhaps now and then George Eliot a little overdoes this microscopic view of inarticulate natures. In that curious short story of hers, *The Lifted Veil*, she gives a picture of a man with a quite preternatural insight into the vagrant and frivolous background of the minds of those amongst whom he lives, who is made to complain of 'the obtusion on my mind of the mental process going forward in first one person and then another, with whom I happened to be in contact; the vagrant, frivolous ideas and emotions of some uninteresting acquaintance . . . would force themselves on my consciousness like an importunate, ill-played musical instrument, or the loud activity of an imprisoned insect.' Had not George Eliot herself some curious gift of the same kind?—as for instance in the very long analysis she gives of the way in which the gossips of Raveloe constructed, out of their own consciousness, the dress and personal appearance of the pedlar who is supposed by them to have stolen Silas Marner's gold? She seems sometimes to have had the buzz of dull but excited gossip almost revealed to her by a kind of disagreeable intuition, and to have written it down at too great length in order to rid herself of its leaden predominance over her imagination.

But if in delineating character George Eliot is often more than the equal of Sir Walter Scott, because she goes deeper and has a more penetrating insight, she is greatly his inferior in play and richness of pictorial imagination, in rapidity of movement, and in warmth of colour. *Romola*, her one historical romance, though it is full of subtlety of conception, contains some very striking figures, and is painted with a surprising minuteness of realistic detail, is a doubtful success. Sir Walter Scott never failed in making the chief historical figure of his historical romances the most interesting figure in his group. His studies of Mary Stuart in the *Abbot*, of Elizabeth in *Kenilworth*, of James I. in the *Fortunes of Nigel*, and of Louis XI. in *Quentin Durward* are studies which will live in the imaginations of men as long as the most vivid of historical portraits. George Eliot did not thus succeed in painting Savonarola. It was in Tito and Tessa that she achieved her great successes. As regards the historical background of *Romola*, one can hardly say that it holds its place at all as compared with even the least successful historical romance of Sir Walter Scott, say, *Anne of Geierstein* or the *Fair Maid of Perth*. George Eliot's imagination was not buoyant enough to travel back into these far regions of history, and create them anew for us. Nor does her story move rapidly enough to make up for the difficulty of transporting our sympathies to so distant a region. We miss the vividness and we miss the action which are needful for the art of historical romance.

And again in her poetry George Eliot falls far

short of Sir Walter Scott; she is sombre, stately, even Miltonic after a fashion of her own, but Miltonic without Milton's felicity and charm. She is as grandiose as Milton without being as grand. Sometimes she attains true grandeur, as in her delineation of the selfishness that remained at the heart even of the inspired musician Jubal:

This little pulse of self that living glowed
Through thirce three centuries, and divinely strowed
The light of music through the vague of sound,
Ached smallness, still in good that had no bound.

The last line is grand, but not with Milton's sweet and winning grandeur. And usually George Eliot falls quite short of true grandeur in her poetry, and seems to be impressive without actually impressing the reader. The rhythm is laboured, the thought is laboured, the feeling is laboured, and the effect is more artificial than artistic.

Perhaps the most curious feature of George Eliot's genius is that she wrote so very much better and with so much more ease when she was writing dramatically than she did when she was writing her own thoughts in her own name. There is hardly a good letter—considered as a letter—in the whole three volumes, made up chiefly out of her letters, which Mr Cross gave to the world. There is on the contrary hardly an ineffective speech put into the mouth of any of the characters whom she delineated in her novels. Sir Walter Scott has given us a far larger *proportion* of ineffectively painted characters, though also a greater number of effectively painted characters, than George Eliot. There is hardly a country squire, or dairymaid, or poacher, or innkeeper, or country lad or lass to whom George Eliot does not give a thoroughly individual voice; but when she comes to speak for herself, her voice is measured, artificial, monotonous, and a little over-sweet. Her letters read as if they were turned out by machinery, though machinery invented by some gently intellectual and laborious mind. Scott's letters are delightful reading; Miss Brontë's are full of interest; even Miss Austen's, though they disappointed everybody, give the impression of a lively and observant mind. But George Eliot's have no freedom or personal stamp upon them, unless the absence of personal feeling be itself a personal stamp. It almost seems as if her mind had been intended more as an instrument for interpreting the minds of others, more as a phonograph through the agency of which the natures of all the various interlocutors with whom she met could be delicately registered and made to report themselves to the world, than as a distinct organ of her own taste and purpose. George Eliot is in the highest degree original in her power of interpreting others, but she gives an effect of faded second-hand suavity when she comes to interpret herself. Nevertheless she will be named in the same category with Sir Walter Scott, Thackeray, and Dickens.

See *The Life*, edited by J. W. Cross (3 vols. 1885-86), and works by Mathilde Blind (1883), O. Browning (1890), and C. S. Oloot (1911); also F. W. H. Myers, *Essays: Modern* (1883); R. H. Hutton's *Essays* (1871) and his *Modern Guides of English Thought* (1887); Sir Leslie Stephen's *George Eliot* ('Men of Letters,' 1902); G. Gardiner's *The Inner Life of George Eliot* (1912); and M. H. Deakin's *Early Life* (1913).

ELIOT, SIR JOHN (1839-1908), meteorologist, born at Lamesley in Durham, was second wrangler at Cambridge, and became professor of mathematics at Rurki and Allahabad and of physical science at Calcutta. He played an important part in organising meteorological work in India and elsewhere.

ELIOT, JOHN, 'the Indian Apostle,' was born probably at Widford in Hertfordshire in 1604, the son of a yeoman, graduated at Cambridge in 1622, and, after taking orders in the Church of England,

quitted his native country for conscience' sake, and landed at Boston in New England in 1631. For some months he 'exercised' in the church there, but being fore-engaged to friends who had settled at Roxbury, he repaired thither in the summer of 1632. In 1646, after two years' study of the language, he delivered a long sermon in the native dialect at Nonantum, about five miles from Roxbury; and other meetings soon followed. He shortly after began to establish his converts in regular settlements, his work meeting with approval both in the colony and at home; in England a corporation was founded in 1649 'for the promoting and propagating the Gospel among the Indians of New England,' which defrayed the expenses of the preachers and the cost of printing translations. At one time there were over a dozen townships of 'praying Indians' within the bounds of Massachusetts, and many more outside these limits, with numbers estimated in 1674 at 3600; but, although the organisation survived until the death of the last native pastor in 1716, the decay of the 'praying towns' was rapid after the war with a native king, Philip (1675), in which the converts suffered equal cruelties at the hands of their countrymen and of the English, whom they are nevertheless believed to have saved from extinction. Eliot died at Roxbury, 21st May 1690; there are monuments to his memory in the Indian burying-ground at South Natick, and at Newton, near the scene of his first Indian sermon. A man of earnest piety and devotion to evangelisation, warm-hearted, and of a singularly attractive manner, he has left a memory that is honoured among the first in the history of New England. Along with his colleague Thomas Weld, and Richard Mather, Eliot prepared an English metrical version of the Psalms, the 'Bay Psalm-book' (Camb. 1640), which was the first book printed in New England. He was also the author, among other works, of *The Christian Commonwealth* (Lond. 1659; suppressed by the general court, and now extremely rare), of *The Communion of Churches* (Camb. 1665; the first book privately printed in America), of several tracts, and of translations into the Indian tongue of Baxter's *Call*, Bayly's *Practice of Piety* (abridged), and Shepard's *Sincere Convert*. But the great work and the noblest monument of his devoted life was the translation of the Bible into the tongue of the Indians of Massachusetts (Algonquin), of which the New Testament appeared in 1661, and the whole work, with a version of the Psalms in metre, and a page of 'catechism,' in 1663. His *Indian Grammar Begun* was printed in 1666, his *Indian Primer* in 1669; a reprint of the only copy of the latter which can be localised, now in the library of Edinburgh University, was issued in 1880, along with a reprint of one of the only two extant copies (not alike) of *A Christum Covenanting Confession*. The finest collection of unique and scarce copies of Eliot's works is in the Lenox Library, New York; many of them have been reprinted.

The best Life of Eliot is that by C. Francis in vol. v. of the first series of *Sparks's American Biography* (1836), the earliest that by Cotton Mather (1691); see also two careful articles in the *Cyclopædia of Amer. Biog.* (vol. ii. 1887) and the *Dict. of Nat. Biog.* (vol. xvii. 1889).

Eliot, SIR JOHN, English statesman, the earnest champion of the supremacy of parliament in the government of the nation, was the son of a country gentleman of Cornwall, in which county, at Port Eliot on the Tamar, he was born, 20th April 1592. He studied for three years at Exeter College, Oxford. During the course of his continental travels he became acquainted with Villiers, afterwards Duke of Buckingham, an acquaintanceship which had a most important influence upon his

subsequent parliamentary career. He entered the parliament of 1624 as an adherent of Buckingham, whom he heartily supported in his warlike policy against Spain. But during the course of the next parliament (1625) his eyes seem to have become opened to the true character and designs of the favourite; he finally broke with him that same year, owing to an arrogant refusal on Buckingham's part to acknowledge the House of Commons as the real ruling power in the nation, and swung over to an extreme of fierce and implacable hostility. Accordingly, in the next parliament, in which, from the force of circumstances, Eliot was the leading spirit, his policy was in the main one of antagonism to the king, and finally culminated in the impeachment of Buckingham. For this Eliot was sent to the Tower on 11th May, and not released until the 19th. In the parliament of 1628 Eliot raised his voice against arbitrary taxation, and was instrumental in forcing from Charles the celebrated Petition of Right. For having again protested formally against the king's proceedings in matters of taxation and religion Eliot was, on 4th March 1629, sent, along with eight other members, to the Tower; and steadfastly refusing to acknowledge himself to have been in error, was kept in confinement until his death, on 27th November 1632. During his incarceration, Eliot composed an account of Charles's first parliament, *Negotium Posterorum* (first printed in 1881); a philosophico-political treatise, *The Monarchy of Man* (1879); and *An Apology for Socrates* (1881), a vindication of his own public conduct. He also left *De Jure Majestatis, a Political Treatise of Government*, and the *Letter-book of Sir John Eliot*, both published in 1882. See Life by John Forster (2d ed. 1871).

Eliot, SAMUEL (1821-98), United States author, born in Boston, graduated at Harvard, and was professor of History and Political Science in Trinity College, Hartford, in 1856-64, being also its president in 1860-64. Between 1864 and 1874 he lectured there and at Harvard, and he afterwards filled important posts in the Boston schools. The first two parts of a *History of Liberty* appeared in 1847-49-53. He also published a *Manual of United States History* (1856; revised ed. 1873).

Eliot, SIR THOMAS. See ELYOT.

Eliot, THOMAS STEARNS, poet and critic, was born at St Louis, Missouri, in 1888. Having graduated from Harvard, and studied at the Sorbonne and at Merton College, Oxford, he became a teacher and lecturer in London, where he has lived since 1913. *The Love Song of J. Alfred Prufrock*, his best poem, appeared in 1917; other longer poems are *Portrait of a Lady*, *Gerontion*, and *The Waste Land*. Eliot's verse, for the most part ironic and satiric, while brilliant in execution, is lacking in invention and poetic fire. *The Sacred Wood* (1920) is a work of literary criticism.

Elliott, GENERAL. See HEATHFIELD (LORD).

Elis, one of the ancient divisions of the Peloponnese, bounded N. by Achaia, E. by Arcadia, and W. by the Ionian Sea. The northern and more fertile region, watered by the Penæus and numerous smaller streams, was famed for the excellence of its horses; the southern and more rugged district is drained by the Alphæus, which rises in the mountains of Arcadia. On its banks were the grove and temple of Olympic Zeus, and the plain in which the great Olympic games were celebrated. For long the sacred character of Elis, as the seat of the greatest of the national festivals, protected the country from invasion, but during the Peloponnesian war, the Athenians, and afterwards the Spartans, disregarded the privileges of the Eleans. See OLYMPIA, for excavations.

Élisabethville, capital of the province of Katanga, in the SE. corner of Belgian Congo, near the Rhodesian frontier, is some 2300 miles from Capetown by rail. The district is rich in radium and copper.

Elisavetgrad, a fortified town of Ukraine, 180 miles N. of Kherson, is an important military depot, with a strong citadel. Flour-mills, soap, tallow, and candle factories are the principal works. Elisavetgrad was founded in 1754, and named after the Empress Elizabeth. Pop. 77,000.

Elisavetpol, or ELIZAVETPOL, or YELISAVETPOL, a town of the republic of Azerbaijan, on a tributary of the Kur, at an altitude of 1450 feet. The place is mean, but it has several mosques and churches, the mosque of Shah Abbas being particularly fine. Elisavetpol is not a healthy town; its inhabitants, about 60,000 in number, are compelled to retire to the hills in summer. The town and its vicinity are famous for their fruit-trees; and horticulture, the breeding of silkworms, and agriculture are the chief industries of the place. Elisavetpol (Gandzha or Kanga) formerly belonged to the Turks. The modern town was founded by Shah Abbas of Persia, but fell into the hands of the Russians in 1804. On 25th September 1826 the Persians were defeated here by the Russians under Paskevitch. The name Gandzha has been restored.

Elisha, a Jewish prophet and the successor of Elijah. His work extended over a period of fifty-five years during the reigns of Jehoram, Jehu, Jehoahaz, and Jehoash (*circa* 850-795 B.C.). The story of his life is told in 1 Kings, xix. 19; 2 Kings, ii-ix.; xiii. 14-21. Elisha lacked the originality of Elijah, and his career is far less dramatic, but his influence upon the political and religious life of the nation was far-reaching in its effects. The incidents recorded reveal him as a man of great sympathy and compassion, always eager to place himself at the disposal of the suffering and the needy.

Elixir (Arab. *al iksir*, 'the philosopher's stone;' see ALCHEMY), a term in pharmacy which has come down from the days of Alchemy (q.v.). By the alchemists the term was applied to various solutions employed in the attempt to transmute metals. But the most notable elixir, sought after by many, was the *elixir vitae*, 'the elixir of life,' that sublime, potent, perfect, invaluable preparation which, if discovered, would confer immortality or at least extreme length of life on him who drank it. The name has recently been appropriated to a class of American pharmaceutical preparations. These are very different from the old-fashioned elixirs, which corresponded in the main to our modern tinctures; for in the American elixirs the first object sought is to present the medicine under an agreeable form, even if frequently with a loss of potency. These newer elixirs are often highly alcoholic, and are sweetened and flavoured with great skill. In British pharmacy, *Elixir of Vitriol* is almost the only representative of the old class, and is prepared by mixing together sulphuric acid, alcohol, tincture of ginger, and spirit of cinnamon. This preparation, also known as aromatic sulphuric acid, is useful for quenching thirst, sharpening the appetite, checking profuse perspiration, and often reducing the action of the pulse. The dose may range from ten to forty drops, administered in syrup or water.

Elizabeth, the capital of Union county, New Jersey, formerly capital of the state, lies 5 miles SSW. of Newark by rail, with one quarter (generally called Elizabethport) on Staten Island Sound. It contains a court-house, city-hall, and several good schools, and is the seat of a large Singer sewing-machine factory, and of a number of manufactories of saws, chemicals, hardware, &c. Eliza-

bethport ships large quantities of anthracite coal; it also has several foundries. A great drawbridge over Staten Island Sound, 800 feet in length, with a draw-span 500 feet long, connects New Jersey here with the Staten Island shore. Pop. (1880) 28,229; (1890) 37,764; (1920) 95,783.

Elizabeth, Queen of England and Ireland, was the daughter of Henry VIII. by his second wife, Anne Boleyn, and was born in Greenwich Palace, 7th September 1533. From her father she inherited physical strength, resolution, energy, hauteur, a fiery temper, an inclination both to cruelty and to coarseness, and a passion for splendour; to her mother may be attributed such physical attractions as can be claimed for her, whatever of feminine piquancy flashed fitfully across her essentially masculine life, and probably also her insincerity, her jealousy, and her love of artifice. The marriage of her parents was a secret one, and when, in 1536, her mother was beheaded, and her father married Jane Seymour, she, as well as her half-sister Mary, the daughter of Catharine of Aragon, was declared illegitimate. Her early years were in consequence passed under a cloud, though profitably so far as intellectual discipline was concerned. The governesses and teachers, in whose society she spent most of her time till the death of her sister Mary, and of whom the chief were Lady Bryan, Lady Tyrwhitt, Sir John Cheke, William Grindal, and Roger Ascham, were almost all devotees to the New Learning, while some were adherents of those Reformation principles which her father partially accepted and established in England. Her accomplishments, like her charms, the ardour of her Protestantism, and even her patriotism and political foresight, were exaggerated by the historians-in-waiting of her reign. But it is beyond question that she learned to read Cicero, Sophocles, and even one or two of the Fathers in the original, to speak German and French with fluency, and to acquire a mastery over the then limited *technique* of music.

During the life of Elizabeth's father, two of her stepmothers, Anne of Cleves and Catharine Parr, looked upon her with a friendly eye, and the latter, but for her father's temper or dislike, would have had her much at court during the closing years of his reign. But till, on the death of Mary, she ascended the throne, she did not play an important part in English politics. During the reign of Edward VI. she, then a girl of sixteen, was subjected to the dubious attentions of Lord Seymour, High Admiral of England, and responded so far to them that her conduct was made the subject of a public inquiry. On her brother's death she took the side of her sister against Lady Jane Grey and the Duke of Northumberland, but her identification with Protestantism aroused the suspicion of Mary and her counsellors, and led to her being implicated in Wyatt's rebellion in 1554, and thrown into the Tower. Subsequently she was strictly guarded in Woodstock, and her adroit and seemingly not altogether insincere conformity to the Catholic ritual was probably the sole cause of her not sharing the fate of the leading Protestants of the time, and being sent to the block.

On the death of Mary, 17th November 1558, Elizabeth, then twenty-five years of age, was summoned to the throne amid the acclamation alike of Protestants, who saw in her advent a cessation to the persecutions of the preceding five years, and of Catholics, who had more than a suspicion of her indifference in ecclesiastical and theological matters. Although to the end of her life she retained a liking for the splendour of Catholic ceremonial, and had no sympathy with the doctrines of Geneva, her political sagacity enabled her at once to perceive that her part in Europe must be that of a Protestant sovereign, while her courage led her

to act promptly. Having presumably taken the advice of Sir William Cecil (afterwards Lord Burghley), whom three days after her accession to the throne she appointed Chief Secretary, she issued a proclamation to the effect that the church service be read in English, and the elevation of the host be discontinued. That she ordered the English ambassador at Rome to notify her accession to the reigning pontiff, Paul IV., is denied. Paul IV. maintained that Elizabeth, being illegitimate, must resign all pretensions to the crown of England, which he claimed a right to dispose of, that country being a fief of the holy see. The only result of this assumption was to make Protestantism and patriotism in England synonymous. The Anglican Church, with its Thirty-nine Articles, its Book of Common Prayer, and its acknowledgment of the headship of the sovereign, was there and then virtually established in its present form. The change that was effected was in no sense a revolution. Of the prelates who were in office when Elizabeth began her reign, only one, Kitchin, Bishop of Llandaff, agreed to the innovations contained in her proclamation, but of 9000 clergy, fewer than 200 resigned their livings.

To an exceptional extent, even for a sovereign with such strong absolutist instincts as Elizabeth, her life was bound up with the history of England (q.v.). Here, therefore, it will be necessary only to point out how her personal prejudices and opinions, and still more, her likes and dislikes, affected the policy of her country. The great blots upon her reign were the persecution of the Catholics, and the execution of Mary, Queen of Scots. As to the last, it is impossible now to say how much feminine jealousy on Elizabeth's part of a woman with greater personal attractions than herself had to do with the tragedy, but it is unquestionable that such jealousy existed. The discovery of designs against her life, such as the Ridolfi plot, had probably also not a little to do with her final determination, and certainly led to the execution of the Duke of Norfolk. The great glory of Elizabeth's reign, on the other hand, was the destruction of the Spanish Armada in 1588; but for this great national deliverance but slight credit is due to Elizabeth. It is true that, when an army assembled at Tilbury to resist invasion, she showed the courage of her race, and addressed her troops in language which has the genuine ring of patriotism. But it is also true that she at first declined to admit the national danger, although it was apparent to all her advisers, that she hesitated lamentably as to the steps to be taken to meet it, and that her parsimony in such matters as the naval commissariat led to the risk of disaster, and prevented the victory which was actually won from being so complete as otherwise it would have been. The triumph of England over Spain is to be attributed to the wisdom and energy of Elizabeth's advisers, to the skill and courage of the great English captains of the time, and to the generous patriotism of England, and especially of London, merchants.

It would be difficult to say whether the romantic side of Elizabeth's life is more notable for its prominence or for its farcicality, if not unreality. From her sixteenth year to her fifty-sixth, one matrimonial scheme or violent passion, not always remarkable for delicacy, succeeded another. Before she ascended the throne, her name was mentioned in connection either with marriage or with love, not only with Admiral Lord Seymour, as already mentioned, but with Edward Courtenay, son of the Earl of Devonshire; the Earl of Arran; Philip of Spain, who married Mary; and Philibert of Savoy. After she became Queen of England, Philip renewed his courtship, while her hand was also solicited by or for Eric, king of Sweden, Henry

III. of France, his successor Henry of Navarre, the Archduke Charles of Austria, and the Duke of Alençon. Letters preserved in Hatfield show that she cherished an attachment for the last until he died, worn out with debauchery, in 1584; although at the time they first met she was thirty-eight and he nineteen, and a dwarf with a face horribly disfigured by smallpox. But her heart was most profoundly touched by Robert Dudley, Earl of Leicester (q.v.), master of the horse, an accomplished courtier, and a handsome and clever, though dissolute and essentially shallow man. She indicated her partiality for him even before the death of his wife, the ill-fated Amy Robsart. The despatches of the Bishop of Aquila, ambassador of Philip II. in London, represent her indeed as accessory to the 'murder' of Amy, and as being willing to become a Roman Catholic, provided Philip consented to her marriage with Leicester. But the bishop violently disliked Elizabeth, and there is every reason to believe that he was befooled by her, while it is by no means certain that the death of Leicester's wife was the result of foul play. But it is unquestionable that Elizabeth would have married Dudley but for the remonstrances of her chief adviser, the elder Cecil. After Leicester's death, Robert Devereux, second Earl of Essex (q.v.), succeeded to his position as favourite. But Elizabeth's relations towards Essex, as indicated by outbursts of temper as well as of affection, were essentially those of a mother towards a spoiled child. When Essex was beheaded for rebellion in 1601 she does not seem to have exhibited much grief. The eccentricity of Elizabeth was shown even more in her passion for adulation and extravagance in dress than in her coqueries. Raleigh felt constrained to compare her in a breath to Alexander, Diana, Venus, Orpheus, an angel, and a nymph. She is Shakespeare's 'fair vestal throned by the west,' and Spenser's Gloriana. Paul Hentzner, a German, who saw her going to chapel when she was in her sixty-fifth year, says that at that time she 'had pearls with rich drops in her ears, wore false red hair, had a small crown on her head, her bosom uncovered, her dress white silk, bordered with pearls of the size of beans, a collar of gold and jewels.' So long as she retained any activity she attended theatrical and other pageants; and the more splendid these were, the more they were to her taste. The vigorous style of her dancing was commented on sarcastically by her enemies. The variety and number of her dresses have passed into a proverb. When every allowance has been made for the manner in which Elizabeth's charms were enhanced by her own artifices, and by the flattery of her courtiers, she must still be believed to have had some personal attractions. When young she was noted for her abundance of auburn hair and mobile though regular features, while Hentzner found her 'stately and majestic,' and remarked 'a special beauty in her delicate white hands.'

Patriotic as Elizabeth was after her own peculiar fashion, she was outside of and had no sympathy with either the intellectual or the religious movements of her time. Protestantism in the form of Puritanism she abhorred; she was indifferent to the genius of Shakespeare, though his plays were performed before her. She never advanced beyond the essentially classical studies of her girlhood; yet, in virtue mainly of translations from Greek, Latin, and French, she has been included by Horace Walpole in his *Catalogue of Royal and Noble Authors*.

A personal interest attaches to the last years of Elizabeth's reign, owing to her great loneliness. This was due in large measure to the fact that her leading advisers and friends, including Burghley, Walsingham, Hatton, Bacon, and Warwick, prede-

ceased her. Their places were taken by other men of ability, Sir Robert Cecil, Burghley's second son, being in particular both a skilful diplomatist and an accommodating courtier. But she never was on exactly the same terms with them as she had been with their predecessors. She also felt lonely in a political sense. She had inherited Tudor views as to the absolute supremacy of the crown over parliament. During the last thirteen years of her reign parliament assembled three times, in 1592, 1597, and 1601, and although, partly owing to her tact and partly to its timidity, no actual collision occurred between them, it protested against monopolies, and sought to curtail Elizabeth's expenditure. With such manifestations of public spirit Elizabeth could have no sympathy, and indeed she felt somewhat of a stranger in her own country, and among a people whose intellectual, religious, and even political ideas were widely different from, and in some cases diametrically opposed to, her own. Nevertheless, her indomitable spirit enabled her to retain her zest for the pleasures of life; to the last, too, she retained her indifference to the sufferings of others. As late as the year 1601 she was able to give receptions, to visit at the country-houses of wealthy subjects, and even to comport herself after the fashion of a hoydenish school-girl. Within a few weeks of her death a seminary priest of the name of Richardson was hanged and disembowelled at Tyburn. In the beginning of 1602 those immediately about her noticed a decline in her health. She revived temporarily, however, and was able to ride, hunt, and even dance once more. In the second week of 1603 she caught cold, and never recovered. In February she was seized with sickness, which was aggravated by melancholy. She would take no medicine and little food, refused to go to bed, and rested in silence day and night on cushions. She continued in this condition till March 24, when she died in the presence of her council. She had previously made a sign with her hands in answer to a question by Cecil, which was interpreted as indicating her wish to be succeeded by James VI. of Scotland.

'The golden days of good Queen Bess' are more than ever regarded as one of those periods of English history of which we have as a nation much reason to be proud. It is emphatically the period in which England took up her position as a 'world power,' and it is impossible to believe that Elizabeth had no personal part in making it what it was. The 'Virgin Queen,' it is true, stands revealed by history as cruel, capricious, insincere, at once unpleasantly masculine and weakly feminine, but she was highly popular with her subjects, and this popularity cannot be quite explained away by circumstances outside of herself. She had unquestionably the invaluable faculty—in her case it amounted almost to genius—of selecting as her advisers the most capable of the men around her.

See the *Lives* by A. Strickland (new ed. 1864) and Bishop Creighton (sumptuously illustrated, 1896; smaller reprint, 1899). M. Wiesener (Paris, 1878; trans. 1879) deals with her youth, and F. Chamberlin (1921) with her private character. The most reliable authorities on the public events of her reign are the calendars of the state papers, especially the calendar of the MSS. at Hatfield, and the calendar (1509–1603) of the state papers relating to Scotland. Among historical works dealing with this period, Froude's, in spite of the doubts which have been thrown on its accuracy by able critics, is still the best and most exhaustive. Hallam, Lingard, Birch's *Reign of Queen Elizabeth* (1754), Wright's *Queen Elizabeth* (1838), Beesly's *Queen Elizabeth* (1892), Motley's *Dutch Republic and United Netherlands*, and A. F. Pollard, *Political History of England*, vol. v. (1910) should also be consulted. Essays on Elizabeth are innumerable; that of Dr Jessopp (1889), contributed to *The Dictionary of National Biography*, will be found exceptionally bright

and comprehensive. See also the articles MARY QUEEN OF SCOTS; BURGHLEY, ARMADA, LEICESTER, ESSEX, DRAKE, RALEIGH; and for the Elizabethan Literature, see ENGLAND (LITERATURE OF), and DRAMA.

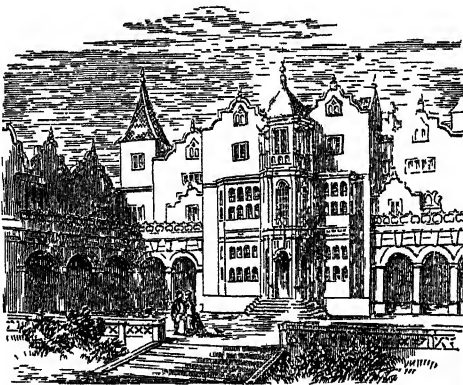

Elizabeth, Queen of Bohemia, forms the connecting link between the ancient royal families of England and Scotland and the present reigning dynasty. Daughter of James VI. of Scotland and I. of England, she was born in the palace of Falkland, 19th August 1596, educated in England, and in 1613 married to Frederick V. (q.v.), Elector Palatine, who in 1619 was chosen by the Bohemian estates to fill the throne of Bohemia. The following year the army of the 'Winter King' was routed by the forces of the Catholic League, and the royal family took refuge in Holland, where they had to endure sore poverty. Of the thirteen children of Elizabeth, mention may be made of Charles Louis, who was restored to the hereditary electorate at the close of the Thirty Years' War in 1648; Rupert, the 'mad cavalier'; Maurice, who also fought in England during the Civil War; and Sophia, who was married to Ernest Augustus of the House of Brunswick, afterwards Elector of Hanover. After the Restoration Elizabeth went to England, where she died February 13, 1662. When in 1701 the question of succession to the crown of Great Britain was debated, it was found that all the descendants of James I. were either dead or were Roman Catholics, except Sophia, Electress of Hanover, and her family. By act of parliament the crown was accordingly secured to her and her descendants, 'being Protestants;' and in virtue of this Act of Settlement, on the death of Queen Anne Sophia would have ascended the throne, but she predeceased the queen three months, and her son became king of Great Britain as George I., August 12, 1714. In this extraordinary and unforeseen manner did the unfortunate queen of Bohemia originate the dynasty of the reigning monarch. In her prosperity fond of luxury and magnificence, in adversity a devoted wife and mother, she was always resolute and vivacious, and exercised a singular charm over her contemporaries. See her *Life* in Mrs Everett Green's *Lives of the Princesses of England* (1851); Gardiner's *History of England*; and R. S. Rait's *Five Stuart Princesses* (1902).

Elizabeth, MADAME (1764–94), a French princess, sister of Louis XVI. (q.v.).

Elizabeth, ST, daughter of Andreas II., king of Hungary, was born at Presburg in 1207. At the age of four she was affianced to the Landgraf of Thuringia, Louis IV., and brought to his court in the Wartburg near Eisenach to be educated under the eyes of the parents of her future husband. She early displayed a passion for the severities of the Christian life. She despised pomp, and ambition, cultivated humility, and exhibited the most self-denying benevolence; her conduct even as a girl astonished the Thuringian court. The marriage took place when Elizabeth was only fourteen. Louis himself, far from blaming the devout girl whom he had made his wife for her long prayers and ceaseless almsgiving, was himself partially attracted to a similar mode of life. A boy and two girls were the fruit of their union. Louis died as a crusader at Otranto in 1227. Great misfortunes soon befell the saintly landgravine. She was deprived of her regency by the brother of her deceased husband, and driven out of her dominions on the plea that she wasted the treasures of the state by her charities. At last she found refuge in a church, where her first care was to thank God that he had judged her worthy to suffer. Subsequently, after other severe privations, such as being forced to take up her

abode in the stable of a hostelry, she was received into the monastery of Kitzingen by the abbess, who was her aunt. When the warriors who had attended her husband in the crusade returned from the East, she gathered them round her, and recounted her sufferings. Steps were taken to restore to the unfortunate princess her sovereign rights. She declined the regency, however, and would only accept the revenues which accrued to her as landgravine. The representations of other potentates soon induced her brother-in-law to allow her to return to Marburg, and to draw a yearly revenue of 500 marks. She now devoted herself wholly to a life of asceticism, put on nun's raiment, and took up her residence in a cottage at the foot of the hill on which stood her castle of Marburg. The remainder of her days were devoted to incessant devotions, almsgivings, and mortifications. All her revenues were given to the poor, and what she required she earned with her own hands. She died 19th November 1231, and was canonised four years after by Pope Gregory I. Miracles surrounded her even during her lifetime; thus a basket conveying provisions to the poor, when opened by a suspicious person, was found to contain nothing but roses. Above her grave at Marburg the beautiful Elisabethkirche was founded in 1236. See Montalembert's *Histoire de Sainte Elisabeth de Hongrie* (1836; 17th ed. 1880). Kingsley's *Saint's Tragedy* (1848) is based on the story of Elizabeth's life.

Elizabethan Architecture, a term applied to the mixed style which sprang up on the decline of Gothic architecture. It is chiefly exemplified by mansions erected for the nobility in the reigns of Elizabeth and James I., and originated in the first attempt to revive classic architecture. This tendency came from abroad, and was influenced, no doubt, by Holbein, who was patronised by

Holland House.

Henry VIII., and furnished several designs in this manner. John of Padua succeeded him, and built in the mixed style a palace for the Protector Somerset (for which purpose the cloisters of St Paul's were taken down), and the mansion of Longleat for his secretary, Sir John Thynne. At first the classic forms were applied to the details only, and the old English design was preserved, both as regards the plan and general aspect of the exterior; but by degrees the classic taste pervaded the whole design. Thus the bow-windows and turrets of the Tudor style are preserved, but their decoration is treated with classic cornices and pilasters instead of Gothic enrichments. The vast dimensions of the apartments, the extreme length of the galleries, and enormous square windows are leading characteristics

of this manner of building. The ornaments both within and without were cumbersome but picturesque, while the plaster ceilings wrought into compartments are amongst the most original and striking features. In short, the architecture was in keeping with the dress of the period, rich and gorgeous, rather than elegant and graceful; but the domestic arrangements and general planning of the houses were carried to a degree of completeness and comfort which has scarcely been exceeded since. The following examples of mansions of the 17th century may be still seen near London: Holland House, Campden House, Charlton, the Marquis of Salisbury's at Hatfield, and Knole, the property of Lord Sackville. The most eminent architects of those times were John Thorpe, Gerard Christmas, Rodolph Symonds, and Thomas Holt.

Elizabeth Petrovna, Empress of Russia, daughter of Peter the Great and Catharine I., was born in the year 1709. Of doubtful legitimacy, and apparently indifferent to everything but the gratification of her passions, she did not oppose the accession of the boy Peter II. in 1727, of Anna, Duchess of Courland, in 1730, and of the infant Ivan VI. in 1740. In 1741 the infant emperor was deposed, and Elizabeth raised to the throne, partly by the agency of Lestocq, a surgeon, and the Marquis de la Chétardie, the French ambassador. In the following year Elizabeth proclaimed as her successor Peter, the son of her sister the Duchess of Holstein-Gottorp. During this reign a war with Sweden was brought to a successful conclusion by the peace of Åbo. The anti-Prussian policy of her advisers and her personal animosity towards Frederick II. led her to take part in the war of the Austrian Succession and in the Seven Years' War, before the close of which she died in January 1762. Though prodigal in conduct, she was strict in the observance of the public ordinances of religion. Averse to business, she was guided by favourites, while corruption prevailed in every department of the state. She founded the university of Moscow and the Academy of Art at St Petersburg.

Elizavetpol. See ELISAVETPOL.

Elk, or **MOOSE** (*Alces machlus*, or *palmatus*), the largest living deer, a magnificent animal of circumpolar distribution, in Europe, Asia, and especially in America. It is the only species of its genus or sub-genus, but is nearly allied to *Cervus* (see *DEER*). It must be distinguished from the Wapiti (*Cervus canadensis*), with which it is often, verbally at least, confused. The adult elk usually stands about six feet high at the shoulders, and may exceed even this noble stature. The male bears very broad (palmate) divergent antlers, with which it has been known to kill a wolf at a single blow. The general colour is dark reddish-brown, but becomes slightly lighter and grayer in winter. The limbs, especially the fore-legs, are very long, and as the neck is short, the elk browses more upon bushes and the like than upon the ground herbage, which it is but little adapted to reach. The tail is very small. More detailed characters are the broad

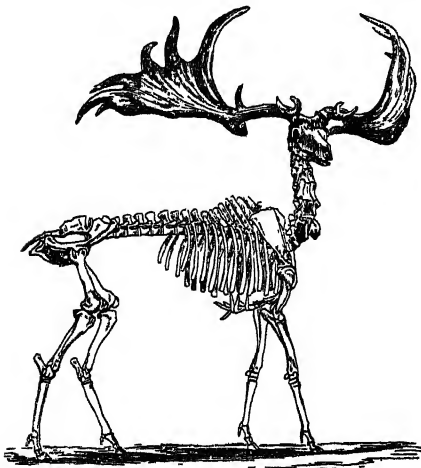

Head of Elk (*Alces machlus*).

hairy nostrils, the overhanging upper lip, the small eyes and tear-pits, the long and broad ears, the low stiff mane on the back of the neck, the loose mane on the lower side of the neck and on the breast, the long brittle hair, &c. The antlers form between them a sort of basin, for each broadens out in a great shovel-shaped expansion, with marginal prongs or snags, increasing as usual with the years of life. The entire 'head'—i.e. the pair of antlers—sometimes weighs 40 lb., while adult animals are said to weigh in all about 10 cwt. The young male elks do not begin to acquire antlers till they are nine months old, and growth seems to go on for fourteen years. The younger elks are also marked by a large goitre-like swelling under the throat.

Elks are for the most part solitary in their habits, except at the breeding season. They delight in marshy places and in forests. The widely separating halves of the hoof enable them to find firmer foothold in soft ground or among snow. In the forest, their magnificent antlers, as Darwin notes, must sometimes be rather in the way than otherwise. When walking leisurely, they carry themselves so well that entanglement is avoided, but it is easy to see how the case is altered when, with head thrown back, they flee before the wolves. The usual gait is a shambling trot, but the elk can also gallop rapidly. Only when the deep snow impedes it are the hunters, aided with snowshoes, able to run it down. The usual method of hunting is to steal upon the elk as it rests, but as its senses are extremely acute and the trails often confused, successful capture is regarded as a feat. Naturally timid and inoffensive, the disposition changes in the breeding season. The male elks fight with one another, and are at that season sometimes decoyed to the hunter, who imitates the sounds of a rival. As the elk is then furious, this device demands strong nerve and sure aim.

The European and Asiatic distribution of the elk is now much restricted. In Germany, for instance, they were abundant in the time of Cæsar, but are now all but extinct. In the Baltic states, in

Skeleton of Irish Elk (*Megaceros hibernicus*):
Height to summit of antlers, 10 feet 4 inches.

Northern Russia, in Norway and Sweden, they still occur, but not in the abundance which is still exhibited in North America. Domestication has been tried with success, and the animal trained to the sledge. The flesh is esteemed a good kind of venison; the fat is remarkably soft; the nose and tongue are reckoned delicacies. The skin is used for a variety of purposes. As the elk feeds largely

on leaves, buds, and bark, it does considerable damage to forest trees.

Elk, IRISH (*Megaceros giganteus* or *hibernicus*), a giant deer now extinct, known from the remains found in the Pleistocene diluvium of Middle Europe, Britain, and especially Ireland. It must have been a magnificent animal, standing about 6 feet high at the shoulders, and probably very like a fallow-deer. The antlers formed the most striking feature. They have their own peculiarities, but recall in part those of the quite distinct modern elk, and also those of the fallow-deer. Antlers have been found 5 feet in length, while a straight line drawn between the extreme tips in one specimen measured 10 feet 10 inches. In a specimen where the skull alone weighed 5½ lb. the antlers weighed 81 lb. Associated with such an enormous head-growth we naturally find large and strong neck vertebrae and fore-limbs. The skeletons are to be seen in most museums. See DEER.

Elkesaites. See EBIONITES.

El-khargeh. See OASES.

Elkhart, a city of Indiana, at the junction of the St Joseph and Elkhart rivers, 101 miles E. by S. of Chicago by rail, with flour-mills, planing-mills, machine-shops, and railway workshops and manufactures of musical instruments, paper, and starch. Pop. (1890) 11,360; (1910) 19,282; (1920) 24,277.

Ell (allied to elbow, Ger. *ellenbogen*, Lat. *ulna*, 'the forearm'), a measure originally taken in some vague way from the arm, and which has been used to denote very different lengths. The English ell, as a measure of cloth, is equal to 1½ yard (q.v.), the Flemish to ¾ yard, and the French to 1½ yard.

Elland, a town in the West Riding of Yorkshire, on the river Calder, 3 miles S.E. of Halifax by rail. It has some cloth-mills, and there are valuable stone-quarries in the vicinity. Pop. 10,500.

Ellenborough, EARL OF. Edward Law, first Earl of Ellenborough, was eldest son of the first Baron Ellenborough (1750–1818), Chief-justice from 1802 of the King's Bench. Born 8th September 1790, he entered parliament in 1813, held office under several administrations, and in 1841 was appointed Governor-general of India. He received the thanks of parliament in 1843 for his 'ability and judgment' in supporting the military operations in Afghanistan, but his treatment of the civil servants of the Company, and his policy of conciliating the natives by oriental display and proclamations which appeared to sanction idolatry, led to his recall in 1844. Supported by the ministry, he was created Viscount Southam and Earl of Ellenborough, and in 1846 was First Lord of the Admiralty under Peel. In the Derby administration of 1858 he was Minister for India, but the publication of a despatch in which he severely rebuked Viscount Canning forced him to resign in order to avert the overthrow of the government. He afterwards took a frequent and influential part in the debates of the Upper House. In 1863 he expressed strongly his sympathies on behalf of Poland, and in 1864 advocated British intervention in favour of Denmark. Ellenborough died without issue, December 2, 1871, when the barony devolved on a nephew, but the earldom and viscounty became extinct. See *History of the Indian Administration of Lord Ellenborough*, by Lord Colchester (1874), who also edited his *Political Diary*, 1828–30 (1881).

Ellery, WILLIAM (1727–1820), born in Newport, Rhode Island, sat in the congress of 1776, and was one of the signers of the Declaration of Independence. From 1790 till his death he retained the office of collector in his native place.

Ellesmere, a town of Shropshire, near a beautiful lake or mere of 120 acres, 19 miles N.N.W.

of Shrewsbury. Pop. 1800. The Ellesmere Canal, connecting the Severn and the Mersey, passes here. It is carried across the Dee and the Vale of Llangollen by Telford's Ellesmere Aqueduct (1805), 1007 feet long and 127 high. ELLESMERE PORT, in Cheshire, is at its junction with the Manchester Ship Canal; pop. with Whitby, 13,000.

Ellesmere, FRANCIS EGERTON, first EARL OF, was second son of the first Duke of Sutherland, and was born in London, 1st January 1800. Educated at Eton and Christ Church, Oxford, he sat for Bletchingley, Sutherland, and South Lancashire, and successively (1828-30) held the offices of Irish Secretary and Secretary for War. In 1833, on succeeding to his father's Bridgewater estates, he assumed the name of Egerton, in lieu of his patronymic Leveson-Gower, and in 1846 became Earl of Ellesmere and Viscount Brackley. He translated *Faust*, published poems, histories, and sketches of travel, and was a patron of the arts. He died 18th February 1857.

Ellesmere Land, an Arctic region west of Smith Sound.

Ellice Islands, N. of Fiji, extend 360 miles from NW. to SE. between 5½° and 11° S. lat. and 176° and 180° E. long. They consist of nine groups of atolls or coral islands, one of which groups was discovered in March 1819 by the American Captain Peyster. Another of the atolls had previously been discovered in 1781. The population of the whole archipelago is about 3500, mostly Christianised Polynesians. Like the people of Samoa and Tonga they have a fine physique, and are peaceable in disposition. The islands grow little but coconut trees, copra being the main export. A little guano also is exported. A British protectorate since 1892, they are now part of the Gilbert and Ellice Islands Colony (1915), and are subject to the jurisdiction of the High Commissioner for the Western Pacific.

Ellichpur, chief town of a former district of the same name (since 1905 part of Amraoti) in the north of Berar, was at one time capital of the Deccan, and is said to have contained 40,000 houses. Its buildings include an extensive palace (fast falling to ruin), a detached fort, the burial shrine of Dalla Ráhmán, and several handsome tombs of the nawábs. The military cantonment of Paratwada is 2 miles distant. Pop. (1881) 26,728; (1921) 26,800.

Ellicott, CHARLES JOHN, Bishop of Gloucester and Bristol, was born 25th April 1819, at Whitwell, near Stamford, of which parish his father was rector. He was educated at Oakham and Stamford schools, and at the university of Cambridge, where he graduated in 1841, and was elected fellow of St John's College. He became rector of Pilton, Rutlandshire, in 1848, professor of Divinity at King's College, London, in 1853, Hulsean lecturer at Cambridge in 1859, and Hulsean professor of Divinity the year after. Dean of Exeter from 1861, he was Bishop of Gloucester and Bristol from 1863 till the sees were separated in 1897, and Bishop of Gloucester till his resignation in 1905. His episcopate was distinguished by the most vigorous and catholic-spirited activity in educational, missionary, and church extension work. Chairman for eleven years of the New Testament Revision Committee, he is best known as a commentator, eminent for the thoroughness of his expository method, having published critical and grammatical commentaries on Galatians (1854), Ephesians (1855), Philippians, Colossians, Thessalonians, Philemon, and the Pastoral Epistles (1861); works on the Sabbath, on Scripture and its Interpretation, and on Modern Scepticism. A useful work which he

edited was *A New Testament Commentary for English Readers* (3 vols.), with another on the *Old Testament* (5 vols.). He died 16th October 1905.

Elliot, JEAN, the author of 'The Flowers of the Forest,' a touching lyric on the disaster of Flodden, was the daughter of Sir Gilbert Elliot of Minto House, Teviotdale, where she was born in 1727. The greater part of her life was spent in Edinburgh (1756-1804). She died at the family seat or at Monteviot, on 29th March 1805. Her eldest brother, Sir Gilbert Elliot (1722-77), was himself a song-writer; whilst John, the third brother, who died in 1808, was a distinguished admiral. See MINTO.

Elliotson, JOHN, an English physician, was born in London in 1791. After leaving Jesus College, Cambridge, he studied medicine at Edinburgh and London, and was for five years assistant physician at Guy's Hospital. In 1831 he became professor of the practice of medicine in the university of London, and took an active share in the establishment of University College Hospital. He was at this time one of the foremost physicians of London, and a successful lecturer. In 1837 he became a convert to mesmerism, which cost him his professorship in 1838, but did not apparently much diminish his private practice. He died in London on 29th July 1868. Besides being one of the first to use the stethoscope, Elliotson conducted numerous useful experiments as to the action of drugs, and did much to encourage the practice of clinical study. He was the founder of the Phrenological Society. His name will live securely from its connection with Thackeray's *Pendennis*.

Elliott, EBENEZER, the Corn-law Rhymer, was born of mixed moss-trooper and yeoman ancestry at the New Foundry, Masbro', in Rotherham parish, Yorkshire, on 17th March 1781. A shy and morbid boy, who proved a dull pupil at four different schools, he worked in his father's foundry from his sixteenth to his twenty-third year, and threatened to become a 'sad drunken dog,' till the picture of a primrose in Sowerby's *Botany* 'led him into the fields, and poetry followed.' His *Vernal Walk*, written at sixteen, was published in 1801; to it succeeded *Night* (1818), *The Village Patriarch* (1829), *Corn-law Rhymes and the Ranter* (3d ed. 1831), and other volumes—collected in 1840 (new ed. 2 vols. 1876). He had married early, and sunk all his wife's fortune in his father's business; but in 1821, with a borrowed capital of £100, he started on his own account as a bar-iron merchant at Sheffield, and thrived exceedingly, 'making £20 a day sometimes without stirring from his counting-house, or ever seeing the goods he disposed of.' Though in 1837 he lost fully one-third of his savings, still in 1841 he was able to retire with good £300 a year to a house of his own building at Great Houghton, near Barnsley. Here he died 1st December 1849.

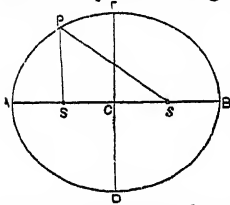

Elliott the poet is well-nigh forgotten. His poems are nowadays little more read than in his lifetime was his tragedy *Taurasdes*. It had three readers, Elliott one of them. But Elliott the Corn-law Rhymer is still remembered as the Tyrtæus of that mighty conflict whose triumph he lived to witness, as the typical maker of ballads, not needing to care who should make the laws of the nation. This Corn-law Rhymer had been bred a 'Berean' and Jacobin; yet he hated Communists, Socialists, and physical-force Chartists; he lies buried in Darfield churchyard; he left two sons Established clergymen. His whole life long he looked on the Corn-laws as the 'cause of all the crime that is committed'; agriculturists, he maintained, 'ought not to live by robbing and murdering the manufacturers.' On the other hand, 'Capital has a

right to rule the world,' and 'competition is the great social law of God.'

There are two poor memoirs of Elliott, by his son-in-law, John Watkins (1850), and by 'January Searle'—i.e. George S. Phillips (1850). See also Carlyle's essay from the *Edinburgh* for July 1832, and Professor Dowden in Ward's *English Poets* (2d ed. 1883).

Ellipse, a section of a cone by a plane less inclined to the base than is a generator, is intermediate to the circle and parabola (see DIRECTRIX). It is of great importance in Astronomy, being the shape of the orbit described by a planet under the action of gravitation. Mathematically, the ellipse is a closed curve, every point of which has the sum of its distances from two fixed points always the same. These two fixed points are called the foci; and the diameter drawn through them is the major axis; the minor axis bisects the major at right angles. The distance of a point on the curve from the focus is less than that from the directrix. The ratio (*eccentricity*) is fixed. The less the eccentricity the nearer the figure approaches to a circle. When the foci coincide the ellipse becomes a circle, and when they are infinitely apart it becomes a parabola. The tangent at any point of the curve is always equally inclined to the two focal distances; and any diameter bisects all the chords which are parallel to the tangents at its extremities.

The Tammel or Elliptic Compass affords the easiest way of drawing an ellipse. It depends on the principle that when a line of fixed length moves so that its extremities are always on two fixed perpendicular lines, a simple practical method is by passing a loop of thread over two pins

stuck in the foci, Ss in the diagram, the length of the loop being equal to SB. If the point of a pencil be put into the loop P, and moved round so as to keep it stretched, the pencil will trace an ellipse AEBD. There are also various ways of approximating to the figure by the use of circular arcs.

The equation to an ellipse (see GEOMETRY, ANALYTICAL), referred to its centre as origin, and to its major and minor axes as rectangular axes, is $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, where a and b are the semi-major and semi-minor axes respectively. From this equation it may be shown, by the integral calculus, that the area of an ellipse is equal to πab ; or is got by multiplying the product of the semi-major and semi-minor axes by 3.1416 . It may also be shown that the length of the circumference of an ellipse is got by multiplying the major axis by the quantity

$$\pi \left\{ 1 - \left(\frac{1}{2} \right)^2 \frac{e^2}{1} - \left(\frac{1.3}{2.4} \right)^2 \frac{e^4}{3} - \left(\frac{1.3.5}{2.4.6} \right)^2 \frac{e^6}{5} - \&c. \right\}$$

to which there is an excellent practical approximation when e is not too large, viz.

$$\frac{\pi}{2} (a + b + \sqrt{2(a^2 + b^2)}). \text{ The eccentricity, } e, \text{ is } \\ = \sqrt{1 - \frac{b^2}{a^2}} \text{ and the ellipticity is the ratio } a - b \text{ to } a.$$

Another approximation, as good or better, under the same limitation, is $\pi \left(\frac{3}{2}(a + b) - \sqrt{ab} \right)$. The latter is due to Mr Hope-Jones.

Ellipsoids are of two kinds, the simpler being those of revolution, produced by an ellipse turning round the major or the minor axis. The surfaces

so generated are known as prolate and oblate spheroids respectively, and that of our globe is an instance of the latter. The ellipsoid proper has three rectangular axes of different lengths, and its section in any direction is an *ellipse*, whereas the spheroids must give a circular section if cut at right angles to the axis of revolution.

Ellis, or (till 1825) SHARPE, ALEXANDER JOHN (1814–90), philologist, was born at Hoxton, and educated at Shrewsbury, Eton, and Trinity College, Cambridge, where he graduated sixth wrangler in 1837. He wrote numberless papers of great learning on mathematical, musical, and philological questions, and did more than any other scholar to advance the scientific study of phonetics, of early English pronunciation, and of existing English dialects. Of his many and valuable books the most important are *Essentials of Phonetics* (1848); *Universal Writing and Printing* (1856); *Early English Pronunciation, with especial reference to Chaucer and Shakespeare* (5 parts, 1869–89); *Practical Hints on the Quantitative Pronunciation of Latin* (1874); and a translation of Helmholtz's *Sensations of Tone* (1875; 2d ed. 1885).

Ellis, GEORGE (1753–1815), English author, was born in London and educated at Westminster school and Trinity College, Cambridge. A contributor to the *Kolliad* (q.v.), he later changed sides, and became one of the founders of the *Anti-Jacobin* (q.v.). Apart from his work in political satire, Ellis was one of the first to arouse interest in Early English literature, and he edited *Specimens of the Early English Poets* (1790), and *Specimens of Early English Metrical Romances* (1805). He also, in 1796, edited Way's translation of select *Fablaux*. He was an intimate friend of Sir Walter Scott.

Ellis, SIR HENRY (1777–1869), antiquary, born in London, was educated at Merchant Taylors' School, and at St John's College, Oxford, of which he became a Fellow. From the staff of the Bodleian he received, in 1800, an appointment at the British Museum, and became principal librarian (1827–56). His *Introduction to Domesday Book* was published in 1833; his *Original Letters Illustrative of English History*, issued in three series, in the years 1824–46; and his invaluable edition of Brand's *Antiquities*, in 1813. He also wrote a *History of the Parish of St Leonard, Shoreditch*, and works on the Townley and Elgin Marbles, and was the chief editor and writer of the English portion of the edition of Dugdale's *Monasticon* (1817–30). His works exhibit much learning and research.

Ellis, HENRY HAVELOCK, was born at Croydon, 2d February 1859. Before completing his medical education at St Thomas's Hospital, London, he went to Australia and taught in New South Wales from 1875 to 1879. Returning to England in 1880 he qualified in medicine, but devoted himself mainly to literary and scientific work. His many writings include *The Criminal* (1890, 4th ed. 1910), and several volumes of *Studies on the Psychology of Sex* (1899, &c.). His *Impressions and Comments* appeared in 1914 (2d series, 1921).

Ellis, WILLIAM, an eminent English missionary, was born in London, 29th August 1794. He was brought up as a gardener, but having offered himself to the London Missionary Society, was trained and despatched in 1816 to the Pacific Islands, where he laboured for nearly ten years, first at Elmeo, next at Oahu. The illness of his wife obliged him to return to England in 1825, and he became foreign secretary to his Society (1832–41). Meantime his *Tour through Hawaii* (1826) and his *Polynesian Researches* (1839) extended his fame as a missionary. His wife died in 1835, and two years later he married Sarah Stickney, in her day a well-known teacher, and author of *The*

Women of England (1838), *The Daughters of England* (1842), *The Wives of England* (1843), *Hearts and Homes* (1848-49), and *The Mothers of Great Men* (1859). From 1847 to 1853 Ellis ministered to a small congregational church at Hodde-don, Hertfordshire. In 1838 he had published a history of Madagascar, and in 1853 he was sent on missionary work to that island. He made four different visits, the last extending over four years (1861-65), and by his tact and sagacity did much to settle the external relations of the Christians on a safe basis. His books on Madagascar, besides their personal and religious interest, became standard works. Ellis died 9th June 1872; his wife but a week later. See the Life by his son (1873).

Ellis Island, a small island in the north of upper New York Bay, owned by the United States government, and used by it since 1892 as an immigration station, the administration of which has from time to time been the subject of criticism.

Elliston, ROBERT WILLIAM, actor, was born in London, the son of a watchmaker, in 1774, and was educated at St Paul's school. In 1791 he ran away from home, and made his first appearance on the stage at Bath, where his Romeo in 1793 lifted him into public favour. In 1796 he appeared at the Haymarket and Covent Garden; and after 1803 he made London his headquarters, though still making occasional essays as a provincial manager. He was a member of the Drury Lane company in 1804-9 and 1812-15; in 1819 he became lessee and manager of the theatre, from which, in 1826, he retired a bankrupt. He afterwards played in the Surrey theatre; but dissipation hastened his death, 8th July 1831. Elliston was the first comedian and one of the first tragedians of his day, and in Leigh Hunt's estimation

wonderful rock-cut temples. Of these there are 34 of a large size, Buddhist, Brahmanical, and Jain. Some are cave-temples proper—i.e. chambers cut out in the interior of the rock—but others are vast buildings hewn out of the solid granite of the hills, having an exterior as well as an interior architecture, and being, in fact, magnificent monoliths. In executing the latter, the process was first to sink a great quadrangular trench or pit, leaving the central mass standing, and then to hew and excavate this mass into a temple. The most beautiful of these objects is the Hindu temple, called the Kailás, dedicated to Siva. At its entrance the traveller passes into a large antechamber adorned by numerous rows of pillars. Thence he ascends a few steps into a great rectangular court, averaging 276 feet in length and 154 in width, in the centre of which stands the temple itself, a vast mass of rock richly hewn and carved. It is supported by four rows of pilasters, with colossal elephants and other animals beneath, and seems suspended in the air. The interior is about 103 feet long, 56 broad, and 17 high, but the entire exterior forms a pyramid 164 feet long, 109 wide, and 100 high, and is overlaid with sculpture. In the great court are numerous ponds, obelisks, colonnades, sphinxes, and on the walls thousands of mythological figures of all kinds, from 10 to 12 feet in height. The interior, and certainly some parts of the exterior, have been plastered over and painted. It is now generally believed that the caves date from the 7th century.

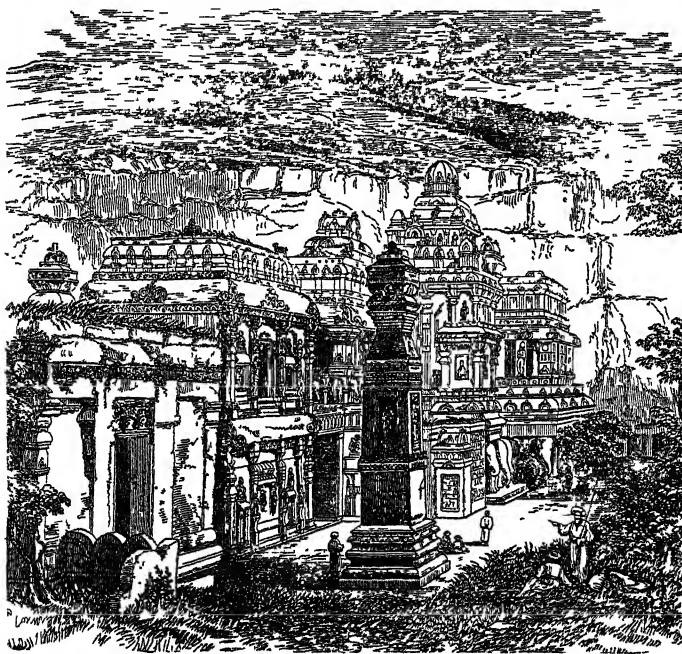

Ellore (*Elvár*), a town in the Kistna district, Madras, on the Jammaler River, 255 miles N. of Madras, with manufactures of woollen carpets and saltpetre. The heat is very oppressive, reaching 110° F. in the shade. Pop. 30,000.

Ellsworth, a city and port of entry in Maine, on the river Union, 28 miles SE. of Bangor, with a very large lumber trade; pop. 3000.

Ellwangen, an industrial town of Württemberg, on the Jagst River, 55 miles N. of Ulm by rail; pop. 5300. The old castle of Hohen-Ellwangen, close to the town, has been used as an agricultural school since 1843.

Ellwood, THOMAS, whose name will never be forgotten from its connection with Milton's, was born at Crowell in Oxfordshire in 1639. At twenty the influence of his friends the Penningtons converted him to Quakerism, from which neither his father's blows, nor confinement within his house, nor frequent imprisonments could cure him. In 1662 he made Milton's acquaintance, and soon visited him 'every day in the afternoon, excepting on the first day of the week, and sitting by [the poet] in his dining-room, read to him in such books in the Latin tongue as he pleased to hear me read.' Milton taught him to read

Latin in the foreign manner. The readings were interrupted six weeks later by Ellwood's illness; but again, in 1665, we find him hiring a cottage at Chalfont St Giles, where Milton might escape the plague then raging in London. One day Milton

The Kailás Temple at Ellora. (From Fergusson.)

the 'best lover on the stage both in tragedy and comedy'; Lamb's eulogy is well known. See the Life by Raymond (2 vols. 1845).

Ellora, a village in the Nizam's dominions, 13 miles NW. of Aurangabad. It is celebrated for its

gave him the manuscript of *Paradise Lost* to read, and when returning it Ellwood said, 'Thou hast said much of "Paradise Lost," but what hast thou to say of "Paradise Found?"' When Milton handed him *Paradise Regained* in London, he added, 'This is owing to you, for you put it into my head by the question you put to me at Chalfont, which before I had not thought of.' Ellwood married in 1669, was busy in controversy, and seems to have had more than his share of the persecutions that fell upon the Quakers almost till his death in 1714. Of his many tracts, treatises, epistles, and even poems, only his Autobiography is now interesting, and that not for his own sake, but because he crossed the orbit of almost our greatest poet. There are editions by Professor Henry Morley in his 'Universal Library' (1885), and by C. G. Crump (1900).

Elm, a village of Switzerland, at the head of a mountain-girt valley in the canton of Glarns, with 1000 inhabitants when, in 1881, the whole of the northern side of Tschingel Peak (10,230 feet) crashed down upon it, destroying a large part of it, and filling the narrow valley with the debris of the landslide.

Elm (*Ulmus*), a genus of trees of the natural order Ulmaceæ, natives of temperate climates, with serrated leaves unequal at the base, and small flowers growing in clusters appearing before the leaves, and containing 4-12 stamens and one germin. The fruit is a samara, or compressed one-seeded little nut, winged all around. Elm is a remarkably variable genus, so much so that botanists are greatly divided in opinion as to which are species and which varieties among the numerous forms comprised in it. There are two well-marked types common to Britain, and having a wide distribution in Europe and Western Asia and Northern Africa. These are the English Elm (*U. campestris*), which is the most common in English woods and pleasure-grounds; and the Scotch or Wych Elm (*U. montana*), which, though more common in Scotland and in Ireland, is more sparingly distributed also in England and on the Continent.

Common English Elm (*Ulmus campestris*):
a, flower; b, fruit.

The English elm often attains a height of from 70 to 90 feet, with a diameter of from 5 to 6 feet, before it is one hundred years old—an age that the elm-tree rarely much outlasts; it may even exceed 100 feet in height. Both species have been productive of many varieties, some of which are so distinct as to be by some considered species and by others as merely well-marked sub-species or varieties. The fact that no reliance can be placed on the progeny of any of these forms,

when reared from seed, having the features and attributes of the parent appears to corroborate the latter view. In consequence of this peculiarity in elm it is necessary, if we wish to perpetuate any specially desirable or meritorious kind, to propagate it by budding, grafting, or layering. Varieties of the English elm are numerous.

All are not alike valuable as timber-trees. For forest planting, seedlings of the type and other well-marked kinds are selected. Besides the typical form, varieties known to nurserymen as the Broad-leaved English Elm (*U. c. latifolia*), the Red English Elm (*U. c. stricta*), and the White English Elm (*U. c. alba*) are preferred to any others as the seed parents, their progeny

Common English Elm
(*Ulmus campestris*).

proving almost invariably valuable timber producers. Of this species there are some interesting and beautiful varieties, much esteemed for their effect in ornamental grounds and garden scenery. The most distinct are the typical form with silver variegated leaves, and also with yellow variegated leaves, and *U. c. viminalis*, of which there is also a silver-leaved form, both of them being remarkable for the small, twiggy character of their shoots, and their light, elegant appearance. The Twisted Elm (*U. c. tortuosa*) is a very singular variety of French origin. Its trunk marked with alternate protuberances and hollows gives it a very remarkable appearance in old trees. Its timber is preferred in France above all others by wheelwrights, particularly for spokes, its fibre being exceedingly tough, twisted, and interlaced together. The Dutch Cork-barked Elm (*U. c. major*) is a well-marked variety or sub-species of the English elm, which was introduced by William III. when the Dutch style of gardening was fashionable. Its rapid growth and adaptability to being clipped into the stiff, formal shapes essential to that style of gardening led to its being much used while the fashion prevailed; but when Dutch gardening disappeared, the cultivation of this variety of elm almost ceased, as its timber is comparatively worthless. The bark of the younger branches is rough and cork-like. The Cork-barked English Elm (*U. c. suberosa*) is a very handsome and well-marked sub-species, growing with greater vigour and to a larger size than the type, having also larger leaves and the bark of the branches distinctly lined with corky wings.

The wood of the English elm is highly valued for its great strength, toughness, and closeness of texture. It is less liable to split than almost any other timber, and powerfully resists the decomposing action of water; it is therefore much in request for keels of ships and boats, masts and spokes of wheels, foundation piles, and wet-planking. The large bosses or knots with which the trunk is frequently covered are much prized in cabinet work and in turnery for their beautiful appearance when cut up

and polished. The bark is used in dyeing and in sugar-refining, and in times of scarcity has been used in Norway for grinding into meal and mixing in bread. The inner bark is used medicinally in cutaneous diseases; it is mucilaginous, and has a bitter astringent taste. In Persia, Italy, and the south of France galls are frequently produced on the leaves, often of large size, containing a clear fluid called *eau d'orme*, which is sweet and viscid, and is used to wash wounds. Towards autumn these galls dry up, leaving a residue of a yellow or blackish balsam called *beaume d'orme*, which was formerly in great repute for diseases of the chest. The seeds of the elm are eagerly eaten by pigeons and common poultry. A peculiar vegetable principle called *ulmin*, or *ulmic acid*, was first discovered in the substance which often spontaneously exudes from the bark of the English elm. It is a dark-brown substance, without smell or taste, insoluble in cold, sparingly soluble in boiling water, which it colours yellowish-brown, and soluble in alcohol and in alkaline solutions.

The typical form of Scotch elm is easily distinguished from the English by its less upright trunk, more spreading branches, and larger, broader leaves. The tree is generally considered more picturesque in style than the English elm. Its timber, though more liable to crack, is quite as much esteemed for its durability and toughness, and is used for nearly every purpose for which that of the English elm is in demand. The enormous bosses which frequently occur on the trunk are highly valued in cabinet-making. The varieties of this species are numerous, and some of them are important both as timber and as ornamental trees. The Smooth-leaved Wych Elm (*U. m. glabra*) is so distinct in its upright growth, smaller and smooth leaves, and other even more important characters, from the typical Wych Elm, that some are disposed to regard it as a species. It is certainly well marked, and from it have sprung the Huntingdon Elm, the Chichester Elm, and the Scampston Elm, all of which have a strong resemblance to each other, and are remarkable for their great rapidity of growth and their value as timber-trees. Of ornamental and curious varieties, the Wych Elm is the parent of several, the more remarkable of which are the Weeping Wych Elm (*U. m. pendula*), the Exeter Wych Elm (*U. m. fastigiata*), and the Variegated Wych Elm (*U. m. variegata*), the leaves of which are silvery striped. *U. effusa* is a continental species with a large spreading head and smooth bark, distinguished also by the long stalks of its flowers and its ciliated fruit.

The American or White Elm (*U. americana*), which abounds in the Mississippi basin, and attains its loftiest stature between 42° and 46° N. lat., is a magnificent tree, sometimes 100 feet in height, the trunk reaching 60 or 70 feet before it separates into branches, and the widely diffused pendulous branches floating gracefully in the air; but the timber is not much esteemed. Slippery Elm (*U. fulva*) is also common in the basin of the Mississippi as far south as 31° N. lat., and in the western parts of Canada. It attains a height of 50 or 60 feet. The wood is more valuable than that of the last species, but much inferior to the English elm. The leaves and bark yield an abundant mucilage, which is bland and demulcent, and esteemed a valuable remedy in catarrh, dysentery, and other complaints. The Wahoo or Winged Elm (*U. alata*) is a small tree, found from 37° N. lat. to Florida, Louisiana, and Arkansas, remarkable for the branches being furnished on two opposite sides with wings of cork. The wood is fine-grained, compact, and heavy. Both the English elm and the Wych elm have been introduced into the United States. *U. chinensis* is a Chinese species of elm,

the leaves of which bear galls used in tanning and dyeing.

The name Spanish Elm is given in the West Indies to a valuable timber-tree also called Bois de Chypre, *Cordia Gerascanthus*, of the natural order Cordiaceæ; also to *Hamelia ventricosa*, of the natural order Rubiaceæ, the timber of which is known to cabinetmakers as Prince-wood.

Elmali, a town of Asia Minor, on the Lycian tableland, 45 miles W. of Adalia. It has manufactures of red leather, dye-works, and a general trade. It is inhabited by direct descendants of the ancient Lycians. Pop. 4000.

Elmina, a British settlement and fortified seaport on the Gold Coast, a few miles W. of Cape Coast Castle. It was first settled by merchants of Dieppe, came into the hands of the Portuguese in 1471, and of the Dutch in 1637, and in 1872 was ceded to the British, who destroyed the native town during the Ashanti war. Pop. 6000.

Elmira, capital of Chemung county, New York, on the Chemung River, 149 miles ESE. of Buffalo by rail. It contains a court-house, a famous state reformatory prison (see PRISONS), and the Elmira Female College, and has extensive manufactures of valves, iron bridges, automobile parts, iron rails, railway and other carriages, &c. Pop. (1870) 15,863; (1910) 37,176; (1920) 45,393.

Elmo's Fire, Sr, is the popular name of an electric appearance sometimes seen, especially in southern climates during thunder-storms, of a brush or star of light at the tops of masts, spires, or other pointed objects. It is also observed at the tops of trees, on the manes of horses, and occasionally about human heads. It is similar in kind to the luminous glow seen at the point when a lightning-rod is working imperfectly, or when there is any very rapid production of electricity (see ELECTRICITY). In the four years 1884-87 eleven cases of St Elmo's fire were recorded at the Ben Nevis observatory. The phenomenon, as seen at sea, was woven by the Greeks into the myth of Castor and Pollux, and was regarded as of friendly omen. The name of *Elmo* is by many thought to be a corruption of that of Helena, the sister of Castor and Pollux. Others take it to be a corruption of St Erasmus, a Syrian bishop and martyr of the 3d century (Italianised, *Ermo*, *Elmo*). The phenomenon has also been called the fire of St Elias, of St Clara, of St Nicolas, and of Helena, as well as *compositæ* or *compositant* (i.e. *corpus sanctum*) on the Suffolk seaboard.

Elmshorn, a town in the Prussian province of Sleswick-Holstein, is situated on a navigable feeder of the Elbe, 20 miles NW. of Hamburg. It has considerable manufactures, especially of boots and shoes, an active trade in grain, a boat-building yard, and some breweries and tanneries. Pop. 15,000.

Elmsley, PETER, classical scholar, was born in 1773, and educated at Westminster and Christ Church, Oxford, where he graduated B.A. in 1794. He next took orders, and was presented in 1798 to the living of Little Horkesley in Essex, which he held till his death. He lived at various periods of his life at Edinburgh, at St Mary Cray in Kent, and at Oxford, where he was in 1823 appointed principal of St Alban Hall, and Camden professor of Ancient History. Here he died, 8th March 1825. Elmsley contributed to the *Edinburgh* and *Quarterly* reviews, but is now remembered only by his valuable critical work on Sophocles and Euripides. See *Elmsleiana Critica* (1833).

El Obeid. See OBEID (EL).

Elocution (Lat., 'speaking out'), the art of effective speaking, more especially of public speaking. It regards solely the utterance or delivery; while the wider art of oratory takes account also

of the matter spoken. The art of elocution held a prominent place in ancient education.

Elodea. See ANACHARIS.

Eloge. When a member of the French Academy dies, it is customary for his successor to deliver an oration, setting forth his merits and services. This is called an *éloge* (Lat. *elogium*, 'a short saying,' confused with Gr. *eulogia*, 'praise'), and a considerable branch of French literature goes by the name. Interesting and valuable collections are the *éloges* of Fontenelle (2 vols. 1731), and of Cuvier (1819).

Elohim. Heb., plural of *Eloah* (only used in poetry; cf. Arab. *Ilāh*, Chald. *Elāh*, Syr. *Alōh*), might, power; in plur., great beings, kings, angels, gods, *Deity*. As a *pluralis excellentie* or *majestatis*, and joined to the singular verb, it denotes, with very rare exceptions, *the One*, true God. Joined to the plural verb, however, it usually means gods in general, whether including the One or not. It is mostly used (in the singular sense) for or together with *Jehovah*; but some portions of the Scriptures employ exclusively either the one term or the other. This circumstance has given rise to endless discussions, and suggested the opinion that Genesis is by different authors (see BIBLE, *JEHOVAH*). It was very probably Peter Lombard who first tried to prove the Trinity out of this plural form—an attempt which, although unanimously and scornfully rejected by almost all scholars, from Calvin, Calixtus, the younger Buxtorf, &c., to our times, was revived by Rudolf Stier.

Eloi, or ELIGIUS, ST, Bishop of Noyon and apostle of Flanders (588–658), was originally a goldsmith, and as such became patron of goldsmiths and hammermen.

Elopement. See MARRIAGE, ABDUCTION, GREYNA GREEN.

Elopura. See BORNEO.

El Paso, capital of El Paso county, Texas, on the left bank of the Rio Grande (which forms the boundary between Mexico and the United States), at the junction of the Southern Pacific with the Mexican railways. There is much transit trade, with some silver-smelting and meat-packing. Pop. (1880) 736; (1890) 10,338; (1900) 15,906; (1910) 39,279; (1920) 77,560. Opposite is the Mexican town of Ciudad Juárez (q.v.), formerly called El Paso del Norte.

Elphege, or ALPHEGE, ST (954–1012), called in his own time *ÆLFHEAH*, or *GODWINE*, was a monk of Deerhurst, an anchorite, afterwards abbot, at Bath; in 984 was made bishop of Winchester by Dunstan's influence, and in 1006 archbishop of Canterbury. He went as Æthelred's ambassador to Olaf Tryggvesson, and confirmed (or possibly converted) him at Andover in 994. When Canterbury was sacked by the Danes in 1011 he was taken prisoner, and refusing to pay ransom, was murdered seven months later.

Elphin, a bishop's see in Roscommon, Ireland, united to Kilmore in 1833.

Elphinstone, ADMIRAL. See KEITH (VISCOUNT).

Elphinstone, MOUNTSTUART, fourth son of the eleventh Lord Elphinstone, was born in 1779, entered the Bengal civil service in 1795, and was posted to Benares, where he laid the foundation of that love of literature which distinguished him through life. During the operations of 1803 he was attached to Wellesley's staff, and his conspicuous services earned from his general the compliment that he had 'mistaken his profession, and ought to have been a soldier,' from his superiors the appointment to the post of resident at Nagpur. In 1808 he was selected as envoy to Shah Shuja (see

AFGHANISTAN), of which the only fruit that remains is his *Account of Cabul* (1815); and in 1810 he became resident at Poona, where, in the Mahratta war of 1817, his military qualifications gained for him the honour of bringing the campaign to an end, and organising the newly-acquired territory. During his governorship of Bombay (1819–27) he founded the present system of administration, and greatly advanced public education. He returned to England in 1829, and declining the governor-generalship of India, lived in comparative retirement until his death, 20th November 1859. Elphinstone ranks next to Wellesley among those most instrumental in raising the fabric of British rule in India after the downfall of the Mahratta power. His well-known *History of India* appeared in 1841 (7th ed. 1889). See his *Life* (1884) by Sir E. Colebrooke, who also edited his *Rise of British Power in the East* (1887); and his *Official Writings*, with Memoir by Forrest (1884).

Elphinstone, WILLIAM, a celebrated Scottish prelate, and founder of King's College, Aberdeen, was born in 1431. He was the son of William Elphinstone, a canon of Glasgow, and archdeacon of Teviotdale—a natural son, for the marriage of ecclesiastics was then prohibited. Elphinstone studied at the university of Glasgow, where he took his degree of M.A. in 1452, some time later receiving priest's orders. He spent some years on the Continent, and so highly distinguished himself in the study of law that he was appointed professor in the university of Paris, and afterwards at Orleans. He returned to Scotland, and was made successively official-general of the diocese of Glasgow (1471–72), rector of the university (1474), and official of Lothian in 1478, 'then probably,' says Mr Cosmo Innes (*Sketches of Early Scottish History*, Edin. 1861), 'the second judicial office in the kingdom.' He was made Bishop of Ross in 1481, and of Aberdeen in 1483; was several times engaged in embassies, and for a few months before the death of James III. held the office of chancellor of the kingdom. Under James IV. he was employed on a mission to the Continent, and seems to have been keeper of the Privy Seal from 1492 till his death. He applied himself to the faithful discharge of his episcopal functions, endeavouring to reform the clergy, the service, and the ritual of the church. It appears to have been chiefly through his influence that the first printing-press—that of Chepman and Millar—was established in Scotland. The college of Aberdeen was founded in 1500, and dedicated to St Mary, a name afterwards changed to King's College. Additions to the cathedral and a stone bridge over the Dee were also due to his energy and liberality. The fatal battle of Flodden, 9th September 1513, broke the spirit of Elphinstone, who was never seen to smile after. He died in Edinburgh, 25th October 1514, and was buried before the high altar of the chapel of King's College which he had founded. His *Breviarium Aberdonense*, printed in 1509–10, was reprinted in two volumes quarto at London in 1833.

Elsass-Lothringen. See ALSACE-LORRAINE.

Elsinore (Dan. *Helsingør*), a town and seaport of Denmark, on the island of Zealand, is situated on the western shore of the Sound, and at its narrowest part, 2½ miles nearly due west of Helsingborg in Sweden, and 37 by rail N. of Copenhagen. The town, which has been in recent times considerably improved, consists of one principal street, with several lateral branches. The harbour (enlarged in 1833–84) has 22 to 26 feet of water, and the roadstead outside affords excellent anchorage. Elsinore has considerable trade, and some ship-building. Pop. 17,000. The Sound dues were collected here until their abolition in 1857.

Saxo Grammaticus, a famous writer of the 12th century, was born at Elsinore, and here too Shakespeare lays the scene of *Hamlet*. Elsinore was raised to the rank of a town in 1416; it was several times destroyed by the Hanseatic League, and in 1658 was taken by the Swedes, but restored to Denmark two years later. A short distance east of the town is the fortified castle of Kronborg, built in the Dutch Renaissance style by Frederick II. in 1580, while to the north-west of Elsinore stands the royal castle of Marienlyst, now much visited as a seaside resort; it commands an extensive view of the Sound and its islands, its shores, and the towns on them.

Elssler, the name of two celebrated dancers, sisters, and natives of Vienna—Therese (1808-78) and Fanny (1810-84). Their first great triumph was at Berlin in 1830; in 1841, after a tour through the capitals of Europe, the two sisters went to America, where they excited unwonted enthusiasm. They retired from the stage in 1851, in which year Therese became the wife of Prince Adalbert of Prussia, and was ennobled by the king of Prussia as Frau von Barnim.

Elster, the name of two rivers of Germany, the White and the Black Elster. The White Elster rises at the foot of the Elster Mountains, on the north-western boundary of Bohemia, flows in a northerly direction, and falls into the Saale, above the town of Halle, in Prussian Saxony. Total length, 122 miles. The Black Elster rises in Saxony, south of Elstra, flows north-west, and joins the Elbe 9 miles S.E. of Wittenberg, after a course of 112 miles.

Elster, a Spa of Saxony, on the Bohemian frontier, 20 miles S. of Plauen; resident pop. 2000.

Elstracke, RENOLO, long classed as one of the earliest native English engravers, was born probably in Belgium towards the end of the 16th century, and flourished in England in the early part of the following century. He worked chiefly for the booksellers, and his engravings, including portraits of the kings of England, of Mary, Queen of Scots, and Darnley, of Whittington, and numerous other notabilities, are much sought after, chiefly from their rarity.

Elswick, a district in the western outskirts of Newcastle. Here are located the works of the firm of Sir W. G. Armstrong, Whitworth, & Co. (see ARMSTRONG, LORD), which are among the largest of the kind in Europe. The engineering section of these works dates from 1847; the ordnance-works were founded in 1857. Elswick Park, including Elswick Hall, was opened as a recreation-ground in 1878. Elswick forms three wards of the county borough of Newcastle-on-Tyne.

El Teb. See TEB (EL)

Eltham, the seat formerly of a royal palace in the west of Kent, now part of the metropolitan borough of Woolwich (q.v.).

Elton, or YELTON, a shallow salt lake of Russia, with an area of 62 sq. m., is near the north-east frontier of the government of Astrakhan. In spring the lake has a layer of almost pure salt-crystals, from 2 to 4½ inches thick. The yield forms a large proportion of the total salt production of Russia.

Elton, CHARLES ISAAC (1839-1900), of White-staunton, Somerset, an eminent jurist and ethnologist, was maternal grandson of Sir Charles Abraham Elton (1778-1853), of Clevedon Court, Somerset, poet and translator of Hesiod. He had his education at Cheltenham and Balliol College, Oxford, became fellow of Queen's College in 1862, was called to the bar at Lincoln's Inn in 1865, and afterwards became Q.C. He was Conservative member of parliament for West Somerset in

1884-85, and in 1886-92. He had already made a reputation as a jurist by his books, *The Tenures of Kent* (1867), *A Treatise on Commons and Waste Lands* (1868), *A Treatise on Copyholds and Customary Tenures of Land* (1874), and *Custom and Tenant Right* (1882), when he placed himself in the front rank of English ethnologists by his *Origins of English History* (1882). Not the least merit of this learned and ably reasoned work is its vindication of the Celtic element in the English race, which had been unduly belittled by the predominant Teutonic school of English history. The dissertation on *Borough English* (q.v.) is a masterpiece of learning and lucidity. *William Shakespeare, his Family and Friends*, appeared in 1904.

Elutriation is the term applied to the process of separating, by means of water, the finer particles of earths and pigments from the heavier portions. The apparatus generally used is a large vat, in which grinding wheels revolve; and the substance to be reduced to powder being placed in the vat along with water, the wheels in revolving not only pulverise the material, but from their motion being communicated to the water the latter is enabled to retain in mechanical suspension the finer particles of the clay, &c. By allowing a stream of water to flow in and out of the vat, the finer particles can be constantly floated away, and the liquid being run into settling vats, the fine powder settles to the bottom, when the water can be run off from the surface. This process is much employed in the manufacture of the materials used in pottery, and in the preparation of pigments.

Elvan, or ELVANITE, is the miner's name in the south-west of England for a granular crystalline rock, composed of quartz and orthoclase, which forms veins associated with granite. It occurs as veins not only proceeding from the granite and traversing other rocks, but in the body of the granite itself. It is included by geologists under Quartz-porphry.

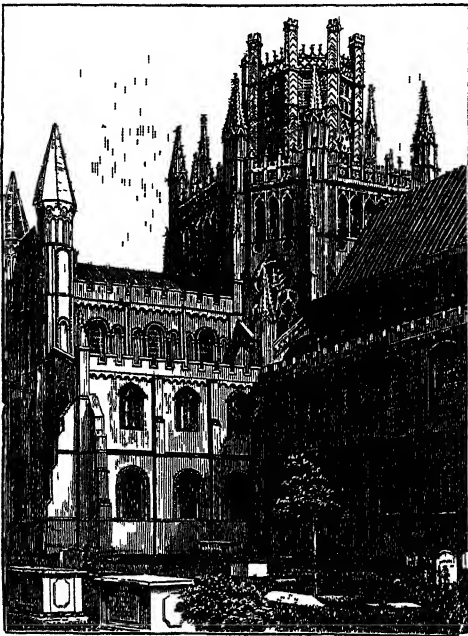

Elvas, the strongest fortified city of Portugal, in the province of Alemtejo, near the Spanish frontier, and 10 miles W. of Badajoz by rail. Standing upon a hill, it is defended by seven large bastions and two isolated forts, and has an arsenal and cannon-foundry. It is a gloomy town and a dirty, yet is supplied with water by a fine aqueduct, carried on three rows of superimposed arches. Its inhabitants (12,000) carry on an active contraband trade with Spain, principally in British manufactured wares, also in wool and wine. The district, which is very fertile, yields oil, wine, fruits, and vegetables. Elvas was made a bishop's see in 1570. In 1580 it was taken by the Spaniards, but they suffered a severe reverse before the town in 1659, and laid siege to it in vain in 1711. It was captured again in 1808 by the French.

Elves. See FAIRIES.

Elwes, JOHN, M.P., a famous miser, born in 1714, was the son of a successful brewer in Southwark named Meggot. With some good qualities of mind, he was so overcome by the passion of avarice that he would walk miles in the rain to save the hire of a conveyance, would sit for hours in wet clothes to save the expense of a fire, or risk his life to save paying a penny at a turnpike. His only indulgence seems to have been hunting. He died at Marcham, Berkshire, 26th November 1789, leaving property worth half a million.

Ely, a city of Cambridgeshire, crowns a low eminence on the left bank of the Ouse, amid the fen-land, 16 miles N.N.E. of Cambridge, and 30 S.E. of Peterborough. Here, in 673, St Etheldreda (q.v.) founded a mixed monastery, which, burned in 870 by the Danes, was refounded in 970 as a Bene-

dictine abbey by Ethelwold, Bishop of Winchester. That abbey a century later became Helward's 'camp of refuge,' until, in 1071, after a long and obstinate defence, Abbot Thurstan had to surrender to the Conqueror. In 1083 the first Norman abbot laid the foundation of the present church, which was made a cathedral in 1109, and which, as we see it to-day, is one of the most glorious shrines in Christendom. A cruciform structure, 537 feet long by 179 feet across the great transepts, it offers examples of all styles of Gothic, from early Norman to late Perpendicular, and is a growth of more than four centuries. There is the Early English 'galilee' or western porch (circa 1200); the western tower, 225 feet high, Transition Norman and Decorated (1174-1382); the south-west transept, now the baptistery; the late Norman nave (1150-89), 208 by 78 feet, with modern painted ceiling; the great transepts (1083-1170), Norman, with Perpendicular insertions; the richly sculptured choir (1234-1533), Early English, Decorated, and Perpendicular; the Decorated north-eastern Lady Chapel (1321-49); and at the crossing, the exquisite Decorated 'octagon' and lantern (1322-42), built by Alan de Walsingham on the fall of the great central tower. This, 'the only Gothic dome in existence,' rises to a height of 170 feet. Since 1845 the whole pile has been ably restored, mainly under the supervision of the late Sir G. G. Scott.

Ely Cathedral—Octagon.

It wants the north-west transept, the cloisters, and the chapter-house; but the 13th century Guesten Hall is now the deanery, and the 'Ely Porta,' or great gateway (1380), houses a grammar-school founded by Henry VIII. in 1541. The Bishop's Palace is a fine brick Tudor building. Among the bishops, nearly sixty in number, have been Langham, Bourchier, and Morton (archbishops of Canterbury), Arundel (archbishop of York), and Andrewes, Wren, Patrick, and Harold Browne. Of great laymen also, Ely has its memories, from Canute to Cromwell, who lived here 1636-40. There is a weekly market; and oil, earthenware, and clay-pipes are manufactured. Pop. 8000.—The 'Isle' of

Ely, for which see the articles CAMBRIDGESHIRE and BEDFORD LEVILL, contains also March and Wisbeach, and is 372 sq. m. in area, with 74,000 inhabitants. Till 1837 a county palatine, it is still a parliamentary and administrative county.

See Benthams', *History of Ely Cathedral* (2d ed. 1812); J. H. Clement's *History of Ely* (1868); Canon D. J. Stewart's *Architectural History of Ely Cathedral* (1868); Dean Merivale's *Bissexcentenary Festival of St Etheldreda* (1874); and Murray's *Eastern Cathedrals*.

Elyot, SIR THOMAS, author of *The Governour*, seems to have been born not later than 1490, in Wiltshire (not Suffolk), and not to have studied at either Oxford or Cambridge. In 1511 he became clerk of assize on the western circuit, in 1523 clerk of the king's council. In a letter addressed to Cromwell he complains that he performed the duties of this clerkship by the space of six years and a half 'without fee, without reward more than the ordinarie, and that which more grieveth me, without thank of the king.' Later letters reveal him to us much impoverished by lawsuits, and begging for a share in the confiscated property of the monasteries. In 1531-32, as ambassador to Charles V., he visited the Low Countries and Germany, having orders to procure, if possible, the arrest of Tyndale. In 1535 he went on a second embassy to the emperor, whom he seems to have followed from Barcelona to Tunis and Naples. Member for Cambridge in 1542, he died at Carlton, Cambridgeshire, 20th March 1546. His chief work, *The Boke named the Governour, devised by Sir Thomas Elyot, Knight*, was published in 1531. It may be described as the earliest treatise on moral philosophy in the English language, the author's principal object being 'to instruct men in such virtues as shall be expedient for them which shall have authoritie in a weale publike.' An elaborate tenth edition appeared in two vols. in 1880, with an excellent life, notes, and glossary by Mr H. H. S. Croft. Elyot's twelve other works include *Of the Knowledge which maketh a Wise Man* (1533); *Pasquil the Playme* (1533); *Isocrates' Doctrinal of Princes* (1534); *Picus de Mirandola's Rules of a Christian Lyffe* (1534); *The Castel of Helth* (1534); *The Bankette of Sapience* (1534); *Bibliotheca* (1538), the first Latin-English dictionary; *The Image of Governance* (1540); *Defence of Good Women* (1545); and *Preservative against Deth* (1545). These books went through edition after edition in their author's lifetime, and they have now become among the rarest treasures of the bibliomaniac.

Elysium (Gr. *elysion*), a place in the infernal regions of the ancient classical mythology, where the souls of the good dwell after death. In the *Odyssey*, Homer describes it as a place where the souls of the departed lived in ease and abundance among innocent pleasures, enjoying a mild and wholesome air. In the *Iliad*, however, he gives a sombre view of the state of the departed souls. Achilles, though in Elysium, is made to envy the life of the meanest hind on earth. By succeeding poets the bliss of Elysium is drawn in much brighter colours. Besides the amenity and various delights of the place, diverse employments are found for the inhabitants, according to the ruling passion of each while on earth. The Elysian plains were supposed by some writers to be in mid-air, by others in the sun, by others in the centre of the earth, next to Tartarus, and by others in the Islands of the Blest. See HADES.

Elytra, or WING-COVERS, a term applied to the fore-wings of beetles (Coleoptera), which are modified to form more or less tough and hard coverings for the hind pair. The term Hemelytra is applied to the short, firm fore-wings of earwigs (q.v.) (Dermaptera). See INSECTS, BEETLES.

Elze, FRIEDRICH KARL, Shakespearian scholar, was born at Dessau, May 22, 1821, studied at Leipzig and Berlin, devoting especial attention to English literature, and afterwards continued his studies in England and Scotland. In 1875 he was appointed to the newly-established chair of English Language and Literature at Halle, and here he died January 21, 1889. His early publications include a collection of English songs, and *Atlantis* (1853-54), a journal dealing with England and America. In editions of *Hamlet*, Chapman's *Alphonsus*, and Rowley's *When you see me, you know me*—the last two edited for the first time—he endeavoured to apply the strict method of classical philology to a modern language. An English translation of his biography of Byron appeared in 1872, and of his *Essays on Shakespeare* in 1874; these last are selected from the *Shakespeare-Jahrbuch*, which he edited for the German Shakespeare Society from 1868 to 1879. Other works are his *William Shakespeare* (Halle, 1876; Eng. trans. 1888), his *Notes on Elizabethan Dramatists* (Halle, 2 vols. 1880-84), and his *Grundriss der englischen Philologie* (1887). Elze was a labious student and sagacious critic rather than a mere antiquary or collector.

Elzevir, or ELSEVIER, a celebrated family of printers at Amsterdam, Leyden, and other places in Holland, whose beautiful editions were chiefly published between the years 1592 and 1681. During this period, covering scarcely a century, M. Willems has catalogued no fewer than 1600 works, all such as were doubtful having been rigorously excluded. The difficulty of determining what are genuine Elzevirs depends partly on there having been a good number of printers who bore the name, and on their having had three or four principal places of business. But above all, they were booksellers as well as printers, hence many works were attributed to them which were hardly published, and certainly not printed, by them; while imitations were constantly being made, and they themselves issued many books under pseudonyms, or other printers' or publishers' names. Louis, the first to make the name famous, is said to have been born at Louvain about the year 1540, and, driven by the religious commotions of the time, to have settled as a bookbinder and bookseller in Leyden, where he died about 1617. The first work issued by him bears the title *Drusii Ebraicorum Questionum ac Responsionum Libri Duo*, and the date 1583. The first work, however, really published by him at his own risk, was a *Eutropius* by P. Merula (1592). From this time till his death he published over a hundred books, his typographical mark (first used in 1595) being the arms of the United Provinces—an eagle on a column, holding in its talons a sheaf of seven arrows, with the inscription *Concordia res parvæ crescunt*.

Five out of Louis's seven sons continued to carry on their father's business. Their names were Matthias, Louis, Ægidius (Giles), Jodocus (Joost), and Bonaventura. The last, in conjunction with his nephew Abraham Elzevir (a son of Matthias), prepared the smaller editions of the Latin classics, in 12mo and 16mo, which are still valued for their beauty and correctness. Among the finest examples of these are the *Livy*, *Tacitus*, *Pliny*, and *Cæsar* (1634-36). Equally celebrated were their 24mo editions of French historical and political authors under the name of the *Petites Républiques*, and their 12mo French and Italian classics. The handiness and cheapness of these duodecimos, of which a volume of no less than 500 pages was sold for but one florin, found approbation from all but a few pedants who believed there could be no scholarship save in folios. The printing was long supervised

by Abiahah, while Bonaventura managed the publication and sale; the learned David Heinsius wrote the Latin introductions and dedications to many of the books. In 1625 they acquired the printing business established at Leyden by Isaac, the second son of Matthias, who had become printer to the university there. His typographical mark was an elm surrounded by a vine-branch bearing clusters of fruit, below which stands a solitary figure, with the motto *Non solus*. M. Willems has proved that the Elzevir type designs were due to Cornelius van Dyck. The two heads of the house died near each other in 1652, and their successors were Joannes Elzevir, Abiahah's son, and Daniel, Bonaventura's son, who nobly maintained the traditions of the press. Their finest works were an *Imitatio* without date, and a psalter of 1653. In 1654 Daniel settled at Amsterdam, where he united with Louis, eldest son of Joost, who had already settled there in 1638, and distinguished himself by his editions of the works of Cartesius. The masterpieces of the new partnership were the *Corpus Juris* in folio (1663) and the French Bible (1669). Their typographical mark was a Minerva with the ægis, an owl, and olive-branch, and the motto *Ne extra oleas*. The last representatives of the house were Peter, grandson of Joost, who flourished at Utrecht from 1670 to 1672, and Abraham, son of the first Abraham, who was university printer at Leyden from 1681 to 1712. The Elzevirs were clever men of business, and were none too liberal to many of the scholars on whose labours they rose to wealth.

Emanation, in Theology and Philosophy, is an important word in various systems which considered all things as *emanating* or *flowing* from a Supreme Principle. According to these, the origin of things is only an overflowing of the divine fullness—an outstreaming of the light from the necessity of its nature, and not any conscious exercise of will on the part of God. What is thus given off as a copy from original perfection departs more and more from its source, and gradually degenerates, which was thought to account for the origin of evil. This doctrine pervades ancient Egyptian and Indian mythology, Neoplatonism (q.v.), and Christian Gnosticism (q.v.). See also RADIUM.

Emancipation, in the Roman law, was the act by which the *Patria Potestas*, or paternal authority, was dissolved in the lifetime of the father. It took place in the form of a sale (*mancipatio*) by the father of the son to a third party, who manumitted him. The Twelve Tables required that this ceremony should be gone through three times, and it was only after the third sale that the son became *sui juris*, under his own law. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a Patron (q.v.), which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren one sale was sufficient. In the law of Scotland, emancipation is called *Forsfamiliation*. See also FAMILY, SLAVERY, CATHOLIC EMANCIPATION.

Emanuel I., king of Portugal, styled THE GREAT, or THE FORTUNATE, was born 31st May 1469, and succeeded John II. in 1495. His reign has been termed the golden age of Portugal. He prepared the code of laws which bears his name, and made his court a centre of chivalry, of art, and of science. Vasco da Gama's voyage round the Cape of Good Hope, Cabral's discovery of Brazil, and the expeditions under Albuquerque and others that extended the Portuguese possessions as far as the Moluccas, were all commissioned and encouraged by Emanuel. Through his exertions Portugal became the first naval power of Europe

and the centre of the commerce of the world. He died 13th December 1521.

Emarginate. See LEAF.

Emba, or **YEMBA**, a river in the Kirghiz territory (or republic), rises at the western base of the Mugalsai Mountains, and flowing south-west, enters the north-east corner of the Caspian Sea after a course of about 450 miles.

Embalming (so named from the balm or balsam often employed), the art of preserving the body after death. In Egypt bodies so preserved are known by the name of mummies, and are called in the hieroglyphs *sahu*, and by St Augustine *galbaroe*. The custom is to be found in many parts of the world, but in all the nature of the technique employed emphasises an Egyptian origin. From Egypt, it is held by Professor Elliot Smith and his school, the practice spread to the Mediterranean littoral, Europe, and the Canary Islands; to East Africa, Upper Congo, Southern Nigeria; to the Persian Gulf, India, Ceylon, Burma, the Malay Archipelago, New Guinea, the islands of the Torres Straits, and thence to Australia, emigrants from the Malay Archipelago carrying it to Tonga, New Zealand, Tahiti, and eventually to the Peruvian coast. The art of embalming seems to have derived its origin from the idea that the preservation of the body was necessary for the return of the soul to the human form after it had completed its cycle of existence of three or ten thousand years. Sanitary reasons may also have influenced the ancient Egyptians; and the legend of Osiris, whose body, destroyed by Typhon, was found by Isis, and embalmed by his son Anubis, gave a religious sanction to the rite. The beginning of the art is at least as old as the 2d dynasty. The bodies of Cleopas, Mycerinus, and others of the age of the 4th dynasty were embalmed. One of the earliest

Egyptian Mummy.

embalments recorded in literature is that of the patriarch Jacob; and the body of Joseph was thus prepared, and transported out of Egypt. The process has been described by Herodotus and Diodorus; but their accounts are only partially confirmed by an examination of the mummies. A scribe marked with a reed-pen a line on the left side beneath the ribs, down which line the *parasclistes*, or ripper of the district (an officer of low class), made a deep incision with a rude knife of stone; he was then pelted with stones, and pursued with curses. The *taricheutes*, or salter, next proceeded to remove the entrails and lungs, with the exception of the heart and kidneys, while a colleague extracted the brain through the nose. The body was ready for the salts and spices necessary for its preservation, the quality of which depended upon the sum to be expended. When Herodotus visited Egypt, three methods prevailed: the first, accessible only to the wealthy, consisted in passing peculiar drugs through the nostrils into the cavities of the skull, rinsing the belly in palm-wine, and filling it with myrrh, cassia, and other substances, and stitching up the incision in the left flank. The mummy was then pickled in natron for seventy days, and then washed and elaborately bandaged up in rolls of linen, cemented by gums, and set upright in a wooden coffin against the walls of the house or tomb. This process cost a silver talent, perhaps equal to £725 of our money. A cheaper process, by means of an injection of cedar-oil, cost a *mina*,

relatively worth about £243. The poorer classes washed the corpse in myrrh, and salted it for seventy days. When thus prepared, and covered with a pictorial representation of the deceased, attired as a labourer in the world to come, and duly labelled as a 'justified Osiris,' the mummy was placed in a costly coffin (see **SARCOPHAGUS**) ready for sepulture, but was frequently kept some time before being buried—often at home—and even produced at festive entertainments, to recall to the guests the transient lot of humanity. All classes were embalmed, even malefactors; but various methods were employed besides those mentioned by Herodotus. Some mummies are found merely dried in the sand; others salted by natron, or soaked in bitumen (Jew's pitch) with or without the flank incision, having the brains removed through the eyes or base of the cranium, with the viscera returned into the body, placed upon it, or deposited in jars in shapes of the genii of the dead, the skin partially gilded, the flank incision covered with a tin plate, the fingers cased in silver, the eyes removed and replaced. So effectual were some of these processes that after 2000 or 3000 years the soles of the feet are still elastic and soft to the touch. The sacred animals were also mummied, but by simpler processes than men. It has been computed that since the practice began in 4000 B.C., down to 700 A.D., when it practically ceased, probably as many as 730,000,000 bodies were embalmed in Egypt; of which many millions are yet concealed. Important finds are made from time to time, as in 1881, when upwards of thirty mummies of potentates, including that of Rameses II., were discovered together at Deir-el-Bahari. Mummies, it may be observed in passing, were used in the 15th and 16th centuries of the Christian era for drugs and other medical purposes, and as nostrums against diseases, and a peculiar brown colour, used as the background of pictures, was obtained from the bitumen.

Despite a general correspondence in methods of embalming, the medicaments employed do not always correspond; the Persians employed wax; the Assyrians, honey; the Jews, aloes and spices; Alexander the Great was preserved in wax and honey, and some Roman bodies have been found thus embalmed. In Burma the bodies of priests were stuffed with spices and honey, and coated with wax and gold-leaf. The art of embalming was probably never wholly lost in Europe; De Bils, Swammerdam, Clauderus, Gooch, Bell, and others attained great success in the art; and a mode of embalming by incisions all over the body is detailed by Penicher. Ruysch, and after him William Hunter, injected essential oils through the principal arteries into the body. Boudet embalmed the bodies with camphor, balsam of Peru, Jew's pitch, tan, and salt. The discovery of Chaussier of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard, and grayish, introduced a new means of embalming by Beclard and Larrey; but owing to the desiccation, the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Gannal in 1834, and of

Mummy Case of Queen Ahmes Nofretari: Height 9 feet. (From Maspero's *L'Archéologie Egyptienne*)

that of arsenic by Tranchini, were followed by the use of chloride of zinc. Salt, alum, potash, arsenious acid, glyceine, methyl alcohol, and several alkalis are the essentials in some methods. Sir B. W. Richardson embalmed bodies by injection through the main arteries. See HEART-BURIAL.

See Pettigrew, *History of Mummies* (1834); Gannal, *Traité d'Embaumement* (1838); Magnus, *Das Embal-samiren* (1839); Richardson, *The Asclepiad* (1888), Wallis Budge, *The Mummy* (1893); Elliot Smith, *Mum-mification in Egypt* (1907); *Migrations of Early Culture* (1915); and (with Dawson) *Egyptian Mummies* (1924); Garstang, *Burial Customs of Ancient Egypt* (1908).

Embankments, in Engineering, are masses of earth, rock, or other materials artificially formed, and rising above the natural surface of the ground. They are chiefly formed either (1) to carry railways, common roads, canals, &c. over depressions of the country; or (2) for hydraulic purposes, such as the formation of reservoirs for storing water, or as defences against the overflowing of rivers and the encroachments of the sea or of lakes.

In the formation of canals, railways, and other roads, embankment and excavation go hand in hand, and, under the name of Earthwork, form—especially in modern times, and since the develop-ment of the railway-system—a vast branch of industry, giving employment to many thousands of labourers, known in England as 'navvies.' See CANAL, DYKE, ROAD, RAILWAY, WATER.

Embargo (from the Spanish *embargar*, 'to in-bar,' 'to arrest') is a temporary order from the Admiralty to prevent the arrival or departure of ships. It may apply to vessels and goods, or to specified goods only; it may be general or special; it may apply to the entering only, to the departure only, or to both entering and departure of ships from particular ports; and lastly, although issued by the Admiralty in England, it would be equally an embargo if issued by any other competent authority. Such embargoes are generally connected in some way or other with a state of war between two countries.

Embassy, in its stricter sense, is a mission pre-sented over by an ambassador, as distinguished from a mission or legation intrusted to an envoy, or other inferior diplomatic minister. See AMBASSADOR.

Ember Days, in the Roman and Anglican churches, are three days appointed four times in the year to be observed as days of fasting and abstinence; being the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the feast of Pentecost, after the 14th September, and after the 13th December. The name is probably derived from the Saxon *ymb*, 'about,' and *ryne*, a 'course' or 'running,' and applied to these fasts because they came round at certain set seasons in the year. In the breviary and missal these days, as recurring in each quarter of the year, are called *quatuor tempora* (the canonists' *jejunia quatuor temporum*, or 'fasts of the four seasons'); and another derivation would make the term only a corruption of this title, perhaps through the German form, *quatember*. The ember days date from an early period in the church's history, and were introduced into England by Augustine. Originally they were only in part devoted to beseeching the grace of the Holy Ghost, as periods when ministers were admitted to holy orders; but it is to this purpose that the ember days are now particularly devoted, Roman Catholic clergy being ordained only on the Saturdays of the ember weeks, while the whole church fasts and prays, and a generally similar usage prevailing in the Church of England, which has appointed special prayers for use at these seasons.

Ember Goose. See DIVER.

Emberiza. See BUNTING.

Embezzlement, the felonious appropriation by clerks, servants, or others in a position of trust, of goods, money, or other chattels intrusted to their care, or received in the course of their duty, on account of their employers. It is essential to the crime of embezzlement that the article taken should not have been in the actual or constructive possession of the employer; for if it were, the offence would amount to larceny (see THEFT). Embezzlement is not a felony at common law; hence persons guilty of this crime sometimes escaped punishment. In consequence of a flagrant instance of this immunity, the Act 39 Geo. III. chap. 85, was passed, whereby embezzlement was made a felony. This act has been repealed, but the law has since been fixed by subsequent enact-ments, and is now included in the Act 24 and 25 Vict. chap. 96.

Embezzlement by clerks or servants is punish-able by penal servitude or imprisonment. If the offender be a male under sixteen, he may also be ordered to be privately whipped, at the discretion of the judge. Questions of much nicety often arose as to whether the facts proved constituted the crime of embezzlement or that of larceny; but this distinction has ceased to be of any importance under recent acts, whereby it is made competent, on an indictment for embezzle-ment, to convict a man of larceny, and *vice versé*. And hence, whichever of the two offences is charged against the servant, if the evidence shows he committed the other offence, then he may be found guilty of that other offence, and punished accordingly.

Embezzlement by bankers, brokers, factors, and other agents is now regulated by the statute cited above. Almost every conceivable species of fraud-ulent misappropriation by bankers and others is now a punishable offence. In particular, by the latter statute, embezzlement by a Bailee (see BAIL-MENT) is now indictable. A shopkeeper, for ex-ample, appropriating goods intrusted for repair, may be tried and convicted (see also FRAUD).

Embezzlement by bankrupts, or rather the pawn-ing or disposing within four months before the bankruptcy of goods or any kind of property obtained on credit, is punishable by two years' imprisonment. See BANKRUPTCY.

Embezzlement of letters and newspapers by ser-vants of the Post-office is also made highly penal by 7 Will. IV. and 1 Vict. chap. 36. The embezzle-ment of newspapers is punishable by fine or im-prisonment; for embezzling a letter the extreme penalty is penal servitude for seven years, or (if the letter contain money or valuables) for life.

Embezzlement of the King's stores is punishable by penal servitude for fourteen years. In regard to this species of embezzlement, summary authority was given to comptrollers and other officers named, on proof of embezzlement of government stores below the value of twenty shillings, to fine the offenders to the amount of double the value of the article taken.

The American law is, in principle, the same as the English, but it seems that a person indicted for larceny cannot be convicted of embezzlement, or *vice versé*. Embezzlement of national property is punishable by the law of the United States; other forms of embezzlement and fraudulent breach of trust are dealt with by the laws of the several states.

In Scotland, the crime of embezzlement, or breach of trust, is punishable at common law. The dis-tinction between this crime and that of theft is substantially the same as between embezzlement and larceny in England. In both countries, the criterion relied upon to distinguish these crimes is

the question of possession by the owner; but in Scotland the security of the decisions of late years has been to a large extent the appropriation of articles entrusted for a temporary purpose as amounting to theft. Until the Scotch law of Scotland agrees with that of England in regard to embezzlement by a bailee.

Emblem. By many writers on this subject symbols and emblems are regarded as almost convertible terms, and hence the former is often used in a sense synonymous with the latter. But, according to Charles de Mignault, the famous commentator on the emblems of Andreas Alciatus, in his tract 'Co-œquation y Symbols, Coats of Arms, and Emblems,' there is a clear distinction between emblems and symbols, which, as he says, 'many persons really and ignorantly confound together.' This writer maintains that 'the force of the emblem depends upon the class of symbol, but they differ as man and animal; the distinguishing being, that as all men are animals, but not all animals are not men, so all emblems are symbols, but all symbols are not emblems.' He also argues the two possess affinity but not identity, they have no absolute convertibility of the one for the other (H. Green, *Shakespeare and the Emblem Writers*, 1-3). But for all practical purposes there is little difference between the two classes. Of the many definitions given of an emblem may be quoted that of Francis Quarles, who says, 'an emblem is but a silent parable; and Cowley describes it as 'a picture and short poem,' expressing some particular concept.' For a complete list of emblems, see BOOK.

Emblem. *Emblem.* growing crops of cereal and vegetable products raised by the labour of the cultivator. — Limit is of trees growing on the land, and grass, and some other emblems. See LANDLORD AND TENANT, *Emblem.*

Emblem. *Emblem.* (Myrobalani emblece), the acid, as a source of fruit of the Indian euphorbiaceous tree *Platyphragma emblece*, is a source of tannin.

Emblem. See ARTICLES, PATERNOSTER.

Embossing. When a raised pattern is produced by means of a pressure upon sheet-metal, leather, cloth, paper, gutta-percha, &c., it is said to be embossed. A vase or dish formed of thin sheet-metal is sometimes decorated in relief by beating it up on the inner or under side. This operation is called beating up, bossing, or *repoussé*, and may be considered as an example of embossing by hand. A similar result is obtained by the use of a hand and counter-die worked in a screw-press or by a falling weight, but this is usually called *stamping* (see DIE-SINKING, and STAMPING, *Emblem.*). The term embossing is not applicable to decoration in relief produced by carving or chiselling out by casting. Writing-paper and card are embossed with a steel die, the counter-die being formed of millboard or leather, faced with gutta-percha. The paper or card is damped, and a fly-press or screw-press is generally used.

Leathers are embossed in several ways. For book-covers, even in the case of patterns in comparatively bold relief, the same tools used for photographic albums, known as *stamping* or *millboard counter-dies* are used along with a lever or screw-press (see BOOK-BINDING). For other purposes the ornament is to be in high relief, moulds or reverses of metal or wood are employed, or separate ornaments of wood or paper are made, fixed to a board, may be used. The leather is first softened with water, and then pressed with the tools of various kinds into the moulds, or stamped over the fixed ornaments, and worked into all their cavities with the fingers and a pointed tool. The hollows of the more deeply relieved portions are filled in with paper pulp and other substances.

At the present time, imitations of embossed leather for wall-decoration are very much in fashion. These are made of canvas, leather, paper, and various other substances. Even so fine a material as satin is embossed for this purpose. Embossed linen canvas made of a durable nature is coming much into use for decorative purposes. It is manufactured by passing the damped canvas over a metal roller, heated internally with steam, upon which the pattern is cut or engraved in *intaglio*. As the web passes over the roller, brushes or pads are applied to press the canvas into the indentations. By means of additional rollers, a backing of paper is pasted on, and when the whole is dry it is stiff and retains its shape. Japanese wall-papers, which are embossed in a somewhat similar manner to the linen canvas just described, but by the use of flat instead of cylindrical moulds, are now a good deal used in England. The patterns are often beautiful, the paper is strong, and the surface is made durable by coatings of oil and lacquer. Embossed canvas, paper, and leather for wall-decoration are commonly coloured and gilt.

Calicoes and other textiles are embossed by means of deeply engraved metal cylinders fitted into calender frames. The counter-roller is covered with felt, which yields sufficiently to allow the fabric to be pressed into the hollows of the die-cylinder. Sometimes the pattern is on two cylinders, being sunk on the one and raised on the other, after the plan of a die and its counterpart.

There is a method of embossing wood by saturating it with water, in which state a red-hot cast-iron mould is forcibly pressed upon it. Generally the wood is re-wetted, the mould re-heated, and the pressure applied several times before a complete impression of the mould is obtained. A curious mode of embossing wood was invented about 1830 by J. Straker. The design is drawn upon the surface to be thus decorated, and all the parts intended to be in relief are then carefully depressed by a blunt tool. The wood is next planed down to the level of the depressed portions. On being steeped in water, these will rise to their former level, forming an embossed pattern ready, when the wood is dry, to receive the finishing-touches of the carver. By a process invented in America, veneers of wood are embossed with metal dies. See DIE-SINKING.

The process of etching ornamental patterns with hydrofluoric acid on plate-glass, for the panels of lobby-doors, &c., is called 'embossing.'

Embossed, the heraldic term for anything bent like a bow—as, for example, the arm of a man.

Embracery, in the law of England, the offence of influencing jurors by corrupt means to deliver a partial verdict; the offence is punishable by fine and imprisonment.

Embrasures, in Fortification, are openings in the parapets, flanks of bastions, and other parts of the defence-works, through which cannon are pointed. See FORTIFICATION.

Embroidery (Fr. *broderie*) is the art of producing ornamental patterns by means of needle-work on textile fabrics, leather, and other materials which can be sewed over. The art is closely allied to tapestry-work, which is in fact intermediate between embroidery and weaving. The essential distinction is that, while embroidery is always worked upon an already woven texture, the basis of tapestry is a series of parallel strings or cords forming a kind of warp to which the various coloured yarns required for the pattern form the weft; and thus the cloth-making and the building-up of the pattern are one operation.

The art of embroidery, arising out of the universal craving for ornamentation, may be said

to be coeval and co-extensive with the use of clothing and furniture. It is practised with interesting and characteristic variations by the rudest tribes; and it is held in high esteem by the most gifted and highly cultured of nations. That it was early practised in oriental nations we have abundant evidence. It is most probable that the coat of many colours bestowed by Jacob on his favourite Joseph was a triumph of needlework, as looms at that period were capable of producing simple striped and checkered patterns only. Remains of Egyptian embroidery, as ancient as the days of Jacob, exist still; and of the art as practised by the early Egyptians Sir J. Gardner Wilkinson remarks, 'the many dresses painted on the monuments of the 18th dynasty show that the most varied patterns were used by the Egyptians more than 3000 years ago, as they were at a later period by the Babylonians, who became noted for their needlework.' The knowledge and skill acquired in Egypt by the Israelites enabled them to embroider the elaborate priestly robes and tabernacle furniture, 'the cherubim of cunning work,' 'the pomegranates of blue and of purple and of scarlet,' and the other needlework enumerated in the Book of Exodus. The 'goodly Babylonish garment' secreted by Achan at Jericho was probably an example of Babylonian skill in needlework; and indeed the frequency of allusion to embroidery in Scripture, as well as in the works of classical writers from Homer downward, testifies to the high appreciation and importance of the art in early times. Then, as in later ages, the triumphs of the art were reserved for priestly robes and for temple adornment.

The knowledge of artistic embroidery came to Europe from the nations of the East, where the art had its early home, and where it still is most largely appreciated and practised. To the Greeks and Romans it came from Phrygia, whence at Rome the embroiderer was known as *phrygio*, and gold embroidered work was called *aureo-phrygium*, from which we have the ecclesiastical English term *orphrey*. It was in mediæval times that the embroiderer's art attained its greatest perfection in Europe; and it is remarkable that the most highly appreciated examples of work were of English origin. The finest existing specimen of mediæval embroidery—the Syon Cope, now in South Kensington Museum—is English work of the 13th century. It is richly charged with scriptural subjects, and carries the armorial bearings of several of the most illustrious English families of the period. In historical interest, however, this cope falls far behind the Bayeux Tapestry (q.v.). Under the influence of the Oxford movement, and along with a revival in church architecture and glass-painting, has come a great revival of church embroidery as applied to altar-cloths, vestments, banners, &c.

Practically, embroidery is divided into two distinct classes of work: (1) that which embraces all kinds of artistic needlework done by the hand; and (2) the manufacturing industry which includes all embroidery done by machinery, and also such hand-needlework as is done on the large scale by following patterns mechanically impressed on the fabric to be ornamented.

In art embroidery the materials employed are fine coloured worsted yarns called crewels, tapestry wools, embroidery silks, gold and silver threads, spangles, and plates or discs of metal. There may also be used portions of feathers, the elytra of beetles, pearls, and precious stones; but these find their place principally in oriental embroideries. The textile basis may be any cloth, but the fabrics principally used are stout makes of linen, silks, satins, velvets, and flannels. Small work is done

without any special mounting, but for elaborate designs the fabric is fitted and tightly stretched on a frame. The variety of embroidery stitches is considerable, and must vary with the nature of the outline to be formed and the texture or subject to be imitated; and colours have, of course, to be carefully varied according to the necessities of the design when a coloured pattern is being worked. The principal stitches are the stem stitch, the satin stitch, the knotted stitch, the button-hole or blanket stitch, the chain or tambour stitch, the feather stitch, and the cushion or Berlin-work stitch, all of which may be best learned from practical manuals. In frame-work, 'couching' is largely employed, which consists in laying lengths of thread on the surface, and securing them by stitches through the cloth brought up at various points, variety of effect being obtained by the different disposition of these securing stitches. A distinct class of embroidery consists of appliqué or cut work, in which designs of different materials and colours are cut out and sewed down on the surface of the fabric to be ornamented. Inlaid appliqué consists of cutting precisely the same pattern out of two different fabrics, and inserting the one into the cut space in the other.

In its purely mechanical side, the embroidery trade embraces several distinct sections, of which may be enumerated (1) white embroidery, known also as Swiss or Scotch sewed work, for which work the muslin or other fabric is printed with a pattern made up of holes of different dimensions, which are either cut or punched out, and their edges sewn over with a button-hole stitch; (2) embroidery in gold, silver, and coloured silks, for official costumes, civil and military, badges, &c.; (3) embroidery in crewels, or other coloured wools, coloured silks, &c., mostly done for furniture decoration, such as borders of tablecovers, &c.; and (4) there may be included ornamental braiding with braids of various colours, principally for ladies' costumes. To a great extent these various kinds of embroidery can be worked by one or other of the machines which have been devised for embroidering. The first successful embroidery machine was that invented by M. Josué Heilmann, of Mulhausen, patented in England in 1829. With Heilmann's machine, or the modifications of it which have since been introduced, one person can guide from 80 to 140 needles working simultaneously, and producing so many repeats of the same design. The details of the construction of the machine are complex, but the principle of its action may be easily understood. The needles, with their eyes in the middle, are pointed at each end, so that they may pass from both sides of the work without being turned. Each needle is worked by two pairs of artificial fingers or pincers, a pair on each side of the work, and these grasp and push the needle through from one side of the work to the other. A carriage or frame connected with each series of fingers does the work of the human arm, by carrying the fingers to a distance corresponding to the whole length of the thread. The frame then returns to exactly its original place, and the needles are again passed through to the opposite set of fingers, which act in like manner. Were the work which is mounted in a frame to remain stationary, the needles would thus pass merely backwards and forwards through the same hole. But the frame is mounted to move in every direction, and according to its motion stitches varying in length and in direction are made corresponding to the lines of the design. The motion of the frame is governed by a pantograph machine (see PANTAGRAPH), the free end of which, moving over an enlarged copy of the design, moves the frame at each successive stitch into the position required for the production of

the various repeats of the pattern. Embroidery patterns, in a variety of knotted, tambour, and other stitches, and ornamental braiding, are now very largely done by means of the Bonnaz machine, the invention of M. Antoine Bonnaz, first patented in Britain in 1868. This apparatus is in appearance and construction like the ordinary sewing-machine, but in place of a needle it has a hooked looper which passes down through the work and brings the thread up from below, looped around it to make a knotted stitch on plain for the ordinary tambour stitch. It is further provided with a universal feed-motion, so that the work can be guided to follow the most intricate and sharp-turning pattern. A modification, invented by M. E. Cornely, is in extensive use for ornamental braiding.

Higgin, *Handbook of Embroidery*, ed. Lady Marian Alford (1879); Mrs. Mary Barber, *Drawings of Ancient Embroidery* (1881); Lefebure, *Embroidery and Lace* (Eng. trans. 1888); Mrs. Christie, *Embroidery and Tapestry Weaving* (1920), and *Samplers and Stitches* (1921); Kendrick, *Book of Embroidery* (1921).

Embrun, a fortified town in the French department of Hautes Alpes, crowns a rock-platform on the right bank of the Durance, and at the base of Mont St Guillaume (8344 feet), 23 miles E. of Gap by rail. It looks better from without than within; but its cathedral has a lofty Romanesque tower. Pop. 2400. Embrun occupies the site of *Eboracum*, capital of the Caturiges, and an important Roman station. It was the seat of a bishopric from 374 to 1802.

Embryo (Gr.), a term usually restricted (*a*) to the unborn young animal, or (*b*) to the rudimentary young plant, especially when within the seed. The term *fœtus* is equivalent to embryo, but is restricted to mammalian development. The term *larva* is also applied to a young animal which is more or less markedly different from the adult form. See EMBRYOLOGY, REPRODUCTION, SEED.

Embryology is that department of biology which reads the development of the individual organism. It is a succession of studies in anatomy and physiology which, when read into unity, give the history of the organism from its earliest individual appearance on to that vague point when it may be said to exhibit all the main features of adult life. The investigation necessarily takes two forms: a description of the structure of successive stages (*morphological*), and an analysis of the vital processes associated with each step (*physiological*). Nor is any embryological investigation complete which does not link the everyday development of individuals with the historical evolution of the race.

History.—Although the development of the chick, so much studied in embryological laboratories today, was watched 2000 years ago in Greece, it was only in the scientific renaissance of the 17th century that observation began to grow strong enough to wrestle with conjecture. Harvey, who towered as a strong genius above his contemporaries, and saw much farther, sought in 1651 to establish two main propositions: (1) that every animal was produced from an ovum—*ovum esse primordium commune omnibus animalibus*; and (2) that the organs arose by new formation (*epigenesis*), not from the mere expansion of some invisible preformation. These valuable generalisations were not, however, accepted, and even observations like those of Malpighi seemed for the time to tell against Harvey's prevision. The time was past for absolutely fanciful theories, and yet the domi-

nant doctrine which persisted even into the 19th century was mystical enough. The germ, whether egg or seed, was believed to be a miniature model of the adult. 'Preformed' in all transparency, the organism lay *in nuce* in the germ, only requiring to be 'unfolded.' Just like a bud which hides within its hull the floral organs of the future, so was every germ. 'There is no becoming,' Haller said; 'no part of the body is made from another; all are created at once.' But the germ was more than a marvellous bud-like miniature of the adult; it included all future generations. That germ lay within germ, in ever smaller miniature, after the fashion of an infinite juggler's box, was the logical corollary of the theory of preformation and unfolding. One of the controversies of the time was whether ovum or sperm was the more important. The ovists asserted the claims of the ovum, which only required to be awakened by the spermatozoon to begin its unfolding. The animalculists, on the other hand, maintained that the male element contained the preformed germ, and that the ovum was merely for its preliminary nutriment.

All this was virtually shattered by Wolff (1759), who reasserted Harvey's epigenesis, and showed that the germ consisted of almost structureless material, and that the process of development was a gradual organisation. Yet Wolff's work had not the effect of entirely demolishing preformationist conceptions. They lingered on, and had this much truth in them that the germs are indeed potential, though not miniature, organisms. To some extent Wolff reacted too far against the mystics in his emphasis on the simplicity of the germ, so that a correction was necessary when the cellular character of the reproductive elements was realised about a hundred years later. The observation of structural progress was slow in gaining self-confidence, for it was not till 1817 that Pander took up Wolff's work virtually where he left it. He was immediately reinforced and soon left behind by Von Baer, whose results laid a firm foundation for modern embryology. Since the establishment of the Cell-theory (see CELL) in 1838-39, and the associated researches which showed that the organism starts from a fusion of two sex-cells, and that development consists in the division of the fertilised ovum and differentiation of the results, progress has been both sure and rapid. The more modern demonstration of the fact of evolution has afforded a fresh impulse by its interpretation of the present as the literal child of the past.

The *egg-cell* or *ovum* is in all organisms the starting-point of the embryo, but development can rarely begin till this female element is supplemented by the male cell or spermatozoon. These sex-cells are liberated units of the parent-organism, but in most cases they stand in marked contrast to the great congeries of cells which form the 'body.' All the component units of the organism are indeed lineal descendants of a fertilised ovum, but the 'body'-cells become greatly changed into muscle, nerve, skeleton, and the like, while the reproductive cells retain with more or less intactness the characters of the original parent germ. It is this fact which makes the reproduction of like by like possible.

The unicellular animals or Protozoa, having obviously no 'body,' are directly comparable to the sex-cells of higher animals. The 'body' is the addition which makes the difference. In a few Protozoa, however, the results of the division of a unit remain associated together, and a loose colony of cells arises. Such a Protozoon behaves like an ovum or like a primitive male-cell in any of the higher animals. The loose colony may be very unstable, and may soon resolve itself into its

component units, exactly as the primitive male-cell, which has divided into a clump of spermatozoa, breaks up and sets these active units free. But the colony may be more stable and retain its continuity (like a segmented ovum), thus bridging the gulf between unicellular and multicellular organisms. In such cases certain cells are set apart as reproductive, and eventually set adrift to start a fresh colony. This is the beginning of the differentiation of special reproductive cells. At first these were probably all alike and able to develop of themselves, but in a manner which does not concern us here (see SEX) they became differentiated as male and female elements, mutually dependent and complementary.

The ovum has all the essential characters of an ordinary animal cell. The cell-substance consists of Protoplasm (q.v.) and of material ascending to or descending from that climax. As in other cases, the cell-substance may be traversed by a network, —one of the intricacies which modern microscopic technique has revealed. Like other cells, the ovum includes a central differentiation or nucleus, technically called the germinal vesicle. This exhibits the essential nuclear elements in the form of rods, bands, or network, and other minute features described in the article CELL. The nucleus plays a most important part in the history of the ovum, and is believed to be the bearer of the hereditary characteristics.

As to the precise origin of the ova, it is enough here to state that in sponges they are simply well-fed cells in the general substance (middle stratum) of the sponge; that in Cœlenterates they may originate from outer or from inner layer; while in other animals they are almost always associated with the middle layer of the body, and as we ascend are more and more restricted to a distinct region or to a definite organ—the ovary.

The very young ovum is often at least like an Amœba (q.v.), and in Hydra (q.v.) this character persists. The first chapter in its history is one of nutrition and growth. This often occurs at the expense of neighbour cells, and the ovum may be the successful survivor of a clump. In other cases the nutriment, for immediate or future use, may be derived from the vascular fluid of the animal, or from special glands, which are sometimes simply degenerate portions of an originally larger ovary. The capital of nutriment thus derived is distinguished as the yolk. It varies greatly in quantity and disposition, and has great influence in determining the precise form which the future division of the ovum will take. It may be small in quantity and uniformly diffused through the cell, as in mammalian ova; there may be a larger quantity, which sinks to the lower part, as in frog spawn; there may be a very large amount, which quite dwarfs the genuine living matter, as in birds' eggs; or there may be a central accumulation, as in crustaceans and insects. The egg is very generally surrounded with some membrane, sheath, or shell, made by itself, or contributed by surrounding cells, or the product of special glands. In such envelopes there is often a special aperture (micropyle) through which alone the spermatozoon can enter. Hard shells like those of birds' eggs must obviously be formed after fertilisation has taken place.

The Male-cell or Spermatozoon.—In the unicellular organisms, among which we find the key to all beginnings, two cells, unable apparently to live independently, unite, and thus make a fresh start. In such cases the two units are usually similar in appearance, though doubtless different in chemical state. Sometimes, however, a small active cell unites with a larger and more passive

neighbour, and here we find the first hint of the profound difference between the sexes—a difference of which the contrast between spermatozoon and ovum is literally a concentrated expression.

The spermatozoon is a true cell, though the nuclear portion often predominates over the cell-substance. It is one of the smallest animal cells,

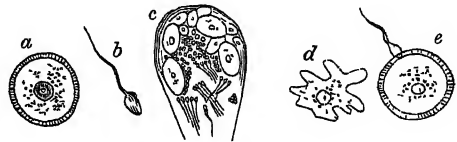

Fig. 1.—Germ-cells:

a, ovum showing egg membrane, granules, and germinal vesicle; b, spermatozoon; c, hermaphrodite gland of snail, with ova and sperms; d, amoeboid ovum; e, coalescence of sperm-cell and egg-cell.

as the ovum is one of the largest; it is highly active, while the ovum is peculiarly passive; it rarely bears any nutritive material, while the ovum is very generally weighted with yolk. In its minute size, active locomotor energy, and persistent vitality, the sperm-cell resembles a flagellate Monad among Protozoa, while the ovum is strictly comparable to an Amœba or to one of the yet more passive or encysted forms. In most animals the spermatozoon exhibits three distinct parts: (a) the 'head,' or essential portion, consisting almost wholly of nucleus; (b) the mobile 'tail,' of contractile protoplasm which drives the 'head' along; and (c) a small middle portion connecting the head and tail.

In its origin the male-cell resembles the ovum, and the two cells are of course the physiological complements of one another. In history, however, the ovum is strictly comparable not to the sperm, but to the cell which divided to give rise to the sperms. The primitive male-cell, or mother-sperm-cell, is the homologue of the ovum. Just as the latter divides in segmentation, so the mother-sperm-cell divides, and the divisions exhibited in what is technically called spermatogenesis are closely parallel to the various modes of segmentation exhibited by ova. The mother-sperm-cell segments, but the results have no coherence; they go asunder as spermatozoa. Thus, though all cells may be said to rank as equals, the sperm-cell has a longer history behind it than the ovum. The differences both in form and history express the great differences in chemical constitution which are summed up in the words male and female.

Maturation of the Ovum.—The egg-cell having attained its definite size or limit of growth, usually exhibits a somewhat enigmatical phenomenon known as the extrusion of polar globules. In the great majority of cases it buds off two tiny cells, by a process of cell-division, in which the nucleus plays its part. In the course of maturation, usually in the formation of the first polar body, a meiotic or reducing division takes place, the number of nuclear elements or chromosomes being reduced to half the normal number—in preparation for the entrance of the spermatozoon, which undergoes a similar reduction in the course of spermatogenesis. If there were not this reduction the number of chromosomes would be doubled in fertilisation. The polar cells come to nothing, though they may linger for a while in the precincts of the ovum. Their expulsion usually takes place before fertilisation has even begun, but sometimes is subsequent to the entrance of the spermatozoon into the ovum. In some parthenogenetic ova, which develop without fertilisation, only one polar globule is formed.

Fertilisation.—The 'ovists' thought that the

ovum was all-important, and only required the sperm's wakening touch to unfold its preformed model. The 'animalculists' were equally certain that the spermatozoon was all-important, and only required to be fed by the ovum. Even after the mutual dependence of the sex-elements had been recognised, the opinion prevailed that contact of the two was unessential, and that by an *aura seminalis* fertilisation was possible. In 1677 Hamun and Leeuwenhoek first distinctly saw spermatozoa; in 1780 Spallanzani showed by artificial fertilisation that the eggs must come into contact with the seminal fluid; in 1843 Martin Bary observed the spermatozoon in union with the ovum of the rabbit; in 1846 Kölliker proved the cellular origin and nucleated character of the male elements; and in 1872-75 Bütschli and Auerbach observed two nuclei in fertilised eggs. The dates of these representative discoveries show how gradually the result has been reached that the essence of fertilisation is the intimate union of a male and a female cell.

It is needless to cite the numerous investigators who have made the following statements possible:

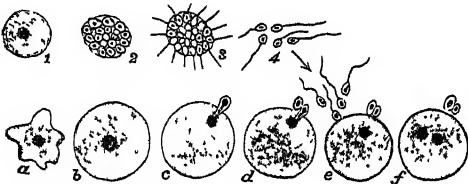

Fig. 2.—Development of Sperms; maturation and fertilisation of Ova (diagrammatic):

1-4, Division of a mother-sperm-cell or primitive-male-cell into a ball of spermatozoa which breaks up; 5-7, maturation and fertilisation of ovum; 8, anucleoid young ovum; 9, later stage; 10, budding off of a first polar cell; 11, budding off of a second; 12, spermatozoa round ovum, one entering; 13, male and female nuclei about to fuse on completion of fertilisation.

(1) Only one male element really unites with the egg-cell. By a sudden change after the entrance of one sperm the ovum usually ceases to be receptive. The entrance of more than one occasionally occurs, but the result is pathological. (2) The union is very intimate; the nuclei are at least as important as the protoplasm, and according to most authorities much more so. (3) The two nuclei are attracted or drawn to one another, and fuse intimately to form a single nucleus of double origin. (4) Intimate as the union is, its orderliness is not less conspicuous; half of the result is still traceable to the male and half to the female.

It may be said that fertilisation implies three or four distinct things. It implies a mingling or combination (amphimixis) of the paternal and maternal hereditary qualities, which are in great part at least bound up with the nuclear bodies or chromosomes. In the process of maturation, both of ova and spermatozoa, the number of chromosomes (which is definite for each species) is reduced to one-half; in fertilisation the number is obviously restored to the normal. It seems also certain that the spermatozoon supplies to the ovum some stimulus which sets the process of cleavage or segmentation agoing, or removes some inhibition which hindered this. Lastly, it is known that the spermatozoon introduces (in its middle piece) a minute body known as the centrosome (see CELL), which plays a very important part in the subsequent division.

In connection with the import of fertilisation it is interesting to notice (1) that a non-nucleated fragment of ovum may be successfully fertilised by a spermatozoon, and may develop into a normal embryo (merogony); and (2) that in several cases

(sea-urchin, starfish, worm, mollusc) an ovum may be induced to develop in the absence of a spermatozoon, the normal liberating stimulus being replaced by a variety of artificial stimuli, such as temporary immersion in sea-water, in which the ordinary proportions of the salts have been slightly altered. Such experiments clearly indicate that each of the germ-cells, whether ovum or spermatozoon, has in it a complete equipment of hereditary qualities.

Thus artificial parthenogenesis, as it is called, occurs as high in the scale as Amphibia. If frog's eggs are pricked with a fine needle, and washed in blood, which need not be frog's blood, and then restored to their normal medium of pond-water, they develop readily and normally. The embryos have been reared to the stage of small frogs, and may be either males or females. In ordinary cases of artificial parthenogenesis there seem to be always two processes: (a) an exciting process, which induces a segmentation of the egg; and (b) a counteractive process, such as restoration to the natural medium. Unless the counteractive process occurs the segmentation of the egg ends fatally.

Segmentation.—Soon after the essential act of fertilisation has been accomplished in the intimate union of the nuclei, the egg begins to divide. What physical and chemical attractions and repulsions operate in this process we do not know. It is certain that the nuclear elements, which play a very important part throughout, have what we cannot but call a strong individuality of behaviour. It has been established that the double nucleus of the fertilised ovum is accurately composed half of female and half of male elements. When the egg divides into two, the nucleus of each daughter-cell is again half male and half female, and it is probable that this exact dualism persists yet further.

The different ways in which ova divide depend mainly upon the quantity and disposition of the passive yolk-material. (1) When there is very little nutritive capital, and that uniformly diffused, the whole ovum divides, vertically and horizontally, till a sphere of approximately equal cells is formed. This total segmentation occurs, for instance, in the ova of sponge, starfish, lancelet, and mammal. (2) In the ova of the frog, where the actual process of division may be most conveniently watched, there is more yolk, which has chiefly sunk to the lower hemisphere of the egg. Division is still total, but after a few segmentations it will be seen that the upper hemisphere cells are dividing more rapidly and are becoming markedly smaller than those in the lower part. The segmentation is total but unequal. (3) In the ova of birds and reptiles

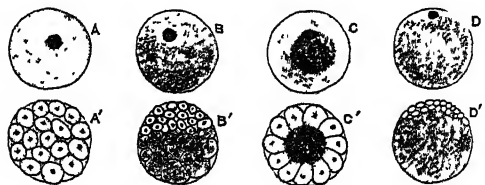

Fig. 3.
Relation of Yolk to division of Ovum (diagrammatic):

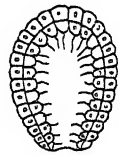

A, little and diffuse yolk. A', total equal division.
B, more yolk at lower pole. B', total unequal division.
C, central yolk. C', peripheral division.
D, much yolk. D', partial division.

and many fishes there is a large quantity of yolk, and the formative substance lies like a drop on the upper surface of the nutrient mass. Division is restricted to the formative protoplasm, and thus the segmentation is conspicuously partial. (4) In the

ova of crustaceans, insects, and their allies, the yolk usually accumulates in the centre of the ovum as a more passive, nutritive core, surrounded by the active, formative protoplasm. The latter divides, and forms a sphere or ellipsoid of cells around the less markedly divided yolk. In *Peripatus*—the survivor of ancestral insects—the whole ovum segments, but the cells are not for a while defined off from one another, so that the result looks like a giant Protozoon with numerous nuclei. Hints of this are seen in other cases.

Morula and Gastrula.—The result of segmentation is a ball of cells, differing according to the above described modes of division. When a wide cavity has been left, between the cells as they multiplied, a hollow sphere is formed, technically called a *blastosphere*; if no such conspicuous 'segmentation cavity' has been left the result is an almost solid mulberry-like ball of cells—a *morula*. When the division is partial, mainly confined to an area of formative protoplasm lying upon a nutritive mass, the result is a disc of cells which by-and-by spreads round the yolk. Such a segmented area is generally known as the *blastoderm*. (See D', fig. 3.)

The next decisive chapter is one of infolding, or the formation of a *gastrula*. In the simplest cases one hemisphere of a hollow ball of cells is dimpled or invaginated into the other. More accurately, the one hemisphere sinks into and becomes surrounded by the other. The sphere becomes a two-layered sack or *gastrula*, with an opening technically called the *blastopore*. In many other cases—e.g. fishes, reptiles, and birds—owing to the yolk, complete invagination is not possible. An infolding still occurs, but it is no longer conspicuous, and the *gastrula*-stage is thus disguised. It must also be noted that the two-layered condition may arise by *arrangement* of the cells, without there being any process that can be called invagination. Thus, in

the oval ciliated embryo or *planula* of most Hydrozoa, the two layers have been frequently observed to arise by a process of internal differentiation, known as *delamination*.

The Germinal Layers.—Even in a simple colony of cells like a *Volvox* all the units do not remain alike. Inside cells are in different conditions from outside cells, and division of labour with consequent difference of structure is bound to occur. So again, in the ball of cells into which the ovum divides, the one hemisphere with heavier material is usually different from the upper hemisphere, which is specifically lighter and less encumbered with reserve material. Even in the *morula* or *blastosphere* differentiation has begun.

But we have just seen that by the folding of one hemisphere into the other, or in other ways, a *gastrula* often more or less modified arises. The embryo thereby attains definitely differentiated layers—outer and inner. The preformationists spoke of development as an unfolding; we now insist on an infolding. The layered character of the embryo was early recognised by Wolff, and yet more clearly by Pander and Von Baer, but its fundamental import can hardly be said to have been realised till Huxley in 1849 compared the outer and inner cell-layers of Coelenterates to the outer and

inner layers which embryologists had begun to demonstrate in development. Soon afterwards Allman gave to the outer and inner layers of Coelenterates the names *ectoderm* and *endoderm*, which are now universally used for the outer and inner layers of every embryo. The results reached by Huxley and Haeckel, Kovalevsky and Ray Lankester, and many others, have made it certain that the formation of these two germinal layers is constant in animals, that they are exactly comparable throughout the series, and that with few exceptions they give rise to precisely the same adult structures.

In sponges and Coelenterates only two genuine layers of cells are developed. A middle stratum, seen in faint suggestion in the common *Hydra*, may indeed appear, and may be of the greatest importance in the structure of the animal, but embryologists are not inclined to allow this—the so-called *mesoglaea*—to rank as a distinct layer.

In higher animals, however, there is a definite middle layer or *mesoderm* between the other two. Its history involves much greater difficulty than that of the ectoderm and endoderm; it seems as if it might arise in some half-dozen different ways. One common mode of origin has been emphasised by the brothers Hertwig in what they call the 'Coelome-theory.' The inner layer arises by an infolding of the outer, and a primitive gut-cavity (*archenteron*) thus results. Now begins an outfolding. From the gut-cavity two sacks (*coelome-pockets*) grow out, one on either side, insinuating themselves between the first two layers. The cavities of the sacks form the future body-cavity of the animal; the outer and inner walls form the corresponding two divisions of the mesoderm. However this middle layer arises, it finally exhibits an inner and an outer division, so that the Hertwigs speak of *four* germinal layers. The outer (parietal or somatic) portion of the mesoderm clings to the external body-wall, forming muscles and the like; the inner (visceral or splanchnic) portion cleaves to the internal organs.

Origin of Organs.—With few exceptions, the same organs and structures arise from the same layers—e.g. the nervous system from the ectoderm, the lining of the mid-gut from the endoderm. (a) The *ectoderm* or *epiblast* gives origin to outer skin or epidermis, external skeleton, superficial glands, sense-organs, nervous system, the infoldings at both ends of the gut, and probably to the primitive excretory (segmental) duct. (b) The *endoderm* or *hypoblast* forms the lining of the mid-gut, and necessarily, too, of outgrowths from it, such as the lungs and various glands. In vertebrates it also gives rise to that important skeletal axis—the notochord—which always precedes the 'backbone.' (c) The *mesoderm* or *mesoblast* gives rise to all the rest. That is to say, the under-skin, the muscles, the connective tissue, the internal skeleton, the lining of the body-cavity, the heart and the blood, and the like are all mesodermic. The reproductive organs, though to some extent structures by themselves, also arise, in the great majority of cases, in connection with the mesoderm. It must be noted, further, that while the main part of a structure is referable to one of the three layers, the entire structure is very often composite. Thus the eye of vertebrates mainly arises as an outgrowth from the brain, but some of the less essential parts are furnished by the mesoderm. The outgrowths from the mid-gut are in origin endodermic, but they too are always aided by the middle layer.

Physiological Embryology.—The immense progress of embryology within recent years has been almost wholly morphological. Of the physiological conditions of development we know relatively little. The later stages of embryonic life in higher animals have been studied by Preyer and others with much success, but this is but the threshold of investiga-

tion. A few luminous results as to the architectural conditions are due to the courage of His and Rauber, who have followed the earlier suggestions of Pander and Lotze. The task, which is involved in stupendous difficulties, has been continued in the experimental investigations of O. Heitwig, Fol, Pfleger, Born, Roux, Schultze, Geilach, and others.

The deep questions of embryology, which were in Aristotle's mind when he wrote his *De Generatione*, are with us still. How are the heritable characters summed up potentially in the germ-cells? How do these characters gradually find expression or realisation in the individual becoming, so that what we call differentiation and integration result? What is the nature of that compelling necessity which mints and coins the chick out of that minute drop of living matter lying like an inverted watch-glass on the top of the yolk? What is the regulative principle of the ordered progress which, by intricate and often strangely circuitous paths, leads from apparent simplicity to obvious complexity—to the fully formed organism? And how is it that the germ-plasm, without encumbrance or embarrassment, has been continuously able to enregister within itself the gains of racial evolution so that these are entailed on the individual?

These questions do not at present admit of answer, and there are many expert embryologists, like Driesch, who are convinced that they are unanswerable in lower terms—that is to say, in terms of chemical and physical formulae. Be this as it may, the history of biological science shows the value of pushing analysis as far as it can be applied. Thus, while the deeper questions remain unanswered, embryologists press on with their inquiry into the external factors of development—such as light, temperature, oxygen, osmotic pressure, and the chemical composition of the medium; and with their inquiry into the processes that actually go on in the developing embryo—the fermentations and other chemical changes, the phenomena of surface-tension and capillarity, the protoplasmic movements, the cell-divisions, the influence of part on part. It goes without saying that there is nothing known in regard to development which is at variance with the established results of chemistry and physics, but it is likewise certain that in the present state of science we cannot give a physico-chemical interpretation of even the simplest data of embryology.

Generalisations.—(1) *The Ovum-theory.*—In all cases of ordinary sexual reproduction among plants or animals the offspring develops from a fertilised egg-cell. This is the ovum-theory prophesied by Harvey in 1651, again almost realised by Wolff in 1759, but only demonstrated about a hundred years later when the organism was at length analysed into its component cells (see CELL). The fact that every plant or animal begins at the beginning again, at the level of the Protozoa or single-celled organisms, Agassiz does not hesitate to call one of the greatest discoveries in the natural sciences in modern times.

(2) *The Gastræa-theory.*—The simplest animals are single cells; these occasionally form loose colonies or balls of cells; next come sack-like two-layered organisms, such as the simplest sponges. These are the first three grades among living animals, but they also correspond to the first three chapters in the life-history of each organism. The single cell (the ovum), the ball of cells (the morula or blastosphere), the sack of cells in two layers (the gastrula), we have seen to be the first three stages in development. As this gastrula-stage always occurs, though sometimes disguised by the yolk, in the life-history of animals, Haeckel justly emphasised it as the individual's recapitulation of an ancestral state. The simplest, stable, many-celled animal he believed to be like a gastrula (see fig. 5),

and he called this hypothetical ancestor of all higher animals a gastræa. A few living animals are still almost at this level; all animals pass through it in

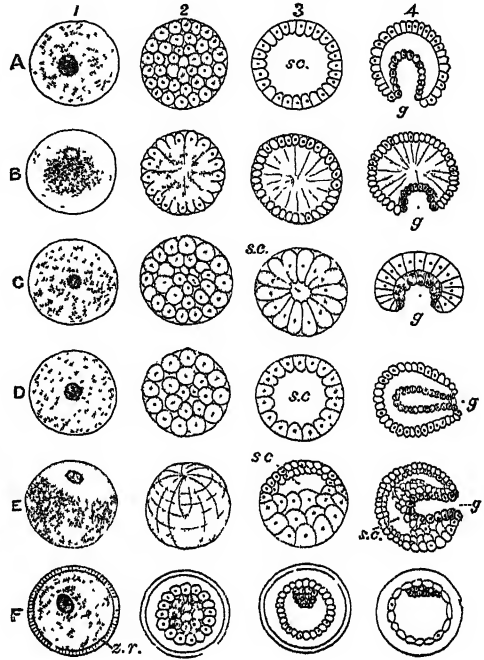

fig. 6.

The First Stages in Development (not drawn to scale):

1, fertilised ovum; 2, ball of cells; 3, the same still more divided, or in section; 4, the gastrula (except in F). A, sponge, coral, earthworm, or starfish; B, crayfish, or other arthropod; C, river snail, or other mollusc; D, lancelet, tunicate, &c.; E, frog, or other amphibian; F, rabbit, or other mammal; s.c., segmentation cavity; g, gastrula invagination; z.r., zona radiata, or porous envelope. Darkly shaded cells are endoderm, lighter are ectoderm, dots are yolk granules.

their gastrula-stage. The gastrula is a recapitulation of the ancestral gastræa. Rival conceptions of what the first stable, many-celled animal was like have been since proposed, but the gastræa-theory still holds the field.

(3) *The Fact of Recapitulation.*—The gastræa-theory is only a special case of a more general proposition—that the individual recapitulates the history of its kind. That the past lives in the present, or that we individually retrace, for instance in our intellectual development, the paths made by our ancestors, is a familiar idea which it is one of the charms of embryology to realise in the life-history of each organism. At an early date Von Baer expressed this in his law, that structural progress or differentiation in development was from a general to a special type. 'In its earliest stage,' he said, 'every organism has the greatest number of characters in common with all other organisms in their earliest stages; at each successive stage the class of embryos which it resembles is narrowed.' In the life-history of a mammal it is possible to trace how the germ at first lingers as it were among the Protozoa; how it divides and passes quickly through the transitional 'ball of cells' stage; how the embryo undergoes its first great differentiation, like all other multicellular animals, in becoming a two-layered gastrula, taking its place beside the ancestral Metazoa; how it by-and-by acquires some of the characters of a young worm, and then of a very simple backboned animal, like a primitive

fish; how with increasing complexity it ranks with reptilian embryos; and lastly, how the fœtus acquires mammalian features, vague and general at the outset, but gradually becoming like those of nearly related forms. Von Baer himself confessed, as every embryologist would do, that with three embryos of higher Vertebrates at the same stage before him, he could not, without close examination, tell one from the other. The accompanying

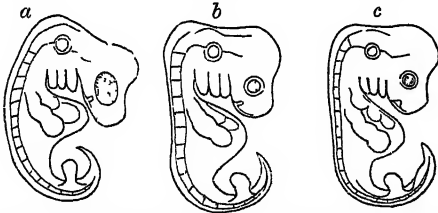

Fig. 7.—Embryos of fowl (a), dog (b), and man (c).
(After Haeckel.)

figure of the embryos of a bird, a mammal, and the human species clearly illustrates this close resemblance in early life.

Spencer expressed the progress from simple to complex, from general to special, as a differentiation from homogeneous to heterogeneous, in which the individual history runs parallel to that of the race. The most luminous reading of the fundamental fact is that of Haeckel. The individual development is a recapitulation of the historic evolution of the race. A curve symbolising the turns and twists in the life-history of one of the higher Vertebrates, for instance, is seen to be a reflection of the great bends and branches of the genealogical tree which expresses the historic lineage. The development of the individual microcosm is a summary—often a shorthand summary—of the evolution of the macrocosm of the race. Most pithily, though most technically, he sums up his ‘fundamental biogenetic law’ in the words ‘Ontogeny recapitulates phylogeny.’ The fact is very vividly illustrated in many of the more patent life-histories, such as those of crustaceans, insects, and amphibians, where the hatched young follow the rails laid down by their respective ancestors (see AMPHIBIA, CATERPILLAR, CRUSTACEA). Parker happily compares watching development—in which he is one of the modern masters—to reading a palimpsest; below the superficial script there are older and ruder characters, and below these more primitive still. Two cautions must be emphasised. The development is often shortened in its path; circuitous twists, in what we believe to have been the historic course, are skipped by the individual; the momentous steps, however, are always paralleled in the two histories. The individual development may be said to follow the main line of progress, but does not go off into side-lines. Thus the resemblance is between embryos. The embryo bird is hardly like a reptile, but it is always in its development like an embryo reptile. Nor must it be imagined that this fact of recapitulation exactly explains itself. That the present is child of the past does indeed shed great light on the individual’s recapitulation of ancestral stages, but the metaphors are apt to suggest that the developing organism has somehow a feeling for history, or that the hand of the past is literally upon it as it grows. It is necessary to get beyond mere metaphors of unconscious memory and the like, and to realise that the same internal conditions which in the long past led to certain momentous changes are still really present doing the same for the individual. The fundamental problem is to elucidate the chemical

and physical conditions which represent the living hand of the past upon the development of the present, or to understand how the living matter of the embryo is at each stage both the material and the architect of its upbuilding.

(4) *Continuity of Germinal Protoplasm.*—In flowering plants there is a conspicuous contrast between the reproductive system and the general ‘body.’ In all organisms this antithesis is fundamental, and the recognition of the fact has shed much light upon the problems of development and heredity. In the simplest animals a portion of the cell is separated off to start a new individual; and as this is virtually continuous with the parent the reproduction of like by like is natural and necessary. In a few animals (some worm-types, crustaceans, insects, &c.), when the ovum has multiplied to a limited extent, by the usual process of division, certain of its descendants, as yet very like the original ovum, are set apart to form the reproductive cells of the offspring, and take no share in building up the ‘body.’ The germ-cells of the offspring, thus early insulated, are in a real sense continuous with the parental ovum; they retain some of the living capital intact, continue the protoplasmic tradition unaltered, and when themselves liberated will naturally do what the original germ-cells did. Thus the reproduction of like by like becomes more intelligible, and we reach the conception of a continuous necklace-like chain of immortal germ-cells from which the mortal bodies of successive generations are budded off. This conception has been more or less clearly suggested by numerous naturalists—Owen, Haeckel, Jäger, Brooks, Galton, Nussbaum, and others, but has been elaborated by Weismann in his theory of the continuity of the ‘germ-plasma.’ A continuous chain of germ-cells is only demonstrable in a few cases; often they become distinct only at a relatively late stage in the development of the offspring. Therefore Weismann insists not on a continuity of germ-cells from those of the parent to those of the offspring, but only on a continuity of ‘germ-plasma.’ ‘In each development a portion of the specific “germ-plasma” which the parental ovum contains is not used up in the formation of the offspring, but is reserved unchanged for the formation of the germ-cells of the following generation.’ The germ-plasma which keeps up the continuity has its seat in the nucleus, is a substance of definite chemical and special molecular constitution, has an extreme power of persistence and enormous powers of growth. The general idea is simple enough—an offspring starts with a capital of living matter which is virtually the same as that from which its parents started. Therefore the results are in a general way the same, and the constancy of the species is sustained. How this is modified by variations is not here relevant.

Embryo-sac. See OVULE, SEED.

Emden, a port in the Prussian province of Hanover, situated a little below the embouchure of the

Ems into Dollait Bay, 77 miles WNW of Bremen. It has retained not a few antique houses in the Dutch style, and is intersected by numerous canals, which are crossed by about thirty bridges. The harbour accommodation has been improved in connection with the making of the canal from the Ems (q.v.) to the Jade, and now comprises an inner and an outer harbour—the latter allowing large sea-going vessels to come to the quays from Dollait Bay (2 miles S.). The finest building is the town-hall (built in 1574–76), containing a library and a curious collection of ancient arms and armour. Emden has a large trade in corn, cattle, butter, cheese, coal, timber, wine, and tea, and manufactures machinery, cables, cement, leather, and tobacco, but its principal industry is deep-sea fishery and allied occupations. Pop. 27,000. Emden belonged originally to East Friesland, and after various vicissitudes was created a free imperial town under the protection of Holland in 1595, and remained so until 1744, when it passed to Prussia. After belonging successively to Holland, France, and Hanover, it again became Prussian in 1866.

Emerald (Span. *esmeralda*, Fr. *émeraude*, Ger. *smaragd*, Gr. *smaragdos*), a mineral generally regarded by mineralogists as merely another variety of the same species with the Beryl (q.v.), with which it essentially agrees in composition, crystallisation, &c., differing in scarcely anything but colour. The emerald, which, as a gem, is very highly esteemed, owes its value chiefly to its extremely beautiful velvety green colour. It is composed of about 67–68 per cent. of silica, 15–18 of alumina, 12–14 of glucina, and minute proportions of sesquioxide of chromium, magnesia, and carbonate of lime. Its colour is ascribed chiefly to the oxide of chromium which it contains. Its specific gravity is 2.70–2.76. In hardness it is rather inferior to topaz. The localities in which the emerald is found are very few. The finest have long been brought from Colombia (q.v.), where they are obtained from veins traversing clay-slate, hornblende slate, and granite; and valuable stones also come from the Upper Orinoco, in Venezuela. Stones of inferior quality are found in Europe, imbedded in mica-schist, in the Henbach Valley, in Salzburg. They also occur in the Urals; and some old mines in Upper Egypt have been found to yield them. This gem, known from very early times, was highly prized by the ancients. Pliny states that when Lucullus landed at Alexandria, Ptolemy offered him an emerald set in gold, with his portrait engraven on it. Many wrought emeralds have been found in the ruins of Thebes. Nero, who was near-sighted, looked at the combats of gladiators through an eye-glass of emerald, and concave eye-glasses of emerald seem to have been particularly esteemed among the ancients. As a precious stone, the emerald is rarely without flaw. Its value also depends much on its colour. A very perfect emerald of six carats has been sold for £1000. It appears not improbable that emeralds have been found in the East, in localities not at present known, but the name Emerald or Oriental Emerald is often given to a very rare, beautiful, and precious green variety of Sapphire (q.v.).

EMERALD COPPER is a beautiful and very rare emerald-green crystallised mineral, also called Diopside, found first and chiefly in limestone in the hill of Altyn-Tube (Altai Mountains), and also obtained in the Urals and the South American Cordilleras. It is composed of about 39 parts silica, 50 protoxide of copper, and 11 water.

Emeritus (Lat.), a term applied originally to a Roman soldier who had served out his time, and been discharged on something equivalent to our half-pay. It is now commonly employed to design-

nate certain functionaries, such as professors, who have been honourably relieved from the duties of their office, on account of infirmity or long service, and who are usually granted a retiring allowance.

Emerson, RALPH WALDO, one of the most original thinkers of his time, essayist, and poet, was born in Boston, Massachusetts, on the 25th May 1803, and died in Concord, Massachusetts, on the 27th April 1882. He came of what his own people would call the best New England stock, namely, from a long line of educated and respected ministers. His father was settled over a Boston congregation: an able preacher and an accomplished man of letters. His mother was a woman of high qualities, and dignified bearing; his aunt, Mary Moody Emerson, who influenced him very strongly, was a strikingly original and a very cultivated woman. He was the third of seven children; two of his brothers, Edward and Charles, were distinguished for ability, but both died before middle age. His birthplace was within a few minutes' walk of that of 'the great Bostonian,' Benjamin Franklin. His father died when he was six years old, leaving his family in a straitened condition. At eight years old he entered the public grammar-school, and soon afterwards the Latin school. At the age of ten or eleven he was turning Virgil into English heroic verse, was fond of reading history, loved the study of Greek, and was given to frequent rhyming. He thinks the idle books under the bench at the Latin school were as profitable to him as the regular studies. One of his early schoolmates remembered him as 'a spiritual-looking boy in blue nankeens,' whom he loved when he looked upon him, he thought him 'so angelic and remarkable.'

Emerson did not take a very high rank in his college class, that which graduated at Harvard in 1821. He took a second prize, however, for an essay in English, and was chosen class poet after several others had declined. His college career had nothing of the singular brilliancy which characterised that of his brothers Edward and Charles. After graduating he kept school in different places, at the same time studying divinity under the direction of Dr Channing, and attending some of the lectures given at the Harvard Divinity School, the chief Unitarian theological seminary. He was grave, gentle, dignified as a teacher, never punishing except by words. He used to give the boys selections for reading,—something from Plutarch's *Lives*, for instance—to carry home with them. In 1826 he was 'appointed to preach' by the Middlesex Association of Ministers, and after preaching in several pulpits—at the south, where he was obliged to go for his health, at New Bedford, at Northampton—he was, on the 11th of March 1829, settled as colleague with the Rev. Henry Ware, minister of the Second Church in Boston. In September of the same year he was married to Miss Ellen Louisa Tucker, who died, without leaving any children, in 1832. In this same year he preached a sermon in which he announced certain views with regard to the Lord's Supper which were disapproved by the larger part of his congregation. This sermon is the only one of his ever printed. In consequence of the difference of opinion between himself and his parishioners, he found it impossible to continue in the relation which had been harmonious and happy, and thus, with the most friendly feelings on both sides, he left the pulpit of the Second Church, and found himself obliged to make a beginning in a new career.

In 1833 he made a first visit to Europe, of which he has given a brief account in the work entitled *English Traits*. On his return he preached in different pulpits, and began devoting himself to delivering lectures and writing essays. His first

subjects were 'Water' and 'Relation of Man to the Globe'—hardly such as we should have expected from the spiritual philosopher and poet, his acquaintance with the physical sciences being apparently very limited. But he wished to make good the loss of his salary, and lectured on branches of knowledge in which he knew he could interest the public. After a short experience he ventured on subjects more congenial to his past studies and habits of thought—Michael Angelo, Milton, Luther, George Fox, and Edmund Burke. In 1834 Emerson fixed his residence at Concord, a pleasant farming town in Middlesex county, Massachusetts, famous for having been the scene of the opening conflict of the revolution. He lived at first in an old 'gambrel-roofed' house built by his grandfather, the Rev. William Emerson, and afterwards celebrated as the 'Old Manse' of one of Hawthorne's stories, and the place where for a time he resided. In 1835 he married his second wife, Miss Lydia Jackson of Plymouth, Massachusetts. After this marriage, Mr and Mrs Emerson removed to the house which he purchased, where he passed the rest of his days. His widow, born 1802, died 13th November 1892.

During several successive years he delivered courses of lectures in Boston; in 1835 ten lectures on English literature, in 1836 twelve lectures on the philosophy of history, in 1837 ten lectures on human culture.

Emerson made the personal acquaintance of Carlyle during his first visit to Europe in 1833. Carlyle was then living at Craigenputtock, where Emerson sought him out, and passed time enough with him for some conversation, of which he has given an account in the first chapter of *English Traits*. In the next year, 1834, a letter from Emerson to Carlyle began a correspondence which continued nearly forty years, closing with the letter from Carlyle to Emerson, dated April 2, 1872. This correspondence, which has been carefully edited by Professor Charles Eliot Norton, shows the two men with all their characteristics; different as optimist and pessimist, yet with many profound sympathies with each other. Emerson was very desirous of having Carlyle come to stay with him at Concord. It would have been a dangerous experiment in vital chemistry—hydrofluoric acid in a vessel of glass. The deaths of Emerson's younger brothers, Edward in 1834, and Charles in 1836, produced a very deep impression on his affectionate nature. He had a true admiration for both of them, which they well deserved. The youngest, Charles Chauncy Emerson, well remembered by the present writer, stands apart from all the young men he has known for the elevation and beauty of his intellect and character.

In 1836 a thin volume was published, entitled *Nature*, which, though appearing anonymously, was at once known as coming from Emerson. Like his early poems, it was read by few, understood by fewer still, little thought of or cared for by the general reading public, but made much of by a small circle of admirers. It is a kind of poetical rhapsody—prose with wings growing, but not strong enough to lift it into the atmosphere of rhythmical music. To those who like naturally, or have acquired the taste for, the Emersonian modes of thought and expression, it is fascinating. But it took twelve years to sell five hundred copies. The germs of many of Emerson's thoughts, afterwards expanded in his essays and poems, may be found in this dreamy little volume.

Nature was followed by 'The American Scholar,' an oration delivered before the Phi Beta Kappa Society of Harvard University. Few anniversary addresses have attracted so much attention. Mr Lowell says of it that 'its delivery was an event

without any former parallel in our literary annals, a scene to be always treasured in the memory for its picturesqueness and its inspiration.' This grand oration was our intellectual declaration of independence. The orator did not spare his fellow-countrymen. 'We have listened too much,' he says, 'to the courtly muses of Europe. The spirit of the American freeman is already suspected to be timid, imitative, tame. The scholar is decent, indolent, complacent.' The young men of promise, he says, are discouraged and disheartened. 'What is the remedy? If the single man plant himself indomitably on his instincts and there abide, the huge world will come round to him. Patience—patience; with the shades of all the good and great for company; and for solace the perspective of your own infinite life; and for work the study and the communication of principles, the making those instincts prevalent, the conversion of the world.'

These two publications, the first in the series of his collected works, strike the keynote of his philosophical, poetical, and moral teachings. The 'Address before the senior class in Divinity College, Cambridge, July 1838,' which follows them, defined his position in, or out of, the church in which he had been a minister. Two or three sentences will sufficiently show where he stood: 'One man was true to what is in you and me. He saw that God incarnates himself in man, and evermore goes forth to take possession of his world. He said in this jubilee of sublime emotion, "I am divine. Through me God acts; through me speaks." . . . There is no doctrine of the Reason which will bear to be taught by the Understanding. The Understanding caught this high chant from the poet's lips and said, in the next age, "This was Jehovah come down out of heaven. I will kill you if you say he was a man."' In its simplest and broadest statement this discourse was a plea for the individual consciousness as against all historical creeds, bibles, churches; for the soul of each man as the supreme judge in spiritual matters. The delivery and publication of this address produced a great sensation in the religious world, especially among the Unitarians. Professor Andrews Norton attacked Mr Emerson's position in an article entitled 'The Latest Form of Infidelity.' Much controversy followed, in which Emerson took no part. He was not in the habit of defending his oracular statements. Delphi is not given to argument and explanation.

Whosoever has read carefully and lovingly these three essays, *Nature*, the *Phi Beta Kappa Oration*, and the *Divinity School Address*, can almost say of Emerson what he makes the Sphinx say of herself:

Who telleth one of my meanings
Is master of all I am.

These three essays take up about one-third of the first volume of his collected works, which are eleven in all. The titles of these volumes are as follow: Vol. i. *Nature; Addresses and Lectures*; ii. and iii. *Essays*, first and second series; iv. *Representative Men*; v. *English Traits*; vi. *The Conduct of Life*; vii. *Society and Solitude*; viii. *Letters and Social Aims*; ix. *Poems*; x. *Lectures and Biographical Sketches*; xi. *Miscellaneous*. These titles, and the more special ones which are included within them, give a very imperfect and unsatisfying idea of the contents of the eleven volumes. If these were taken to pieces, and their leaves thrown into a basket or barrel and shaken up, they might be taken out and rearranged in a dozen different ways, and yet have cohesion enough to make almost as intelligible consecutive reading as they are in their present order. Their arrangement under their different heads is nearly as

arbitrary as that of certain stars which are grouped under the name of Corona, or Lyra, or Andromeda. His son, Dr Edward Emerson, gave this account of his way of building his lectures in a paper, to the reading of which I had the privilege of listening: 'All through his life he kept a journal. . . . This book, he said, was his "Savings Bank." The thoughts thus received and garnered in his journals were indexed, and a great many of them appeared in his published works. They were religiously set down just as they came, in no order except chronological, but later they were grouped, enlarged or pruned, illustrated, worked into a lecture or discourse, and after having in this capacity undergone repeated testing and rearranging, were finally carefully sifted and more rigidly pruned, and were printed as essays.'

We can easily understand that in adjusting his mosaic fragments to each other there are likely to be occasional misfits which puzzle weary eyes and brains. Still, there are subtle connections oftentimes in thoughts which at first sight seem unrelated, and the pious reader of Emerson will always find it worth while to seek for them, though some of them may be 'hard for the non-elect to understand.'

Emerson wrote occasionally in verse from his schooldays until he had reached the age which used to be known as 'the grand climacteric,' sixty-three. *Terminus*, which he read to his son in 1860, is, so far as I know, the last poem he wrote. It is a farewell to his literary life, though he made some efforts in after-years. His poems are to his prose what the corolla is to the calyx. Both spring from the same root; both are modifications of the same growth; the sepal often shows the delicacy and colour of the petal, and the petal often lapses into the homelier texture and complexion of the sepal. His poems are not and hardly can become popular; they are not meant to be liked by the many, but to be dearly loved and cherished by the few. Such poems as *The Problem*, *Fate*, and *Days*, once rightly read, are never forgotten. The influence of Marvell, of George Herbert, of the Persian poets, of whom he was very fond, may be frequently traced; but the writer he most reminds us of, whatever he writes, is—Emerson. His occasional lawlessness in technical construction, his sometimes fantastic expressions, his enigmatic obscurities hardly detract from the pleasant surprise his verses so often bring with them. His teachings have not always had a wholesome effect on his train of imitators and followers in poetry, or what was meant for poetry. It was very well for him to find fault with 'the tinkle of piano-strings,' and say that

The kingly bard
Must strike the strings rudely and hard
As with hammer or with mace;

but if a self-crowned 'kingly bard' undertakes to play on the harp or piano with his fists instead of his fingers, we must beg leave to stop our ears. The magnificent lawlessness of 'Lord' Timothy Dexter in punctuation is a bad precedent for poets to follow in composition. The poetic license which we allow in the verse of Emerson is more than excused by the noble spirit which makes us forget its occasional blemishes, sometimes to be pleased with them as characteristic of the writer.

The idealist in philosophy, the rationalist in religion, the bold advocate of spiritual independence, of intuition as a divine guidance, of instinct as a heaven-born impulse, of individualism in its fullest extent, making each life a kind of theocratic egoism; all this may be seen in every one of his larger utterances. For him nature is a sphinx, written all over with hieroglyphics for which the spirit of man is to find the key. To interpret

nature is the province of the thinker, and especially of the poet—not as Bacon intends, by the analysis of phenomena—'natural philosophy'—but by detecting the higher, hidden significance of all natural appearances. He had learned from his wise relative, Aunt Mary Moody Emerson, to 'scorn trifles;' he bettered his lesson by teaching that man is made to scorn heaven itself if a higher empyrean is offered to him.

The fiend that man harries
Is love of the Best . . .
The heaven that now draws him
With sweetness untold
Once found—for new heavens
He spurneth the old.

Throughout his lectures and essays are scattered wise sayings, shrewd observations, delicate strokes of wit, curious gleanings from his widely discursive reading, and eloquent imaginative passages. But above all the special virtues to be found in his writings in prose and in verse we must recognise the sense of being in relation with a pure and lofty spiritual nature. 'Love of the Best' breathes in every expression of his thought. His writings must be read for their inspiring influence, their stimulus to high thought and endeavour, the noble manhood which pervades them. Recognising these as the chief claims of Emerson's essays and poems, we can delight in their singular and distinctive beauty of expression, their delicate wit, their iridescent variety of unexpected suggestions, their unaffected and often unconscious archaisms, which carry the reader's imagination back to his favourite Montaigne, their happy illustrations, their self-sustaining wisdom.

Emerson loved his quiet Concord life, the repose of which was, however, constantly broken by more or less welcome visitors, who sought him as an oracle. He was long-suffering with those 'devastators of the day,' as he called them, each of whom thinks of himself or herself as a privileged intruder. He travelled far and wide as a lecturer. In *English Traits* he has recorded not so much what he saw as what he thought while visiting England and Scotland, and in reflecting on his tour after his return. At home he was, according to village evidence, 'a first-rate neighbour, and one who always kept his fences up.'

Emerson was strongly opposed to slavery, but not conspicuous as an abolitionist. He would have bought out the slave-holders, and if men did not cling closer to their money than they do to their lives, his idea might have had some reason in it. He looked on at the 'Brook Farm' experiment with a kind of amused interest, but took no active part in the project. He listened to the long-haired reformers who swarmed at one time about the Chardon Street Chapel with a kindly curiosity, but his sense of humour as well as his good judgment was his safeguard, and he was not to be betrayed into any fanatical extravagance.

His personal appearance was that of the typical New Englander of college-bred ancestry. Tall, spare, slender, with sloping shoulders, slightly stooping in his later years, with light hair and eyes, the scholar's complexion, the prominent, somewhat arched nose which belongs to many of the New England sub-species, thin lips, suggestive of delicacy, but having nothing like primness, still less of the rigidity which is often noticeable in the generation succeeding next to that of the men in their shirt-sleeves, he would have been noticed anywhere as one evidently a scholarly thinker astray from the alcove or the study, which were his natural habitats. His voice was very sweet, and penetrating without any loudness or mark of effort. His enunciation was beautifully clear, but he often hesitated as if waiting for the right word to present

itself. His manner was very quiet, his smile was pleasant, but he did not like explosive laughter any better than Hawthorne did. None who met him can fail to recall that serene and kindly presence, in which there was mingled a certain spiritual remoteness with the most benignant human welcome to all who were privileged to enjoy his companionship.

The above article was by Oliver Wendell Holmes, who wrote also the great Life in 'The American Men of Letters Series' (1885). See also the authorised *Memoir of Ralph Waldo Emerson*, by James Elliot Cabot (1887); *Ralph Waldo Emerson, Life, Writings, and Philosophy*, by G. W. Cooke (1882); *Emerson at Home and Abroad*, by Moncure Daniel Conway (1882); *Emerson in Concord*, by his son Edward Waldo Emerson; and books by Alex. Ireland (1882), A. B. Alcott (1882), Joel Renton (1883), F. B. Sanborn (1885), R. Garnett (1888), Eliz. L. Carey (1904), Woodberry (1907), Perris (1910). His *Journals* from 1820 to 1873 were published in ten volumes in 1910-14. There is a standard edition of his works, edited by J. E. Cabot ('Riverside' edition, Boston, 11 vols. 1883-84); that with preface by Lord Morley (Macmillan, 6 vols. 1883-84); and one edited by Sampson (5 vols. 1906); and the 'Centenary' edition in 12 vols. (Constable, 1906).

Emery, the 'Armenian whetstone' of Theophrastus, is a variety of Corundum (q.v.), the mineral species which embraces ruby, sapphire, and other oriental precious stones, variously named according to their colour. The precious stones mentioned consist of nearly pure alumina in a crystalline condition, while emery is an amorphous admixture of alumina with varying proportions of oxide of iron and silica. Next to the diamond, these minerals are the hardest substances found in nature; but the hardness of emery is modified by the amount of iron and silica which enter into its composition. In external appearance emery has nothing in common with the brilliant stones to which it is related, being a dense, opaque, dull, bluish-black substance, like a fine-grained iron ore. It occurs in large boulder-like masses on Naxos and elsewhere in the Greek Archipelago, near Ephesus, and at Westchester, New York. (Carboidundum, a substitute, is made of carbon and silicon.)

It is prepared for use by first breaking it into lumps about the size of a hen's egg, then crushing these to powder by stampers. It is then sifted to various degrees of fineness, which are numbered according to the meshes of the sieve. Plate-glass manufacturers and others separate emery-powder into different degrees of fineness by the method of Elutriation (q.v.). Emery thus prepared is used for a great many important purposes in the arts. Being next in hardness to diamond-dust and crystalline corundum, the lapidary uses it for cutting and polishing many kinds of stone. Glass stoppers of all kinds are ground into their fittings with it. Plate-glass is ground flat by its means; it is also used in glass-cutting, and in grinding some kinds of metallic fittings. When employed for the polishing of metals, it has to be spread on some kind of surface to form a sort of fine file. *Emery-paper*, *emery-cloth*, *emery-sticks*, *emery-cake*, and *emery-stone* are various contrivances for such purposes. Emery-wheels are also largely used for smoothing and polishing the surface of iron castings, and in engineering work generally. These wheels consist principally of a mixture of emery-powder and hard vulcanised india-rubber. The polishing and buffing wheels employed by cutlers are also fed with emery-powder. See **POLISHING**.

Emesa. See **HEMS**.

Emetics, medicines given for the purpose of producing Vomiting (q.v.). They are given when it is desirable to relieve the stomach of some noxious or indigestible substance, such as a narcotic poison, or excess of food, or some special article of

diet which has disagreed. In diseases of the respiratory organs, emetics are given as the quickest and safest method of removing accumulated mucus from the air-passages; and in Croup (q.v.) their action is especially favourable, being often followed by expectoration and a rapid improvement in the suffocative symptoms. Emetics are to be given with great caution, however, in all very depressed states of the system, as their primary action is to produce nausea, which is attended always with more or less diminution of the vital power, and often with great depression of the heart's action, amounting to syncope or fainting. Emetics may produce vomiting either by their local action on the throat, gullet, and stomach, or by their action through the blood on the nervous mechanism regulating the movements of the stomach. They are thus divided into two groups, *local* and *general* emetics; and the depressing effect of the former is much less than that of the latter. Some substances will produce vomiting in either way; so that the distinction between the two classes is not very definite. Among the chief emetics in use are mustard (two tablespoonfuls), common salt (a tablespoonful or more), alum (a teaspoonful), in a tumblerful of water, repeated after a quarter of an hour if necessary. These, with sulphate of copper or zinc, are mainly local in their action, ipecacuanha and emetin, squills, senega, tartar emetic and other soluble salts of antimony, apomorphia, are mainly general in their action. The production of vomiting is aided, whatever emetic is used, by copious draughts of warm water. Tickling the throat with a finger or feather is often an effective mechanical means to produce vomiting.

Emetin is the alkaloid which forms the active principle of ipecacuanha-root. It may be obtained by drying the powdered root-bark with milk of lime, and then exhausting with boiling chloroform. It is a white powder, becoming brown on exposure to light, slightly soluble in water, but readily in alcohol. When taken internally it exhibits violent emetic properties, $\frac{1}{16}$ th of a grain sufficing to cause vomiting. The wood of the root contains no emetin; the virtue is in the bark. Emetin has been much used in dysentery and other diseases.

Emeu. See **EMU**.

Emigration in its established signification implies (1) permanently leaving a place to make a home elsewhere; (2) going out of one country to another, and generally to a distant part of the world; (3) going out from a community and leaving the bulk behind—in this sense the word is opposed to migration, which implies the movement of whole tribes or nations; (4) going out spontaneously, not as part of some systematic scheme of settlement—in this sense the word has been sometimes opposed to colonisation. In the country which people leave they are called emigrants or wanderers out; in that in which they settle they are called immigrants.

Among the principal causes may be noticed the pursuit of wealth, the pressure of population at home, and political, social, or religious discontent. The Spaniards went to America to get gold. Many of the Greeks in old times, like many of the English in our own, emigrated because of over-population. Political and social discontent, as well as over-population, accounts in great measure for the large numbers of Irish emigrants. The burden of compulsory military service is supposed to have been one determining cause of German emigration. And religious oppression led to the emigration of the Huguenots from France to England, and of the Puritans from England to North America.

In ancient times, when the Mediterranean was the centre of the world, the Greek race sent out

most emigrants and colonists. The Phœnicians were rather traders than settlers, and the Roman colonies were mainly military stations, carefully designed by government. The Greeks settled along the shores of the Mediterranean, from Cyprus to Marseilles, and their settlements were quite independent of, and in many cases greater than, the mother-cities.

Between ancient and modern times there intervenes a long period, during which there was a perpetual ebb and flow of races throughout Europe; but the movements of the barbarians who overran the provinces of the Roman empire, and even the later and more organised enterprises of such peoples as the Normans, fall rather under the head of migration, invasion, or conquest than under that of emigration. At the end of the 15th century, the discoveries of Vasco da Gama and Columbus disclosed new lands to which Europeans might emigrate, and stimulated the restless spirit which prompts to emigration. The Spaniards went to the west, the Portuguese to the east; and, being natives of the south of Europe, they were better fitted than the more northerly nations to make their homes in hot climates. Large numbers of Spaniards emigrated to the West Indies and to Central and South America. The Portuguese were fewer in numbers, and the East Indies, to which at first they chiefly went, were less suitable than America for European settlement; still, at the present day, their descendants are left in India, Ceylon, and elsewhere. To Brazil, which was outside their beat, they found their way by accident, and that country became the home of many Portuguese. Among the nations who followed the Portuguese and Spaniards to the east and west were the Dutch, the French, and the English. The Dutch, though great traders, did not send out many emigrants compared with other colonising peoples; but in addition to those who were attracted to the East Indies by commerce, Dutchmen emigrated to what is now known as New York, and still more to the Cape of Good Hope. The French were rather conquerors than settlers, but many Frenchmen emigrated to various parts of the world, as to the islands of Mauritius and Bourbon, to some of the West Indian islands, to Louisiana, and notably to Canada, where their descendants are now multiplying very fast. The English emigrated principally to the West Indies, to North America, and later to Australasia and South Africa.

European emigration increased by leaps and bounds in the 19th century, because the population of Europe had increased so enormously. It is obvious that the favourite fields for European emigration must be (a) countries with a suitable—i.e. a temperate—climate; (b) countries which have not an over-large population already; (c) countries which have large resources—i.e. large facilities for making wealth. Tried by these tests, it is clear that, as has actually been the case, the United States and British North America, Australia, New Zealand, South Africa (though there the native population is large), and the more temperate parts of South America—e.g. the Argentine Republic—would be the places which would attract most emigrants. The Teutonic nations have supplied the largest number, including English, Germans, and Scandinavians. The Germans have gone in great measure to the north central districts of the United States, the Swedes to Minnesota and Canada. Of the Celtic peoples the Irish have emigrated in largest numbers, mainly to the United States. In New York city the Irish element is exceptionally large. France sends out few emigrants; but there is a large stream of Italians to the Argentine Republic.

There are always many persons of an ambitious

or roving disposition who will emigrate; but emigration is not suitable for all, and those who are in good situations will do well as a rule to stop at home. Emigration was called by J. S. Mill 'the safety-valve of the labour-market'; but it does not consist in sending all the most skilful workmen out of the country, for these, generally speaking, can get work here, and have therefore less inducement to emigrate. It appeals more strongly to that vast body of ordinary men and women who are crowded out by competition, or who want to give their children better chances than they had themselves. Paupers, criminals, or other undesirable persons are prevented from landing by numerous Immigration Restriction Acts; but thousands of suitable persons have emigrated to the advantage of themselves and the country of their choice. The capital which they take with them is not wholly lost by the mother-country, for every settler in the dominions overseas buys much home produce; and many millions of pounds have been sent back by them to help friends and relations at home. See COLONY, COOLIES, IMMIGRATION.

Émigrés, the name given more especially to those persons who quitted France during the Revolution. After the insurrection at Paris, and the taking of the Bastille, 14th July 1789, the princes of the royal family departed from France. They were followed, after the adoption of the constitution of 1791, by all who considered themselves aggrieved by the destruction of their privileges, or who were exposed to persecution. Nobles quitted their châteaux; officers, with whole companies, passed the frontiers. Crowds of priests and monks fled to escape the oath of allegiance to the constitution. Belgium, Piedmont, Holland, Switzerland, and, above all, Germany, were overrun with fugitives of every age. Only a few had been able to save their property; the greater portion were in a state of destitution, and sank into utter demoralisation. A court had formed itself round the princes at Coblenz; a government, with ministers and a court of justice, had been established, and communication was kept up with all the foreign courts unfavourable to the Revolution. This conduct embittered France, aggravated the position of the king, and drove the revolutionary party forward in their sanguinary career. Under the command of the Prince of Condé, a body of émigrés was formed, which followed the Prussian army into Champagne. The result was that the severest laws were now put in force against the émigrés; their lands were confiscated; the penalty of death was proclaimed against any one who should support or enter into communication with them; thirty thousand persons were placed upon the list of émigrés, and exiled for ever from the soil of France, although many of them had refused to bear arms against their country. Not until after the failure of their attempt to land at Quiberon in 1795 did the émigrés abandon all thoughts of penetrating into France by force of arms. Condé's corps, after the peace of Lunéville, was obliged formally to dissolve, and sought an asylum in Russia. Even under the Directory, however, many had endeavoured to obtain permission to return to France. The general amnesty proclaimed by the First Consul was therefore joyfully hailed by the greater portion of the émigrés, though many did not return home till after the downfall of Napoleon. Dignities, pensions, and offices were now showered upon these faithful adherents; but, according to the charter of 1814, they were unable to recover either their estates or their privileges. Finally, on the motion of the minister Villèle, the émigrés who had lost their landed estates received, by the law of the 27th April 1825, a compensation of 30 million francs yearly on the capital of 1000 million francs. After

the July revolution the grant was withdrawn. See Saint-Gervais, *Histoire des Émigrés Français* (1823); a book by Lebon (1882); but especially E. Daudet, *L'Histoire de l'Émigration Française* (3 vols. 1886-89).

Emilia, a name now employed to designate a compartimento of Central Italy, comprising the provinces of Bologna, Ferrara, Forlì, Modena, Parma, Piacenza, Ravenna, and Reggio Emilia. The name is derived from the ancient *Via Emilia* (a continuation of the *Via Flaminia*, or great northern road), which passed through these territories. See ITALY.

Eminence, a title given by Urban VIII., in 1631, to cardinals, who up to the period of his pontificate had been called Most Illustrious.

Eminent Domain, a phrase which occurs more commonly in its Latin form, *dominium emans*, denotes the universal right in the public over property, by virtue of which the supreme authority in a state may compel a proprietor to part with what is his own for the public use. Thus a private owner may be compelled to give up part of his land that a public highway may be made through his ground. For the just exercise of this right there must be a necessity or clear public utility in the work proposed; and the expropriated owner must be compensated for his loss. The right is now exercised only under well-defined statutory regulations, such as the Lands Clauses Consolidation Acts, which regulate the purchase of lands for railways and other public undertakings.

Emin Pasha. See SCHNITZER (EDUARD).

Emir (plur. *Omrah*), an Arabic word, equivalent to 'ruler,' is a title given in the East, and in the North of Africa, to all independent chieftains, and also to all the actual or supposed descendants of Mohammed through his daughter Fatima. The latter are very numerous throughout the Turkish dominions, but, although entitled by birth to be classed among the first of the four orders of society, they enjoy no particular privileges or consideration, and are found engaged in all sorts of occupations. Their privileges are confined to a few unimportant matters, chiefly to the exclusive right to wear turbans of a green colour, that having been the favourite colour of the Prophet. They are placed under the supervision of the Emir-Beshir. The title Emir, in connection with other words, likewise designates different offices. *Emir-el-Mumenin*, 'Prince of the Faithful,' was the title assumed by the khalifs themselves, while *Emir-al-Omrah*, 'Prince of Princes,' was the title of their first minister. The Turkish master of the horse was styled *Emir-Achor*; the standard-bearer, *Emir-Alem*; and the leader of the caravans of pilgrims to Mecca, *Emir-Hadjî*. *Amir*, *Ameer*, and *Amere* are other spellings of the same word. Admiral (q.v.) is a derivative.

Emission Theory. See LIGHT.

Emmanuel, or IMMANUEL (Heb., 'God with us'), was the symbolical name of the child announced by Isaiah to Ahaz and the nation (Isa. vii. 14), and applied by St Matthew to the Messiah born of the Virgin (Matt. i. 23).

Emmaus, a village of Judea, not far from Jerusalem (Luke, xxiv. 13), which after the Jewish war was colonised with 800 Roman veterans. A writer in the quarterly statement of the Palestine Exploration Fund (January 1883) identifies it with the valley of the Urtas, 7 miles from Jerusalem, and south of Bethlehem, where costly baths have been discovered.

Emmenagogues, medicines intended to restore, or to bring on for the first time, the menses in women. See MENSTRUATION.

Emmerich, an old walled town of Rheinland, on the Rhine, near the borders of Holland, 94 miles by rail E. of Rotterdam. It has manufac-

tures of iron, glass, tobacco, &c., besides an active river trade. From a small Roman colony the town grew in importance until, in the 15th century, it had 40,000 inhabitants; from 1592 to 1811 it was the seat of a famous Jesuit seminary. Pop. 13,000.

Emmet, ROBERT, an ill-fated Irish patriot, was born in Dublin in 1778, the youngest son of the physician to the viceroy. At fifteen he entered Trinity College, where Moore was a fellow-student, but an academic career of exceptional promise was soon cut short by his joining the United Irishmen. He next travelled on the Continent, interviewed Napoleon and Talleyrand in 1802 on behalf of the Irish cause, and returned the next year to devote his own fortune of £3000 to buying muskets and manufacturing pikes. With a few confederates he laid a plot to seize Dublin Castle, and secure the person of the viceroy, but the rising proved a complete failure, and Emmet, who had arrayed himself for the occasion in a green coat, white breeches, and cocked hat, had the mortification to see nothing result from his enterprise but a few ruffianly murders. He escaped to the Wicklow Mountains, but returning for a last interview with his sweetheart, Sarah Curran (q.v.), the daughter of the orator, was arrested, put on trial on 19th September 1803, condemned to death, and hanged the following day. Just before receiving sentence he delivered a speech which still thrills the reader.—His elder brother, THOMAS ADDIS EMMET (1764-1827), a Dublin barrister, was counsel for the United Irishmen, was imprisoned and exiled, and became Attorney-general of New York State.

Emollients (from Lat. *mollis*, 'soft'), substances used to soften the textures to which they are applied, as poultices, fomentations, &c., externally, and Demulcents (q.v.) internally.

Emotion, a word used in philosophy with some considerable variety of meaning. The phenomena of the mind may be divided into three groups—cognitions, emotions, and volitions, into intellect or thought, feeling, and will. The emotions taken in this sense constitute one of the great groups of mental activities. They may be pleasurable, painful, or neutral, and may be arranged according as they arise directly out of the senses, movements, and appetites or not. In the latter case they comprise feelings of freedom and restraint, wonder, terror, love, self-complacency, the sense of power, anger, love of knowledge, artistic emotions, the moral sense, &c. As they combine and pass into one another by infinite gradations, a systematic and exhaustive classification is impossible. Sometimes emotion implies that the feeling is keenly experienced, so as to occasion mental disturbance. The expression of the emotions, especially in the face, was carefully studied by Sir Charles Bell; and Darwin's *Expression of the Emotions in Man and Animals* (1873) is a monument of patient observation and insight. The emotions act powerfully on the organic functions of the body, as illustrated in blushing, quicker or slower pulsation of the heart, cold perspiration, &c. The term *feeling* is used with even greater laxity than emotion. It is sometimes the perception we have of extreme objects, of their being hard or soft, hot or cold, in which case it is the intellectual function of sensation, or the sensation itself. Again, it may be specifically pleasure, pain, or the neutral emotion, or emotion in the widest sense. Or it may be used loosely for almost any kind of consciousness, as by James Mill. The higher feelings, as the appreciation of the sublime and beautiful, approval and disapproval, are often termed sentiments. See the article PSYCHOLOGY, and the list of works there cited.

Empecinado, DON JUAN MARTIN DIAZ, EL, one of the leaders of the Spanish revolution of 1820, was born in 1775, and entered the Spanish army in 1792. He carried on a guerilla warfare against the French during the Peninsular struggle, and acquired great distinction. In 1814 he was appointed colonel in the regular army, and the king himself created him *marchal-de-camp*; but in consequence of petitioning Ferdinand, in 1815, to reinstitute the Cortes, he was banished to Valladolid. On the outbreak of the insurrection in 1820 he took a prominent part on the side of the constitutionalists; after the triumph of the absolutists in 1823 he was arrested, exposed in an iron cage to the contumely of the passers-by, and finally, while struggling with his executioners, stabbed by one of the soldiers.

Empedocles, a Greek philosopher of Agrigento, in Sicily, lived about 450 B.C. So great was the estimation in which he was held by his fellow-citizens as a physician, a friend of the gods, a predictor of futurity, and a magician, that they are said to have offered him the sovereignty. But being an enemy of tyranny, he declined it, and was the means of delivering the community from the dominion of the aristocracy, and bringing in a democracy. There was a tradition that he threw himself into the crater of Etna in order that his sudden disappearance might beget a belief in his divine origin; this, however, can only be regarded as a mere fable, like the story told by Lucian, that Etna threw out the sandals of the vain philosopher, and thus destroyed the popular belief in his divinity. In Matthew Arnold's poem, *Empedocles on Etna*, the philosopher is represented as superior to vanity and superstition, but moody and out of sympathy with his contemporaries.

In Empedocles philosophic thought is bound up with poetry and myth even more closely than in Parmenides (q.v.). His general point of view is determined by the influence of the Eleatic school upon the physical theories of the Ionic philosophers. He assumed four primitive independent substances—air, water, fire, and earth, which he designates often by the mythical names Zeus, Hera, &c. These four elements, as they were called, kept their place till modern chemistry dislodged them. Along with material elements he affirmed the existence of two moving and operating powers, love and hate, or affinity and antipathy, the first as the uniting principle, the second as the separating. The contrast between matter and power, or force, is thus brought out more strongly by Empedocles than by previous philosophers. His theory of the universe seems to assume a gradual development of the perfect out of the imperfect, and a periodical return of things to the elemental state, in order to be again separated, and a new world of phenomena formed. Of his opinions on special phenomena may be mentioned his doctrine of emanations, by which, in connection with the maxim that like is known only by like, he thought to explain the nature of perception by the senses. He attempted to give a moral application to the old doctrine of the transmigration of souls, his views of which resembled those of Pythagoras.

The fragments of Empedocles were edited by Karsten (1838) and Stein (1852). See Zeller's *Greek Philosophy* (trans. 1881), Benn's *Greek Philosophers* (1882), and Gomperz's *Greek Thinkers* (4 vols. 1901-13).

Emperor (Lat. *imperator*), a title formerly borne by the heads of the Roman empire, which in the modern world became the highest title of sovereignty. In Rome the *imperium* of a magistrate, whether king or consul, was the power which he possessed of bringing physical force into operation for the fulfilment of his behests. This power was conferred by a *lex curiata*, and it required this authorisation to entitle a consul to

act as the commander of an army. In the case of the kings also the *imperium* was not implied in their election, but was conferred separately, by a distinct act of the national will. Now it was in virtue of this *imperium* that the title *imperator* was given to its possessor. Far from being an emperor in the modern sense, he might be a consul or a proconsul; and there were, in fact, many *imperatores*, even after the title had been assumed as a praenomen by Julius Caesar. It was this assumption which gradually gave to the title its modern signification. In republican times it had followed the name, and indicated simply that its possessor was an *imperator*, or one possessed of the *imperium*; now it preceded it (see *CÆSAR*), and signified that he who arrogated it to himself was the emperor. Nor was it, as has often been mistakenly asserted, merely a military command; it included also the supreme judicial and consequently also the administrative power; and under the empire the office was free from the temporal and local limitations which had accompanied its enjoyment during the republic. From the emperors of the West the title passed to Charlemagne, the founder of the Holy Roman Empire. When the Carolingian family expired in the German branch, the imperial crown became elective, and continued to be so until, in 1806, Francis II. resigned the title, and withdrew to the government of his hereditary dominions, under the title, assumed in 1805, of Emperor of Austria. The title of *imperator*, like that of *basileus* (Gr., 'king'), was frequently assumed in England by the Anglo-Saxon monarchs. Henry VIII.'s parliament in 1532, abolishing appeals to Rome, declared that 'this realm of England is an empire;' Spenser's *Faerie Queene* was dedicated to the 'Empress Elizabeth, Queen of England, France, and Ireland, and of Virginia;' the prayer-book rubrics said James I. was 'endowed with a crown imperial.' The rulers of Abyssinia and Japan have been called emperors, as were those of Austria, Brazil, China, France, Germany, Hayti, Korea, Mexico, Morocco, Russia, and Turkey. See *BYZANTINE EMPIRE*, *CÆSAR*, *FRANCE*, *GERMANY*, *IMPERIALISM*, *INDIA*, *ROME*; Lord Cromer's *Ancient and Modern Imperialism* (1910), and Sir C. P. Lucas's *Greater Rome and Greater Britain* (1913).

Emperor Moth (*Saturnia carpinii*), nearly related to the silkworm moths (*Bombycina*). With the exception of the Death's Head, it is the largest

Emperor Moth, with Caterpillar, Pupa, and Cocoon.

British moth. Its expanse of wings is about three inches; the female is mainly gray, the male from reddish-brown to orange-yellow; each wing bears

a large black eye, with surrounding rings. The caterpillar is green, with short hair, black cross bands, and yellow or reddish tubercles. The cocoons are formed internally of stiff convergent elastic threads, which resist intrusion, but readily admit of egress. The Great Peacock Moth (*Saturnia pyri*) is a very large European form about twice the size of the Emperor. See SILK.

Emphysema, in Medicine, an unnatural distension of a part with air. Emphysema of the cellular texture is usually caused by a wound of the lungs or upper air-passages, from which air escapes during respiration into the cellular tissue. It may be confined to the immediate neighbourhood of the wound, or may extend all over the body. Emphysema is rarely produced otherwise than mechanically; but in gangrene and after death various bacteria may produce decomposition and give out gases, which penetrate and distend the tissues with which they are in contact.

Emphysema of the lungs is the name applied to two distinct conditions. (1) *Interlobular or cellular emphysema*, allied to the form described above in that it depends on a wound of the delicate lining-membrane, and that air occupies the interstices of the cellular tissue, is not common, and occurs only in childhood. (2) *Vesicular emphysema* consists in an unnatural distension of some of the natural air-cells or *vesicles* of the lungs, and is almost invariably present in those who have long suffered from chronic bronchitis or asthma, or have in any way been obliged to make excessive respiratory efforts—e.g. in the blowing of large wind-instruments. The walls of the affected vesicles become thinned, and may ultimately disappear between two or more in contact with each other, so that though the apparent size of the lung increases, the surface available for aeration of the blood is actually much diminished, and great shortness of breath results. The same process is common in the horse, and familiar under the name of 'broken wind.' The only treatment possible is that of the condition to which the emphysema is due; for the affected vesicles cannot be restored to their original condition.

Emphyteusis (Gr., 'implanting'), in Roman law, a perpetual right in a piece of land, for which a yearly sum was paid to the proprietor. It much resembled a feudal holding. See FEU, FEUDALISM.

Empiricism, the name applied to a school in philosophy which admits of nothing as true but what is the result of experience, rejecting all *a priori* knowledge. It arose out of the system of Heraclitus which is elaborately refuted in the *Theætetus* of Plato, and was abhorrent to the lofty idealism of Socrates. Aristotle was an empiricist in so far as experience (*empeiria*) was to him the realisation of the ideal or formal. The philosophy of Descartes established a kind of compromise between one part of knowledge regarded as innate, and another part as empirical or imparted from without. The founder of modern empiricism was Locke, who makes experience the basis of all knowledge, comprehending alike sensation and reflection. Condillac and the other French *philosophes*, rejecting reflection, pushed to an extreme the sensational side of Locke's philosophy, while Berkeley and Hume developed it on other lines to widely differing conclusions. The Common Sense school maintained that the ground of all knowledge was certain primary beliefs or first principles; Kant, on the other hand, found in the *a posteriori* facts of experience the first form of a consciousness which in its ultimate development must become *a priori*. The two elements are inseparably united; thus the *a posteriori* element, the facts, exist for us only under *a priori* conditions. This may almost be said to mark the turning-point of the new philo-

sophy which has demonstrated that the distinction itself is not absolute, or rather that the distinction is itself transcended in the essential unity of knowledge.

The name *empiric* is applied also to one who depends on the accumulations of experience in any branch of knowledge, as in medicine, rather than on the strictly scientific methods of inference and deduction. See, on the one hand, MEDICINE; and, on the other, QUACK DOCTORS.

The term *Empirical Laws* is applied to such as express relationships, which may be merely accidental, observed to subsist among phenomena, but which do not suggest or imply the explanation or cause of the production of the phenomena. They are usually tentative, and form stages in the progress of discovery of causal laws. Bode's law of the distances of the planets from the sun is an example.

Employers' Liability. See FACTORY ACTS, MASTER AND SERVANT.

Empoli, a town of Italy, in a beautiful and fertile district on the left bank of the Arno, by rail 22 miles WSW. of Florence and 27 E. of Pisa. The collegiate church (1093), with a fine original facade, though the rest of the building was considerably altered in 1738, contains some good paintings and sculpture. Pop. 22,000.

Emporia, capital of Lyon county, Kansas, on the Neosho, a tributary of the Cottonwood River, 61 miles SSW. of Topeka by rail. It has railway-shops and a college. Pop. 11,000.

Empson, SIR RICHARD, the unpopular agent of Henry VII., was the son of a wealthy citizen of Towcester, Northamptonshire, and was trained for the bar. In 1491 he became Speaker of the House of Commons, and in 1504, now a knight, High Steward of Cambridge University, and Chancellor of the Duchy of Lancaster. Throughout Henry's reign he was employed like Edmund Dudley (q.v.) in exacting taxes and penalties due to the crown. His conduct, defended by himself as strictly legal throughout, was by the people regarded as infamous and tyrannical, and in the second year of Henry VIII.'s reign he was convicted of tyrannising and of constructive treason, attainted, and beheaded on Tower Hill with his partner Dudley, 17th August 1510.

Emption. See SALE OF GOODS.

Empycma (Gr.), an internal suppuration, a word now applied exclusively to a collection of pus in the pleura. See PLEURISY.

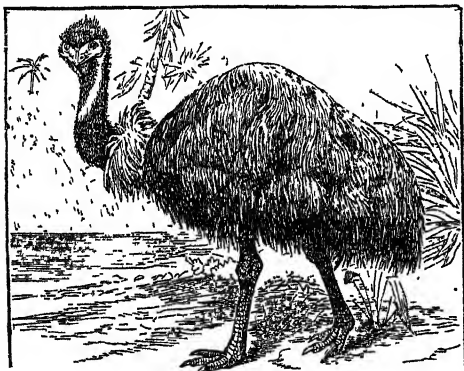

Empyrean, a word used by the old metaphysical natural philosophers to designate the highest region of light, where the purest and most rarified elements of fire (Gr. *pyr*) existed; and by medieval and modern poets to indicate heaven, the source of light and the home of the blessed.

Empyreuma (Gr. *empyreūō*, 'I kindle'), the burned smell and acid taste which result when vegetable or animal substances are decomposed by a strong heat. The cause of the smell and taste resides in an oil called *empyreumatic*, which does not exist naturally in the substance, but is formed by its decomposition.

Ems, a river in the north-west of Germany, rises in Westphalia, on the south-west slope of the Teutoburger Wald, flows first in a north-west and then through a moory region in a northern direction, and empties itself into Dollart Bay, an estuary of the German Ocean, after a course of 205 miles. It is navigable as far as Greven (139 miles). In 1818 it was connected by a canal with the Lippe, and thus with the Rhine. A canal uniting the Ems with the Jade was made in 1890, and one connecting the Ems with Dortmund in 1896.

Ems, or BAD EMS, a bathing-place known to the Romans, and celebrated in Germany as early as the 14th century. It is situated on the river Lahn, 10 miles ESE. of Coblenz by rail. Pop. 7500, a number more than doubled by patients. Its warm mineral springs belong to the class containing soda; the only essential difference between the numerous springs is in the temperature, varying from 80° to 135° F., and in the greater or lesser amount of carbonic acid gas contained in them. Here in 1870 Benedetti got his final answer from King William.

Emu (*Dromæus*), a genus of running birds or Ratites in the cassowary family. There are two species, both Australian—viz. the Common Emu (*D. novæ hollandiæ*) and the Spotted Emu (*D. irroratus*). They differ from the Cassowaries (q.v.) in several marked features—e.g. the head and neck are feathered except on cheeks and throat, there is no 'helmet,' nor are there wattles on the neck, the bill is broad, and the claws of the three toes are almost of equal length. The emu is a large bird, standing about 6 feet in height. The plumage is like that of the cassowary; the colour is predominantly dull brown, darker on the head, neck, and middle line of the back, lighter beneath. The naked parts of head and neck are grayish-blue, the bill and feet brownish. The young are striped with black. The wings are of course rudimentary, but the legs serve the bird well both in running and kicking.

Common Emu (*Dromæus novæ hollandiæ*).

Timid and peaceful in character, the emu trusts to its speed for safety. It is valued on account of its beef-like flesh, abundant oil, and edible eggs, but is unfortunately being destroyed with too great carelessness. The plains of the interior are now the chief haunts; the food consists chiefly of roots, fruits, and herbage. The note is a curious booming sound. The emu is not polygamous like the Ostrich (q.v.); true pairing occurs. The eggs are placed in a scooped-out cavity in the earth; they have a dark-green shagreen appearance, and measure on an average 4 × 3½ inches. About forty are laid in a summer; the male incubates the first set, and is then relieved by the female, who has by that time finished her laying. The period of incubation is three months. The development was carefully studied by Haswell (Linn. Soc., N.S.W., 1887). The Spotted Emu, restricted to Western Australia, has often bred in captivity or attempted domestication in Britain and elsewhere. Emeu is an older spelling of the name.

Emulsin, or SYNAPTASE, is a peculiar ferment present in the bitter and sweet almond, which forms a constituent of all almond emulsions. When bitter almonds are bruised, and water added, the emulsin acts as a ferment on the amygdalin,

and decomposes the latter into volatile oil of bitter almonds, prussic acid, grape-sugar, and water (see ALMONDS, VOLATILE OIL). The vegetable albumen of almonds is almost entirely composed of emulsin, which, when separated, is a white substance, soluble in water, and is distinguished by its remarkable power of causing the fermentation of amygdalin. It consists of carbon, hydrogen, nitrogen, and oxygen.

Emulsion is the term applied to those preparations in pharmacy in which oleaginous substances are suspended in water by means of gum, sugar, carrageen, yolk of egg, &c. The production of these emulsions is often not an easy matter, and requires judgment and skill. In general it will be found that the bulk of the emulsifier must first be taken, while the oil should only be added little by little, rubbing together in a mortar, and taking care that it is completely absorbed or emulsified before further additions. Should too much be added, the effect is to throw out most of what has already been incorporated, and it is then almost impossible to remedy the error. The emulsion of cod-liver oil is probably known to all, but there are many emulsions in which solid substances have to be suspended, and to them the directions above given are not always applicable.

Emys, a genus of Marsh Tortoises, including *E. lutaria*, found in south and middle Europe, North Africa, and south-west Asia. The other species are oriental and American.

Enamel (Fr. *émaïl*; originally *esmail*, from the same root as *smelt*), the name given to vitrified substances applied chiefly to the surface of metals. Enamelling is practised (1) for purposes of utility, as in making the dial-plates of watches and clocks, coating the insides of culinary vessels, &c.; and (2) for producing artistic designs, portraits, and for ornamental purposes generally. The basis of all enamels is an easily fusible colourless glass, to which the desired colour and opacity are imparted by mixtures of metallic oxides. The mass, after being fused together and cooled, is reduced to a fine powder and washed, and the raw material thus obtained is variously applied to the surfaces to be covered according to the class of enamel being made. The whole is then exposed in a furnace (*fired*, as it is called) till the enamel is melted, when it adheres firmly to the metal. The metal most commonly used as a ground for enamel is copper; but for the finest kinds of enamel-work gold and silver are also used.

Artistic or Ornamental Enamelling.—This art is of great antiquity; it was to a limited extent practised by the Greeks; but enamels were more largely employed by the Romans, under whose dominion the art passed into Gaul and Britain. Enamelling has also been practised from a remote period in the East, Persia, India, China, and Japan, under a separate and distinct development; but there is nothing from which it can be inferred that the various methods were in use earlier than in Europe. As a decoration enamelling was more popular and attained to greater perfection in the middle ages than in classic times. It was extensively practised at Byzantium from the 4th until the 11th century, and afterwards in Italy, in the Rhenish provinces, and at Limoges in the south of France. The Byzantine and other early styles of enamel-work, down to the 14th century, were generally employed in ornamenting objects connected with the service of the church. Enamel was also greatly used in ornamenting jewelry, and vessels made for use or display in the mansions of the rich, such as salt-cellars, coffers, ewers, candlesticks, &c.; but these objects were principally made in the painted

enamels introduced in France towards the end of the 15th century.

Distinguished with reference to the manner of execution, enamel-work may be divided into four kinds: (1) *Cloisonné*, or inclosed, the method of the Byzantine school, in which the design is formed in a kind of metal case, generally gold or copper, and the several colours are separated by very delicate filigree gold bands, to prevent them running into one another. Of this style the grandest example extant is the famous *Pala d'oro* in St Mark's Church, Venice, some portions of which are Byzantine of the 10th century. (2) *Champlevé*, practised by the Rhenish and early Limoges schools. In this process the ornamental design, or the figures which were to be filled in with colour, were cut in the metal (generally copper) to some depth; and wherever two colours met, a thin partition of the metal was left to prevent the colours running into each other by fusion when fired. (3) Translucent enamel, which had its origin and was brought to great perfection in Italy, was composed of transparent enamel of every variety of colour, laid in thin coatings over the design, which was incised on the metal, generally silver, the figure or figures being slightly raised in low relief, and marked with the graver, so as to allow the drawing of the contours to be seen through the ground, instead of being formed by the coarse lines of the copper, as in the early Limoges enamels. (4) Surface-painted enamels, which may be divided into two stages. The first stage, which is known as the late Limoges style, sprang up about 1475, and flourished till 1630. In this the practice was to cover the metal plate with a coating of dark enamel for shadows, and to paint on this with white, sometimes having the hands and other parts of the figures completely coloured. The designs of the middle and best period were generally taken from well-known paintings or engravings of the period, and were strongly influenced by the Italian art of the time. This style soon degenerated, and gave place to the latest or *miniature* style, which was invented before the middle of the 16th century by Jean Toutin, a goldsmith at Châteaudun, and carried to the highest perfection by Jean Petitot, a miniature-painter, who was born at Geneva, 1607, and resided long in England, and then in Paris. On his method the plate is covered with a white opaque enamel, and the colours are laid on this with a hair-pencil, and fixed by firing. The paints are prepared by grinding up coloured enamels with oil of spike, and when fused by the heat, they become incorporated with the enamel of the ground. The earlier enamellers of this school occupied themselves with miniatures, snuff-boxes, watch-cases, and other trinkets, till the period of the Revolution, when the art fell into disuse in France. In England, however, it was carried on with much success; and copies of portraits and pictures on a much larger scale than the French miniatures were executed by Henry Bone (1755-1834), and the German, Karl Muss (died 1824). Works of this description possess the obvious advantage of durability; but those various qualities of texture, and the delicacy of colour for which good works in oil or water-colour are prized, cannot be attained in enamel copies. The greater part of the artistic enamel-work of the present day is of Japanese fabrication, and consists of cloisonné work on a copper basis. Both in Paris and in Birmingham enamel-work of this class has been attempted with success; but designs can be executed in Japan at prices which defy the competition of western traders. In China both cloisonné and painted enamels are made in characteristic Chinese designs. At Jeypore in India a limited quantity of enamel-

work on gold is executed in translucent colours which possess incomparable brilliancy. Enamel incrustations of various kinds are very largely used in the jewelry, goldsmith, and silversmith trades of Europe. See H. H. Cunynghame's *Enamelling on Metals* (2d ed. 1906) and *European Enamels*; A. Fisher's *Enamelling upon Metal* (1906); and for enamelled earthenware, see the article POTTERY.

Enamelled Iron.—Since the beginning of the 19th century many attempts have been made to cover iron with a vitreous surface, and several patents have been taken for such methods of enamelling. The chief difficulty in applying enamels to iron arises from the tendency of the metal to oxidise before it reaches the temperature at which the enamel fuses, and to become brittle from the oxide combining with the silica of the enamel. This action being superficial, the mischief is the greater in proportion to the thinness of the iron. Therefore it is much easier to enamel thick cast-iron vessels than thin vessels made of sheet-iron. A glass may be made by combining either silicic acid or boric acid with a base; the latter fuses at a lower temperature than the former, but the glass is much dearer and not so durable as the silica glass. The enamels used for coating iron consist of a mixture of silica and borax, with various basic substances, such as soda, oxide of tin, alumina, oxide of lead, &c. Lead is not, or ought not to be, used in the enamel for coating culinary vessels.

A great variety of articles, many of them beautifully decorated in colours, such as grate-fronts, clock-dials, panels of different kinds, sign-boards, tablets, and name-plates, are now executed in enamelled iron at a moderate cost. It is also applied to corrugated roofing. The effect of heat on enamelled iron especially is to expand the metal more than the enamel, and cause the latter to peel off. Acids find their way through minute invisible pores, which exist in the best enamel; and when once they reach the iron, they rapidly spread between it and the enamel, and undermine and strip it off. This kind of action is curiously shown by filling an enamelled vessel with a solution of sulphate of copper. The acid attacks the iron wherever pores exist, and little beads of metallic copper are deposited at all such spots; these beads go on growing until they are large enough to be very plainly seen. This is the severest test for trying the continuity of enamelled surfaces to which they can be subjected, as sulphate of copper will penetrate the glaze and body of ordinary earthenware.

The enamel of teeth is the very hard translucent white layer covering the working surfaces of the Dentine (q.v.) or ivory of the teeth of most mammals. See TEETH.

Enara, a lake in the extreme north of Finland, with an area of 550 sq. m. and numerous islands. It discharges into the Arctic Ocean.

Enarea, formerly a kingdom of Africa to the SW. of Shoa, but since the last decade of the 19th century a district or province of Abyssinia. It is a land of forest-clad hills, rising beyond 8000 feet, with their slopes covered with the wild coffee-plant.

Encania. See COMMEMORATION.

Encalada, MANUEL BLANCO (1790-1876), born in Buenos Aires, studied at Madrid and in the naval academy at Leon, and after deserting from the Spanish ranks, joined the Chilean revolutionary party, and served with distinction both in the artillery and in the navy. Appointed second to Lord Cochrane, he became rear-admiral in 1819, major-general of infantry in 1820, and in 1825 head of the army. He was for two months president

of the republic in 1826, governor of Valparaiso in 1847-52, and minister to France in 1853-58.

Encaustic. See MURAL DECORATION, TILES.

Enceinte. See FORTIFICATION.

Encephalartos. See CYCADS.

Encephalitis Lethargica, a rare disease characterised by a condition of profound physical and mental lethargy. Some degree of fever and constitutional disturbance is usually, but not invariably, present. The lethargic semi-conscious condition of the patient may last for days or for weeks, and is not infrequently fatal. The causation of the disease is unknown. No constant changes have been found in the brain in fatal cases. There is no specific treatment for the disease.

Encephalocoele, a tumour projecting through the skull in one of the parts where the bones are incomplete in infancy, and consisting of a protrusion of the membranes of the brain, containing a portion of brain itself. In *meningocele* the membranes only project. The most common situation of such tumours is in the middle line and at the back of the head. Surgical interference is scarcely ever justifiable, and all that can usually be done is to give uniform support to the tumour, and to defend it from injury.

Enchondroma is the term employed in Pathological Anatomy to signify an abnormal cartilaginous growth. These growths most commonly occur in connection with the bones, but they are not unfrequent in some of the glandular structures. See TUMOURS.

Encina, or ENZINA, JUAN DE LA, the founder of the secular drama in Spain, was born about 1469, not far from Salamanca, at the university of which town he was educated. He held successively the offices of secretary to the first Duke of Alva, musical director in Pope Leo X.'s chapel at Rome, and prior of Leon in Spain. He died at Salamanca in 1534. Besides his *Canconero*, a collection of poems which went through six editions between 1496 and 1516, he wrote in 1521 a poor poetical account of a pilgrimage which he made to Jerusalem two years previously. But his fame rests on the fact that he wrote fourteen dramatic poems (*Representaciones*), half of them of a religious cast, but the other half altogether secular, these last the first of the kind acted in Spain, in 1492. These pieces possess no great merit, being almost destitute of plot, and showing little dramatic structure or spirit. See the edition by Cañete and Baobieri (Madrid, 1891).

Encke, JOHANN FRANZ, astronomer, was born at Hamburg, September 23, 1791. After studying at Göttingen, he served, during the campaign of 1813-14, in the artillery of the Hanseatic legion, and in 1815 in the Prussian army, as lieutenant of artillery. On the establishment of peace he left the service, and became assistant, and afterwards principal astronomer, in the observatory of Seeberg, near Gotha. In 1825, chiefly at the instigation of Bessel, he was called to Berlin as secretary of the Academy of Sciences and director of the observatory. While at Gotha, the astronomical prize offered by Cotta was awarded to Encke by the judges Gauss and Olbers, for his determination of the orbit of the comet of 1680. This led him to solve another problem, which had been proposed along with the other—viz. the distance of the sun. The solution, by means of the two transits of Venus in 1761 and 1769, is published in two separate tracts (*Die Entfernung der Sonne*, Gotha, 1822-24). In 1819 he proved that the comet discovered by Pons, November 26, 1818, revolves in the hitherto incredibly short period of about 1200 days, and had been already observed in 1786, 1795, and 1805. It has since gone by

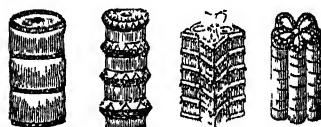

the name of Encke's comet, and has appeared regularly; the period of its recurrence being 3.29 years, or about $3\frac{1}{4}$ years (see COMET). Encke's researches on this subject are contained in the *Transactions of the Berlin Academy*. In 1830 he undertook to edit the *Berlin Astronomical Almanac*, in which he published a number of astronomical treatises (separately published, 3 vols. 1866). Four volumes appeared of his *Astronomical Observations at the Berlin Observatory* (1840-56). He died 2d September 1865. See his *Life* by Bruhns (Leip. 1869).

Enclosures. See COMMONS.

Encore ('again'), a French expression, generally used in England by the audience of a theatre or concert-room when requesting the repetition of the performance of a piece of music. It is not used by the French themselves, who, in similar circumstances, exclaim *bis* ('twice').

Encratites. See TATIAN.

Encrinurites, fossil Crinoids, often known as stone-lilies. They occur very abundantly, and

Encrinurus Stems (Mountain Limestone).

often seem as thick in a limestone or marble bed as straws in a corn-rick. See CRINOIDS.

Encrinurus, a genus of trilobites, of Ordovician and Silurian age.

Encumbered Estates Court, created in 1849 to facilitate the sale of encumbered estates in Ireland, and superseded by the Landed Estates Court in 1859, made 3457 sales, producing a sum of £25,190,839.

Encyclical (*literæ encyclicæ*), a letter addressed by the pope to all his bishops, condemning current errors or advising the Christian people how to act in regard to great public questions. It differs from a Bull (q.v.) mainly in that the latter is usually more special in its destination. The famous encyclical, *Quantum Curæ*, in 1864, by Pius IX., was accompanied by a *Syllabus* condemning specifically eighty errors in religion, philosophy, and politics. And its aim was revived in that issued by Pius X. in 1907 condemning 'Modernism,' and restoring Aquinas to sole and supreme authority.

Encyclopædia (from the Greek *enkyklios*, 'circular' or 'general,' and *paideia*, 'discipline' or 'instruction') is in modern usage a work professing to give information in regard to the whole circle of human knowledge, or in regard to everything included within some particular scientific or conventional division of it. The character of such works has of necessity varied from generation to generation, with changing conceptions of the scope and value of our knowledge and of the mutual relations of one department with another. An encyclopædia as such cannot rise above the general culture of its time; the medieval encyclopædia will be as medieval in the distribution and perspective of its subjects as in the selecting and presenting of its facts. As knowledge has increased it has become more and more necessary, in order to say something (and the most important something) about everything, to be content not to say everything about anything. And while, in the 10th century, one laborious student might undertake to give the world a conspectus of all that was of worth in its literature and science, a modern work of

similar scope demands the co-operation of hundreds of intellects. The word was first used in the sense of 'the circle of doctrine,' or learning (not a book), by Sir Thomas Elyot in *The Governour* (1531).

Though several of the ancient philosophers of Greece, and notably Aristotle, carried their investigations into every department of inquiry within their intellectual horizon, none of them seems to have compiled exactly what we now call an encyclopædia. Speusippus, indeed, is credited with something of the sort; but his works exist only in fragments. The great Latin collections of Terentius Varro (*Rerum humanarum et divinarum Antiquitates* and *Disciplinarum libri ix.*), dating from 30 B.C., and the so-called *Historia Naturalis* of the elder Pliny (23-79 A.D.), may thus be considered as the first specimens of their class. The 5th century saw the production of a curious and oddly written encyclopædia by Martianus Capella; in the 7th, Isidorus Hispalensis compiled his *Originum seu Etymologicarum libri xx*, which was afterwards abridged and recast by Hrabanus Maurus. Under the calif of Bagdad, Alfarabius or Farabi, in the 10th century, wrote an encyclopædic work, *Ihsa Atulum*—remarkable for its grasp and completeness; but this has hitherto been left in manuscript (a fine copy is preserved in the Escurial). Vincent of Beauvais (Vincentius Bellocacensis), who probably died in 1264, gathered together, under the patronage of Louis IX. of France, the entire knowledge of the middle ages in three comprehensive works—*Speculum Historiale*, *Speculum Naturale*, and *Speculum Doctrinale*, to which an unknown hand soon after added a *Speculum Morale*. About the same time Brunetto Latini was engaged on his *Livres dou Tresor* (printed in Italian in 1474, and in the original French in *Documents inédits*, 1860). The *De proprietatibus rerum* of Bartholomeus de Glanville deserves mention as being of English origin and highly successful in its day. Written about 1240, this became exceedingly popular in the translation (1398) by the Cornishman John Trevisa. In 1541 the name Cyclopædia is first used as the title of a book by Ringelberg of Basel, and in 1559 Paul Scalich styles his work *Encyclopædia seu orbis disciplinarum tum sacrarum tum profanarum*. Among the numerous encyclopædias of the 17th century it is enough to mention Antonio Zara's (Venice, 1615) and Alsted's (7 vols. fol. Heiborn, 1630), both in Latin; Moreri's *Grand Dictionnaire historique* (Lyons, 1674), which reached a 20th edition in 1759; Hofmann's *Lexicon Universale* (2 vols. fol. Basel, 1677; 4 vols. fol. Leyd. 1698), which was the first attempt to bring the whole body of science and art under the lexicographic form; Thomas Corneille's *Dictionnaire des Arts et des Sciences* (2 vols. Paris, 1694; and most famous of all, Bayle's *Dictionnaire historique et critique* (4 vols. Rotterdam, 1697), which was mainly designed as corrective and supplementary to Moreri. This last appeared in several English editions generally more or less expurgated or modified, as in that issued at London (10 vols. fol. 1734-41); and J. G. de Chauffepié published a *Nouveau Dictionnaire* as a supplement (4 vols. Amsterdam, 1750). It was in the course of the 17th century that encyclopedists began regularly to employ the vulgar tongues for their work, and to arrange their material alphabetically for convenience of consultation. Of the vast *Bibliotheca Universale*, planned by Coronelli to fill 45 folio volumes, only a small portion saw the light (Venice, 1701-6). The series of great encyclopædic works in modern English practically began by the anonymous *Universal, Historical, Geographical, Chronological, and Classical Dictionary* (2 vols. 1703), and the *Lexicon Technicum* of Dr John Harris (Lond. 1704). Ephraim Chambers followed in 1728 with his *Cyclo-*

pædia, or an *Universal Dictionary of Arts and Sciences* (2 vols. fol.), which presents a distinct advance in the construction of such works, the author endeavouring to give to his alphabetically arranged materials something of the interest of a continuous discourse by a system of cross references. A sixth edition of this popular work appeared in 1751-52, and a supplement in 2 fol. vols. in 1753. Dennis de Coetlogon published an *Universal History of Arts and Sciences* (2 vols. fol. Lond. 1745). A revised and enlarged edition of Chambers's was published in 1778-88 by Abraham Rees, who, besides incorporating the supplement with the main body of the work, added a large amount of original matter.

It was a French translation, by John Mills, of Chambers's *Cyclopædia* which originally formed the basis of that famous *Encyclopédie* which, becoming in the hands of D'Alembert and Diderot the organ of the most advanced and revolutionary opinions of the time, was the object of the most violent persecution by the conservative party in church and state, and suffered egregious mutilations at the hands not only of hostile censors but of timorous printers. So thoroughly was it identified with the philosophic movement of the time that the term *Encyclopédiste* became the recognised designation of all attached to a certain form of philosophy. Appearing at Paris in 28 vols. between 1751 and 1772, it was followed by a supplement in 5 vols. (Amst. 1776-77), and an analytical index in 2 vols. (Paris, 1780). Voltaire's *Questions sur l'Encyclopédie* (1770) formed a kind of critical appendix. La Porte's *Esprit de l'Encyclopédie* (Paris, 1768) gave a résumé of the more important articles, and under the same title Hennequin compiled a similar epitome (Paris, 1822-23). Numerous editions of the whole work, more or less expurgated or recast, were issued outside of France; and many minor encyclopædias, such as Macquer's *Dictionnaire Portatif des Arts et Métiers* (1766), Barrow's *New and Universal Dictionary of Arts and Sciences* (1 vol. fol. 1733), and Croker, Williams, and Clek's *Complete Dictionary of Arts and Sciences* (3 vols. fol. 1766), were to a considerable extent quarried out of their massive predecessor, or moulded according to the method expounded by D'Alembert in his preliminary dissertation. In 1780 a privilege was obtained by C. J. Panckoucke for the publication of an *Encyclopédie Méthodique, ou par Ordre des Matières*, which was at first intended to be little more than a rearrangement and supplementing of the matter of Diderot's work; each main subject having a separate 'dictionary' for itself. But its method was too much for it; the scheme, though 166 vols. had been issued by 1832, was never completely realised.

Between 1768 and 1771 there appeared at Edinburgh in 3 vols. 4to the first edition of the *Encyclopædia Britannica*, which was from the beginning a kind of compromise between the alphabetical and the scientific distribution of subjects. Colin Macfarquhar, Andrew Bell, and William Smellie share the credit of the plan. Biographical and historical articles were first introduced in the 2d edition (10 vols. 4to, 1776-1784). The third edition (18 vols.) was completed in 1797; the fourth (20 vols.) in 1810; the fifth, a mere reprint, in 1817. To the sixth edition (1823) Constable, the publisher, prefixed the well-known volume of preliminary dissertations by Dugald Stewart, Playfair, &c. The seventh edition, edited by Macvey Napier, was published by Messrs Black between 1830 and 1842. The eighth (21 vols. and index) appeared 1853-61, under the editorship of Dr Thomas Stewart Traill; and the ninth, edited by Professors Thomas S. Baynes and W. Robertson Smith, was completed in 24 vols. in 1875-88 (Index, 1889). This last

edition was 'pirated' in America by the firm which added a supplementary *Encyclopedia Americana* (4 vols. 1883-89). The ninth edition was reissued in 1898 by *The Times*, exactly as it stood when first printed; and with nine supplementary volumes, new index volume, and maps (1902-3), claimed to be a tenth. The eleventh in 29 volumes was published by the Cambridge Press in 1910-11. With three new volumes (1922) it made the twelfth.

Many notable encyclopædias had meanwhile been appearing—the *Edinburgh Encyclopedia* (18 vols. 1810-30), edited by Sir David Brewster; Wilkes's *Encyclopædia Londinensis* (24 vols. 4to, 1810-29); *Encyclopædia Perthensis* (23 vols. 1816); the *Encyclopædia Metropolitana* (30 vols. 1818-45), arranged, according to a philosophic plan by Coleridge, in four divisions: (1) pure sciences, (2) mixed and applied sciences, (3) biography and history, and (4) miscellaneous and lexicographic articles; the *Penny Cyclopædia*, edited by Charles Knight for the Society for the Diffusion of Useful Knowledge (29 vols., 2 supplemental, 1833-46); and the *English Cyclopædia* (22 vols. 1853-61; a synoptical index, 1862; four supp. vols. 1869-73), founded on the copyright of the *Penny Cyclopædia*, but rearranged into four divisions—viz. geography, natural history, biography, and arts and sciences. In spite of the value of much of its material, this last encyclopædia, like Panckoucke's vast enterprise and Coleridge's ingenious scheme, furnished another proof that no encyclopædia can well be thoroughly popular which is not executed on the plan of a single alphabet. It is partly their rigid adherence to this method that has given their success to the popular German encyclopædias.

The encyclopædia now known as Brockhaus's *Konversations-Lexikon*, which was started by Lobel at Leipzig in 1796, and passed into the hands of F. A. Brockhaus in 1808, gave a great impetus to the production of similar works. It is still one of the most popular of German encyclopædias (new ed. 17 vols. 1908-10). Its principal rivals are Pierer's, and Meyer's *Konversations-Lexikon*. The former (1822-36, 26 vols., with 14 supplemental vols. 1840-56) reappeared in 12 vols. in 1888-93; while the latter has become in completeness and compression the best work of its kind (1st ed. 15 vols. 1857-60, with yearly supplements; 7th ed. 12 vols. 1924 *et seq.*). In all a free use is made of maps, tabular conspectuses, woodcuts, and lithographic illustrations. The Brockhaus *Lexikon* became the basis or model of encyclopædias in most of the civilised languages of Europe—Spanish, Italian, Danish, Swedish, &c.—amongst those in English *Encyclopædia Americana* (14 vols. 1829-46); *New American Cyclopædia* (16 vols. 1858-64), edited by Ripley and Dana (new ed. 16 vols. 1873-76); and *Chambers's Encyclopædia* (10 vols. Edin. 1860-63, edited by Dr Andrew Findlater; new ed. recast and rewritten, 10 vols., edited by Dr David Patrick, 1888-92, and revised from time to time; new ed. 1922 *et seq.*). Others are the *Harmsworth Encyclopædia* (8 vols. 1905), prepared by Messrs Nelson, and reissued as Nelson's in America (12 vols.) and in Britain (25 vols. 1911-12); Johnson's *Illustrated Universal Cyclopædia* (4 vols. N.Y. 1874-78; new ed. 8 vols. 1890-95); the (American) *International Encyclopedia* (1884; partly based on Chambers's; new ed. 1922); the *Globe Cyclopædia* (1879); the *National Encyclopedia*; Blackie's *Modern Cyclopædia*.

Notable modern French works are Pierre Larousse's *Grand Dictionnaire du XIX^e siècle* (15 vols. 4to, 1866-76, with three supplements); *Le Nouveau Larousse* (7 vols. 1901-4); and Berthelot and Dreyfus, *La Grande Encyclopédie* (31 vols. 4to, 1886-1903).

Among all European encyclopædias (and a few only have been mentioned; for every leading lan-

guage could furnish a list) one stands out as a unique example of protracted production. A defect inherent in the constitution of every large encyclopædia brought out in successive volumes is that, as regards literature and the progressive sciences, the earlier portions are passing out of date before the later portions have come into existence. This characteristic is almost caricatured in the famous *Allgemeine Encyclopædie der Wissenschaften und Künste*, which was originally undertaken by Professors Ersch and Gruber in 1818, continued slowly to appear in three several sections of the alphabet, and remains incomplete. There have appeared some 170 parts, many of them containing the most elaborate monographs on individual subjects to be found in literature. An encyclopædia of the sciences to extend to perhaps 1000 volumes, in 40 sections, systematic, not alphabetic, was begun in 1910 under the editorship of Professor Toulouse. A copy of the great Chinese cyclopædia in 5020 Chinese volumes (6109 general headings), printed at Peking in 1726 by command of the Emperor Kang-Hi, reached the British Museum in 1878. *The Great Standard of Yung Lo*, an encyclopædia begun in 1408, and extending to 11,100 vols. (each 1½ inches thick), perished, with the library that contained it, in the attack on the legations at Peking in 1900, the only other copy having been destroyed by fire in Nanking in 1644. A few volumes survive.

An attempt to remedy the defect of protracted production has frequently led to the issue of supplemental volumes, planned so as to bring up the earlier articles to the same time-level as the later articles (notably Brockhaus's, Meyer's, and Appleton's *American Cyclopædia*).

In contrast with the larger encyclopædias may be mentioned the modern attempts to boil down the circles of the sciences into portable form, as in the abridgments (in 1 to 3 vols.) of Brockhaus and Meyer. Similar productions are Beeton's *Dictionaries* and several 'Young Folk's' Encyclopædias, English or American.

The modified term 'cyclopædia' is sometimes used in the same sense as encyclopædia, and sometimes restricted to a work dealing with one subject—for which encyclopædia is now also in use. Thus the *Encyclopædia Biblica* (4 vols. 1899-1903) deals with Biblical and theological subjects, as the Hanck-Herzog *Realencyklopädie* (22 vols. 1906-9) does with theology. There are also a great *Catholic Encyclopædia* (15 vols. and supplement, 1907-22) and a *Jewish Encyclopædia* (12 vols. 1900-7), encyclopædias of law, medicine, &c. *The Teacher's Encyclopædia* (1911) deals with educational matters, and there is an *Encyclopædia of Religion and Ethics* (1908 *et seq.*), edited by Dr Hastings. But many such works—e.g. Hastings's *Dictionary of the Bible* (5 vols. 1898-1904), a *Dictionary of Political Economy* (3 vols. 1894-98; new ed. 1923 *et seq.*), edited by Sir R. H. I. Palgrave, and Grove's *Dictionary of Music* (4 vols. 1878-90; re-edited in 5 vols. by J. A. Fuller-Maitland, 1904-10)—even when equally comprehensive in scope, are content with the less lofty title.

Encyclopédistes, a group of French *philosophes* of the 18th century, leaders in the enlightenment, believers in reason, with deistic or materialistic tendencies, enemies of ecclesiastical absolutism, so called from their connection with the *Encyclopédie* (see ENCYCLOPÆDIA) of Diderot (q.v.) and D'Alembert (q.v.). See also BUFFON, GRIMM (F. M.), HOLBACH, ROUSSEAU (J. J.), and Morley's *Diderot and the Encyclopédistes*.

Encystment, in biology, is the formation of a resistant sheath on passing into a resting stage. See CELL, and for examples AMEBÆ, GREGARINIDA.

Endecott, JOHN, colonial governor of Massachusetts, was born at Dorchester, England, in

1539, and landed as manager of the plantation of Naumkeag (Salem) in 1628. Giving place in 1630 to John Winthrop, he headed a sanguinary expedition against the Indians in 1636, was deputy-governor in 1641-44, 1650, and 1654, and governor in 1644, 1649, 1650-53, and 1655-65. Endecott was an austere Puritan, choleric, benevolent, and brave. He died at Boston, 15th March 1665.

Endemic (from Greek *en*, 'among,' and *dēmos*, 'people'), a term applied to diseases which affect numbers of persons simultaneously, in such a manner as to show a distinct connection with certain localities. Endemic diseases are usually spoken of as contrasted with Epidemic (q.v.) and Sporadic (q.v.). The term endemic indicates that the disease affects habitually, in greater or less numbers, the population within certain geographical limits; while a disease is called epidemic when at times it breaks out and spreads without reference to locality; and, on the other hand, it is regarded as sporadic if it occurs in isolated cases only. Many diseases which are capable of transmission from one human being or one animal to another are at times epidemic, for longer intervals endemic, and at times are kept in existence only by the occurrence of occasional or sporadic cases. For example, cholera and plague, which at times have swept across Europe in devastating epidemics, are constantly endemic in certain cities of India. Small-pox, which at the present day is endemic in many parts of China, has, in the past, at frequent times broken out in serious epidemics. The disease known as cerebro-spinal meningitis is at times epidemic among troops or in certain districts, and again for long periods occurs only at rare intervals in scattered sporadic form.

The causes which make a disease cling to certain localities in endemic form, or which effect its change from endemic to epidemic character, are various. Not all endemic diseases are transmissible from person to person. Some peculiarity of the soil or water or the amount of sunshine may render a disease common among a certain people or in a given valley, while others a little way off are immune.

Goitre is one of the most marked examples of endemic disease occurring here and there all over the world, usually in deep valleys and on elevated plains—e.g. in Derbyshire, in Switzerland, and in the Himalayas—while localities not far removed from these are free. The cause has been assigned to the drinking of water rich in magnesia and lime, but this theory will not explain the fact that similar water is constantly drunk in many districts free from the disease. Devonshire colic is an old example of endemic disease brought on by mineral poisoning in certain districts, in this case due to lead occurring as an impurity in cider. Similar endemic diseases due to the habits of life followed in certain areas are found in the lead-poisoning of the Staffordshire earthenware workers and the 'grinder's phthisis' of the Sheffield cutlers.

In other cases the endemic character of the malady is determined by the presence of some insect which conveys the material of the poison. Malaria, yellow-fever, and sleeping sickness belong to this latter group of endemic diseases, and in these instances the occurrence of the disease is sharply limited to certain woods, swamps, river valleys, or tracts of country infested by the particular species of insect. In the case of malaria the poison causing the disease is of a protozoan nature, and is carried by the *Anopheles* mosquito, in the body of which it undergoes development. Yellow-fever, due to a poison of undetermined nature, has been proved to be transmitted from sick to healthy by the *Stegomyia* mosquito. Both of these diseases are eradicable or controllable by

measures directed against the mosquito, such as drainage of swamps, removal of decaying vegetation, and the like. It is by these means that the Panamá Canal Zone, formerly the home of these diseases, has been rendered habitable by the white man.

Still other diseases are limited in their distribution because the disease is common to man and some lower animal, such as the house rat in the case of plague; the disease therefore may be limited to particular districts or even quarters of a city where these animals inhabit, and the sudden development of an epidemic character in the disease may be due to migrations of the affected animals. A similar relationship between man and animals explains the fact that many diseases due to animal parasites are endemic in limited areas.

Leprosy, and in a less degree tuberculosis, are examples of chronic disease of microbic origin which are of greater frequency in some parts of the globe than others. Thus leprosy, while practically unknown in Britain, France, and Germany, is endemic in Norway, Southern Russia, and Turkey, and is still more common in tropical countries of the East. In the case of this disease, the reason why it should be endemic in some places and not in others is still undetermined.

Enderby Land, on the Antarctic Circle, near the middle of the 'Enderby Quadrant' (0° to 90° E. long.), was discovered by John Biscoe in 1831, on a whaling voyage, and named in honour of his employer, Samuel Enderby, an adventurous London merchant, grandfather of Chinese Gordon. His fleet of whalers first rounded the Horn, and actually opened up the Southern Ocean, discovered the Auckland Islands, and carried the first batch of convicts to Botany Bay. Biscoe, from stress of weather and extreme cold, could not approach Enderby Land within 20 or 30 miles, and was thus unable to say whether it was an island or a strip of continental coast.

Endicott, JOHN. See ENDECOTT.

Endive (*Cichorium Endivia*), an annual or biennial plant, of the same genus with Chicory (q.v.), has been in cultivation since classic times as a garden vegetable, its blanched leaves being much used as a salad. The green-curled variety is the staple one, the white-curled is good for summer and autumn, and the broad-leaved is used for stews and soups. In Britain the seed is usually sown from the middle of May to the end of June, and by a little care and protection plants may be kept fit for use throughout most of the winter.

Endlicher, STEPHEN LADISLAS, a systematic botanist, was born at Pressburg, 24th June 1804. He was destined for the priesthood, but in 1827 commenced botanical and linguistic studies, and in 1840 he became professor of botany in Vienna. Much disturbed by the events of 1848, he fell into melancholy, and in 1849 put an end to his own life. His *Genera Plantarum* (1836-40) has had great influence on succeeding botanists.

Endocarditis, disease of the internal surface of the heart, resulting in the deposit of fibrin upon the valves. See HEART (DISEASES OF).

Endocarp. See FRUIT.

Endocrine Glands, or DUCTLESS GLANDS, are organs of internal secretion. See GLANDS, HORMONES, and articles on the various glands.

Endoderm. See EMBRYOLOGY.

Engagamy. See MARRIAGE.

Engelen, Lindley's disused name for Monocotyledons (q.v.). See also DICOTYLEDONS, BARK, DRAGON-TREE.

Endomorph, a mineral inclosed within another, the latter being a *permorph*. Such inclusions

are very common in the constituent minerals of crystalline schistose and igneous rocks.

Endophagy. See CANNIBALISM.

Endosmose. See OSMOSE.

Endymion, a youth in Greek Mythology, celebrated for his perpetual sleep on Mount Latmos, in Caria. His beauty warmed the cold heart of Selēnē (the moon), who came down to kiss him and lie by his side. Different reasons were given for his sleep, the most general as well as the most poetic being that Selēnē had sent him to sleep that she might kiss him without his knowing. The story inspired the fresh fancy of the young Keats, who shaped it into an imperishable poem.

Enema. See CLYSTER.

Enemy. According to the doctrine of the civil law, as formulated by Ulpian (Digest, 49, 15, 24), those only are enemies 'who have publicly declared war against us or we against them.' In the earlier ages of the Roman republic such a declaration was most solemnly made to the foreign state by the *feciales*, a college of priests who acted as guardians of public faith, and was attended by elaborate religious rites. The various ceremonies accompanying the declaration of war are described by Livy (book i. 24). So now, in order to constitute an enemy, there must exist between duly organised governments a state of war, the commencement of which must be preceded or accompanied by some form of public declaration. The most authoritative statement of the existing law is contained in the rules formulated at The Hague Convention in 1907, which provide that hostilities 'must not commence without a previous and explicit warning in the form of either a declaration of war, giving reasons, or an ultimatum with a conditional declaration of war;' and that 'the existence of a state of war must be notified to the neutral powers without delay, and shall not be held to affect them until after the receipt of a verification, which may, however, be given by telegraph.' In the Great War these rules of The Hague Convention were observed by the belligerents, although hostile acts are alleged to have been committed by both French and German troops before war was formally declared. These rules do not exclude a surprise attack, for they do not prescribe that any period of time shall elapse between the notification and the commencement of hostilities. Where a conditional declaration of war is made by presenting an ultimatum to be accepted within a given time, a state of war commences on the expiry of the time mentioned, if the demands of the ultimatum are not accepted.

The commencement of war immediately affects the position of the citizens of the belligerent states. The principle is that the subjects of an enemy state are themselves enemies. The right to recover debts from, and the liability to be sued by, enemy subjects are suspended during the war. Commercial intercourse with the inhabitants of the enemy country is prohibited, and, under the law of Great Britain, such intercourse, except with the license of the crown, is illegal. In ancient times the property of alien enemies residing within the hostile state might be confiscated, and their persons could be seized. But the usage of nations for a long period has modified this stern rule of the ancient law. It is provided in Magna Charta that, upon the breaking out of war, foreign merchants found in England, and belonging to the country of the enemy, should be 'attached without harm of body or goods' until it should be known how English merchants were being treated in the country of the enemy; 'and if our merchants,' says the charter, 'be well intreated, then theirs shall be like.' The statute of staples, 27 Edw. III.

chap. 17, made a still more liberal and precise enactment in favour of such foreign merchants residing in England. Forty days were allowed them, after the proclamation of war, to remove from the kingdom themselves and their goods, and if by reason of accident that time were not enough, forty days more were to be conceded to them. Modern usage allows to alien enemies, who are not combatants, either active or reservists, in the enemy forces, a reasonable time to withdraw from the territory of the hostile state on the outbreak of war. Enemy subjects who are permitted or compelled to remain in the territory of the belligerent state may have restrictions put upon their freedom. Thus by the Aliens Restriction Act, 1914, and the Orders in Council made under that act, many restrictions were imposed during the recent war on enemy subjects resident in this country. These restrictions took various forms, such as internment, registration and surveillance, removal from specified districts, and prohibitions against the possession of certain articles, ranging from firearms to pigeons and cipher codes. The old practice of confiscating on land the property of enemy subjects, whether resident in the territory or not, is obsolete.

In determining 'enemy' character there are two tests, the national and the territorial. When the question is as to a man's personal rights—e.g. whether he is liable to be interned, or whether he may live in a prohibited area—the main test is nationality. On the other hand, when the question is as to his rights as a party to a contract or as a litigant, the main test is territorial, that is to say, the place in which he resides, or carries on business. If he is voluntarily resident, or carries on business, in enemy territory, he is an alien enemy for purposes of trade and litigation, whatever his nationality may be. The question as to the circumstances in which an enemy character is to be attributed to a corporation received much consideration during the recent war. A corporation or company *prima facie* takes its national character from the country in which, and under whose laws, it is incorporated; but the judgment of the House of Lords in *Dunster Co.*, 1916, 2 A.C. 307, established that, if the agents of a company or corporation, or the persons who are *de facto* in control of its affairs, are 'enemies,' the company or corporation is in the position of an enemy. The national status of individual shareholders does not of itself affect the national character of the company; but the enemy status of individual shareholders and their conduct are elements to be considered in determining whether the agents of the company are in fact adhering to, taking instructions from or acting under the control of, enemies.

In modern times certain general rules have been laid down for the purpose of regulating the rights of offence and defence, and setting limits to the violence permissible against enemies. In 1874 an international conference held in Brussels devoted much time to the elaboration of rules for military warfare. The most authoritative statement of the existing rules on this subject is contained in the 'regulations' annexed to The Hague Convention of 1907, which amended the provisions of the Declaration of Brussels and of the Convention of 1899. The laws of war, as there enunciated, prohibit, *inter alia*, the use of poison or poisoned weapons; the killing or wounding of an enemy who has surrendered; the use of arms, projectiles, or substances likely to cause unnecessary suffering; and any destruction or seizure of enemy property not imperatively called for by military necessity. Any compulsion of the population of occupied territory to take part in military operations against their country is forbidden; and

neither requisitions in kind nor services can be demanded from the inhabitants, except for the needs of the army of occupation. The Hague regulations, while recognising military necessity as a legitimate element for consideration, were intended to prevent a belligerent from having recourse at discretion to such a plea. The German Official Instructions on the usages of war on land, however, treated the Hague regulations with scant respect, and set up military necessity as the governing factor in the operations of war. (These Instructions are translated, with a critical introduction, by J. H. Morgan—*sub nom.*, *The German War-Book*.) In the Great War the application of the military usages laid down by Germany in these Official Instructions aroused the indignation of the civilised world.

Experience during the recent war has demonstrated that the international code of rules, which seeks to control, and impose limitations on, the conduct of military operations, is the weakest part of international law. The existence of rules, which are not observed and cannot be enforced, only serves to discredit the law. A renewal of the attempt to establish rules for the control of hostilities cannot be more successful in the future than it has been in the past, unless unity of international action is secured and an effective sanction is found for the enforcement of rules which are formulated by international agreement. The application of science to warfare, the progress of invention, and the increasing efficiency of aircraft, submarines, bombs, poisonous gases, and other instruments of destruction, will inevitably render war in future more intolerable than it has been in the past. The very nature of war is altering; for war tends more and more to become not merely a conflict between opposing armies or navies, but a contest in endurance between the whole organised societies of the belligerent states. It seems certain that, if wars are permitted to continue, the sufferings of the civilian populations from blockade, bombardment, and other military operations will be vastly greater even than those undergone in the late war. The hope of mankind lies not in devising rules for controlling the methods of warfare, but in founding an international order which will prevent the recurrence of war between civilised states. For other information on the rules and usages of war, reference is made to the articles CONTRABAND OF WAR, BLOCKADE, NEUTRALITY, PRIZE, PRISONERS OF WAR, GENEVA.

Energumen. See DEMONOLOGY.

Energy. The term *energy* as applied to a material system is used to denote the power of doing work which is possessed by that system. There is no manifestation of energy apart from matter. In consequence of this, matter is sometimes defined as the vehicle or receptacle of energy. A bullet projected vertically upwards possesses a great amount of energy; it can do work in overcoming obstacles to its motion. But the higher it rises the less resistance can it overcome; and at last, having reached the greatest height it can attain, it seems incapable of doing work. Yet it is not really incapable of doing work. It will gradually acquire speed in the downward direction, and will finally (the resistance of the air being neglected) reach the ground with the same speed as it had at first, and is thus capable of doing the same amount of work. Therefore, when at its highest position and seemingly incapable of doing work, it really possessed energy as at first. Hence we are led to recognise two leading types of energy—energy of *motion* and energy of *position*; or, as they are usually called, *kinetic energy* and *potential energy*. We have many examples in nature of

both types. Currents of air or of water possess kinetic energy; a stone resting on the brow of a cliff, and water at the edge of a fall, possess potential energy.

But although energy may be classed under one or other of these two types, there are many forms in which it is manifested. There is *energy of visible motion* and *energy of position in visible arrangements* of bodies, as in the bullet moving upwards or downwards, or at rest at its highest position. A bent spring evidently possesses potential energy. An oscillating pendulum possesses alternately kinetic energy and potential energy. At the extremity of its swing the energy is entirely potential; at the middle of its range the energy is entirely kinetic; at intermediate positions it is partly of one kind, partly of the other. *Heat* is another form of energy. The particles of a hot body are in rapid motion, and the hotter the body the more rapid is the motion. The motion is on an invisibly small scale, but it can be communicated to other matter in such a way as to produce visible motion. Thus the invisible motions which constitute heat are applied in the steam-engine or air-engine to produce visible motion of a piston, and so to perform mechanical work. When Heat (q.v.) becomes *latent* in a body, part at least of the energy is spent in overcoming molecular forces, and the relative distances of the molecules of the body are altered; and so we have potential energy stored up in the molecules. Again we have the so-called *radiant energy*—energy propagated by means of undulations through the ether. This includes light as well as radiant heat, the two differing merely as regards wave-length. So also it includes the electro-magnetic waves recently experimentally demonstrated by Hertz, the wave-length of which may be many feet, or even miles; instead of $\frac{1}{1000}$ of an inch as in orange-coloured light. Vibrations in the particles of a hot or luminous body are communicated to the ether, and propagated by wave-motion through it at the rate of 186,000 miles per second. In the ether, therefore, the energy is partly potential, partly kinetic (see ETHER). There is also energy of *chemical separation*. Carbon and oxygen combine in the burning of ordinary fuel, and the energy which they contain in their separated state is used to produce mechanical work, as in the steam-engine; and in the explosion of gunpowder visible energy of motion is produced even more directly from the energy of chemical separation of the constituent substances. We have also potential energy of *electrical separation*, for if two conductors be charged with electricity, one positively and the other negatively, an attraction between them becomes apparent. In approaching each other the charged bodies can be made to do work. Again, when we have *electricity in motion* in a conductor, we have another means of producing work. The current of electricity produces heat and also tends to produce motion of other conductors in which electric currents flow. The attraction or repulsion between magnets can also be made to produce work, and so also we can get work from the mutual action between magnetised bodies and conductors in which electric currents flow.

Thus we see that energy may be manifested to us in a number of different forms; but as we do not yet know the ultimate nature of matter or of electricity, we cannot assert that the forms which we have just considered are all essentially distinct. It is not impossible that the energy of chemical separation is due to electrical separation, or that energy resulting from magnetisation is due to motion of electricity.

In the above remarks we have spoken not only of the production of work from energy, but of the

production of one form of energy from another, and of the passage of potential energy into kinetic energy. This change of energy from one form to another is known as the *Transformation of Energy*, and distinguishes it from matter. While matter is passive or inert, energy is continually in process of transformation—indeed we are cognisant of energy only in virtue of its change. We should never know that a moving cannon-ball possessed energy if we did not see its destructive effects; we should never know that electrified clouds possessed energy did we not see damage done by lightning.

Of the transformation of energy a few examples must suffice. We cause carbon and oxygen to combine in the furnace of a steam-boiler, or hydrogen and oxygen to combine in the cylinder of a gas-engine. This produces invisible motion of molecules, which in turn produces visible mechanical motion of the piston and connected mechanism. This motion may be communicated to a 'dynamo,' causing conducting wires to move in a magnetic field. Thus electric currents are produced in the wires. These currents may produce heat in, and cause radiation from, a highly resisting carbon filament. Or they may produce magnetic effects, and finally mechanical motion, in a motor. Thus energy may be applied by means of the dynamo and motor to the production of mechanical work in a place where it would not be easy to use an engine directly.

In the case of the telephone, the condensations and rarefactions of the air (which produce sound when they impinge on the ear) cause vibrations of the telephone diaphragm. As this motion occurs in the near neighbourhood of the pole of a magnet, electric currents of varying intensity and direction are produced in a coil of wire surrounding the pole. These currents pass round the magnet of the receiving telephone, and produce magnetic effects similar to those occurring at the sending instrument. Therefore similar mechanical effects are caused, and so like sounds are heard.

In the voltaic battery energy of chemical separation is transformed into energy of current electricity. The electric current may be passed through slightly acidulated water. The water is thus broken up into its constituents, so that energy of chemical separation is again obtained.

Many other examples of the transformation of energy might be given, but it is sufficient to remark that any form can be directly or indirectly transformed into any other form. A matter of greatest importance to us is the determination of the sources or source from which ultimately we derive mechanical work. The work obtained from animal labour is derived from the chemical energy of the food supplied to the animal. This food is vegetable food either actually or ultimately; for, even if it be actually animal, the energy of such food is ultimately traceable to the vegetable world. Now all vegetables grow by means of solar radiation, which decomposes carbonic acid in their tissues, so that energy obtained from animal labour is obtained actually from the sun. And if we use fuel in an engine, the energy of the fuel is in the same way due to the sun. If we use wind-power to drive our machines, the energy is also solar, for it is the sun which causes the atmospheric currents. So also the work obtainable from moving water, except in the case of tidal currents, is due to the heat radiated from the sun. Thus the sun is the great source of our energy; and, if he ceased to supply us with it, we could no longer produce work, except indeed in so far as he has already supplied us with a store in potential forms.

We have already stated that the energy of a material system is sometimes exhibited in one form, sometimes in another, but this statement

may be greatly extended. If no energy leaves the system, and if no new energy enters it, the quantity which disappears from one form reappears entirely in another. This is known as the principle of the *Conservation of Energy*. In the case of the bullet projected upwards, the potential energy in the highest position would be the exact equivalent of the original kinetic energy, if none were communicated to the air or other bodies. The same would hold in the case of the pendulum, if no energy were given from the system to the air or the supporting arrangement. [At one time the expression conservation of *force* was used instead of conservation of *energy*, but the word '*force*' meant then what we now call '*energy*.' The conservation of *force*, as we now use the word, means something totally different. See *FORCE*.]

The law of conservation of energy may be stated as follows: The total amount of energy in a material system cannot be varied, provided the system neither parts with energy to other bodies nor receives it from them. This law is merely a generalisation from observed facts; a single known exception would cause us to abandon or modify the statement. But the amount of positive proof in favour of the law is now exceedingly great, perhaps the strongest proof being afforded by the accuracy of scientific predictions founded upon the assumption of its truth. As an example, we may refer to the prediction of the lowering of the freezing-point of water by pressure. The assertion of the principle of conservation of energy is equivalent to a denial of the possibility of the '*Perpetual Motion*' (q.v.).

In a scholium to his third law of motion, Newton asserts that 'if the action of an external agent is estimated by the product of its force into its velocity, and the reaction of the resistance in the same way by the product of the velocity of each part of the system into the resisting force, arising from friction, cohesion, weight, and acceleration, the action and reaction will be equal to each other, whatever be the nature and motion of the system.' Now the product of a force into the velocity produced by it is simply the rate at which the force does work. Hence, as was first pointed out by Thomson and Tait in their work on *Natural Philosophy*, this statement of Newton's is almost a complete statement of the principle of conservation of energy. Newton did not know what becomes of work spent in overcoming friction; he believed that it disappeared from the system. Had he known that it was converted into an exact equivalent in the form of heat, his statement would have been complete. It was not until long after Newton's time that Heat (q.v.) was recognised to be a form of energy. The experiments of Rumford and Davy first led to this result. Rumford's experiments were made in 1798 and 1799, on the work done, and the heat produced, in the boring of cannon. He concluded that heat must be due to motion. Davy's experiments on the melting of ice by friction were also made about the same time, but it was not until 1812 that he came to the conclusion that 'the immediate cause of the phenomenon of heat is motion, and the laws of its communication are precisely the same as the laws of the communication of motion.' From data given by Rumford, it may be calculated that 940 foot-pounds of work are necessary to produce heat sufficient to raise the temperature of one pound of water by 1° F.—the foot-pound being the work done in raising a pound through one foot against gravity. The researches of Colding and Joule, however, have given a far better determination of the mechanical equivalent of heat; and Joule's experiments, especially, extend to many forms of energy, and prove their exact

equivalence. His experiments on the heating of water by friction gave results varying from 770 to 774 foot-pounds as the *mechanical equivalent* of heat. His final result was 772, the possible error being much less than 1 per cent. Many indirect methods have also been used by Joule and others. Thus, the mechanical equivalent may be directly determined by observing the quantity of heat developed during the passage of an electric current of known intensity through a conducting wire of known resistance. The result for heat being assumed, it is easy to find the work-equivalent of other forms of energy. Thus, we can determine the equivalent in work of the energy of chemical separation—e.g. by dissolving zinc in sulphuric acid, and observing the heat developed. If the zinc be dissolved in a voltaic cell which is producing a current, heat is evolved in the various parts of the circuit in proportion to their resistance. Thus, by placing in the circuit a wire of great resistance, almost all the heat will be developed in the wire, and so may readily be measured. Again, by making the current produce work through the agency of an electro-magnetic engine, the work may be directly measured, care being had to take account of energy lost in the process by friction or otherwise. Less heat is developed in the circuit in proportion as the work done is greater, the total energy being constant. So, by expending work in driving a magneto-electric machine, we may find the work-equivalent of electric energy. As the electric energy ultimately becomes heat, Joule used this method in one of his determinations of the quantity of heat produced from a known amount of work.

We have seen that we can neither increase nor diminish the total quantity of energy in the universe, while any one form of it may be changed into any other; but we have made no inquiry as to whether or not all forms are equally transformable. The question is obviously of vital importance to us; for, if one form be less transformable than the rest, when we change any other kind into this one, we shall not be able completely to re-transform it. Thus there will be a tendency for all forms to be reduced to this more permanent form, and we shall not be able so readily to obtain mechanical work from it. Lord Kelvin first pointed out that there is in nature a universal tendency to this *Dissipation* (or, as it has since, and perhaps preferably, been called *Degradation*) of Energy. The final form which all energy tends to take is that of heat. But heat tends continually to diffuse so as to equalise temperature; and, when there is no difference of temperature between the source and condenser of a heat engine, no work can be obtained from it, for the amount of work which can be obtained from a given quantity, H , of heat (see THERMO-

DYNAMICS) is $JH \frac{T - T_0}{T}$, T and T_0 being the absolute temperatures of the source and condenser respectively, while J is the mechanical equivalent of heat. Obviously $JH \frac{T_0}{T}$ is the quantity of energy

lost for useful purposes so far as this engine is concerned. This shows that all the amount of heat supplied cannot be transformed into work, unless the condenser be at the absolute zero of temperature. If we take as our source of heat in one case a cubic foot of some metal at a given absolute temperature, and in another case two cubic feet of the same metal containing together the same quantity of heat as the one cubic foot formerly contained, and therefore at half the temperature provided the specific heat be constant, it is obvious, from the above expression, that twice as much heat will be lost in the second case as in the first. Hence, we see that heat at low temperature is much less use-

ful than the same quantity of heat at high temperature. And a corresponding statement is true for other forms of energy. Thus, if we have two Leyden jars alike in every respect, and charge one with a certain quantity of electricity, we can get a certain amount of work from the arrangement, which is made evident by the loudness of the sound and the brightness of the flash on discharge. But if we first divide the original charge between the two jars, and then discharge them, we can only get half the amount of energy. The reason is that the potential is only one-half of what it was in the first case; and the higher the potential of a given quantity of electricity is, the greater is the amount of work it can do, just as the usefulness of heat depends upon temperature. In fact, if V be the potential of the charge E in the first case, $\frac{1}{2}VE$ is the energy; but in the second case the charge of each jar is $\frac{1}{2}E$, and the potential of each is $\frac{1}{2}V$, so that the energy in each is $\frac{1}{4}VE$, the total amount being therefore $\frac{1}{2}VE$, or only half of the original energy. The remaining half is accounted for by the energy spent in dividing the charge—light, sound, and heat being produced. Again, work may be obtained by letting compressed gas expand; and the amount of work depends upon the pressure. The gas may be allowed to expand without doing work, but energy will be dissipated, for the expanded gas, being at less pressure, cannot do so much work as it could do before expansion.

Examples of the degradation of energy are everywhere seen in nature. The fact that the optical image of a body is less distinct than the object itself is due to the fact that some of the so-called radiant energy is absorbed by the reflector, and takes the form of heat. The vibrations of a tuning-fork die down because the energy is communicated to the surrounding air, but they also diminish because of the production of heat from internal friction in the vibrating body. The stilling of storms is accompanied by dissipation of energy. Possibly starlight is weakened in its passage through the ether. Indeed, no instance of transformation of energy can be pointed out in which there is not also dissipation of energy.

As we have already remarked, since all forms of energy tend to take the form of heat, and since heat is constantly tending by conduction and otherwise to equality of temperature, it follows that, unless the universe be infinite, energy will ultimately become useless for the production of work. The total amount of energy will, in accordance with the principle of conservation, be the same as at first, but any transformation of it will be impossible. There are two ways in which we may regard the energy of a given system; we may regard it from without the system, or from within. When we speak of the total energy of a system, we regard it from the outside. Thus, if we consider a thermal system, the total energy is the work which could be done by the heat in passing from the system to its surroundings, these being supposed to be constantly at the absolute zero of temperature. But the available energy (called in this case the *thermo-dynamic motivity*) is usually regarded as the greatest amount of work which can be obtained by equalising the temperatures of its various parts amongst themselves. [The motivity might, of course, also be regarded from without. In this case it would be the quantity of work obtainable by reducing all the parts of the system to some definite temperature.] The available energy of the universe, supposed finite, will therefore ultimately be zero. The energy of relative motion of its parts tends, in virtue of friction, to take the form of heat. Though we have no direct confirmation of the statement, yet we may conclude from analogy that the relative

motion of the planets and of all heavenly bodies tends to cease. Thus, ultimately, potential energy of gravitating matter must become kinetic energy of visible motion, and then heat; so that the universe will at last contain only one huge material body rotating about its centre of inertia, and the rotation too must cease in time. And even the molecular motions must largely cease, being communicated to the ether. All this is, of course, pure speculation. We might even, if we considered it profitable, speculate further with Rankine and others as to the possibility of the restoration of the availability of energy. If the universe be finite we may have reflection of radiant energy from its boundaries. A material body coming into a focus might be instantly vaporised, the radiant energy becoming again high-temperature heat.

The second law of Thermodynamics (q.v.) is essentially a statement, for the case of heat and mechanical work, of the principle of the dissipation of energy. Its proof, as given by Lord Kelvin, depends upon the assumption that we cannot produce work from heat which is entirely derived from the colder of two bodies used as the source and condenser of a heat-engine. On an excessively small scale heat does pass in nature from a cold part of a body to a hot part, so as to increase the difference of temperature. In an excessively small portion of a gas, the quicker moving particles may be found in one part and the slower moving particles in another, even although the motion was uniform at first. Similarly, by moving in portions of the sides of a vessel containing gas when no particles were impinging upon them, we could increase the motivity of the system without doing work. As this is practically impossible, we see that the truth of the second law of thermo-dynamics depends essentially upon the extreme smallness and the great number of the particles of a body; so that, in the case of the gas, the motivity is increased only because work is done in compressing the gas which takes the form of heat, and is then removed from the system. Thus, while there is increase of motivity of the energy of the system, there is degradation of external energy.

If at any instant the motion of every particle of matter in the physical universe were reversed, the dissipation of energy would cease. Available energy would increase, for everything would occur over again exactly as in past time, but in the reverse order. This increase of availability would, however, only last until the configuration which existed at the commencement of the present order of things was reached, when dissipation of energy would again occur. This reversal of motion might occur in a system containing a very few particles, but we must regard it as an impossibility in the physical universe as a whole.

See the articles in the present work on THERMODYNAMICS, HEAT, LIGHT, ELECTRICITY, RADIUM, FUEL, &c. On the subject of the preceding article, see TAIT'S *Recent Advances in Physical Science* (1876) and *Thermodynamics* (1877); Balfour Stewart's *Conservation of Energy* (1880); Clerk Maxwell's *Heat* (1875); and recent works on Radio-activity.

Enfantin, BARTHÉLEMY PROSPER, one of the chief representatives of the Saint-Simon school of Socialism, was the son of a banker in Paris, where he was born 8th February 1796. He went to the École Polytechnique in 1812, but having joined the pupils who left school and fought against the allies on the heights of Montmartre and St Chaumont, he was expelled in 1814. Enfantin saw Saint-Simon only once, and apparently joined the school about the time of the death of the master in 1826. After the July revolution of 1830 Enfantin associated himself with Bazard for the active propagation of Saint-Simonism. Bazard expounded it in its relations

to philosophy and politics; Enfantin mainly in its relations to the social state. Soon, however, a schism broke out between the two on the question of marriage and the relation of the sexes. Enfantin recognised two sorts of marriage, one permanent, to suit steady and constant temperaments, the other changing and temporary, to suit the lively and mobile. A theory so subversive of social order led to the intervention of the government. The 'Supreme Father' (as his disciples were wont profanely to call him) was, in 1832, sentenced to two years' imprisonment and to a fine of 100 francs. Being released at the expiration of a few months, Enfantin went to Egypt for a time. He was subsequently appointed a member of the Scientific Commission for Algiers, and on his return from Africa wrote a sensible, interesting book, entitled *Colonisation de l'Algérie* (Paris, 1843). After the revolution of 1848 he edited the journal entitled *Le Crédit Public*. He afterwards held an important situation on the Lyons and Mediterranean Railway. He died August 31, 1864. That Enfantin was endowed with very extraordinary powers of fascinating and managing men is shown by the influence he exercised over a numerous body of clever and enthusiastic disciples. His plans for the construction of the Suez Canal paved the way for the great project later realised by Lesseps. The principal works of Enfantin are his *Doctrines de Saint-Simon*, in conjunction with others (1830); his *Traité d'Economie Politique* (1831); *La Religion Saint-Simonienne* (1831). An edition of the collected works of Saint-Simon and Enfantin (Paris, 1865 *et seq.*) extended to 40 volumes (17 of them Enfantin's).

Enfeoffment. See FEOFFMENT.

Enfield, an urban district of Middlesex, 12 miles by rail N. of London, with a population of over 60,000, is the seat of a government small-arms factory. See RIFLES. Charles and Mary Lamb lived for a time in Enfield before removing to Edmonton.

Engadine, a famous valley in the Swiss canton of the Grisons, and one of the loftiest inhabited regions in Europe, extends north-east for about 65 miles along the banks of the Inn and its lakes, from the foot of Mount Maloja to the village of Martinsbruck. It is divided into two portions—that toward the south-west, called the Upper Engadine, and that toward the north-east, the Lower Engadine. The latter is the more wild and bleak; but the Upper Engadine, although it is more open, and possesses fine meadow-lands, has also an inclement climate throughout, except in the extreme south-west. In the Lower Engadine, abutting on Italy, a Swiss national park for the complete preservation of natural life was established in 1919. The Inn has many villages upon its banks, the highest of which, St Moritz, is 6090 feet above sea-level, while the lowest, Martinsbruck, is 3343 feet. Most of these villages have of late years become, as health and pleasure resorts, clusters of inns. The influx of many strangers has altered many of the old habits of the people; but, though no longer the nearly invariable rule, it is still not uncommon for the young men to betake themselves to the large towns of the Continent, whence they return, with the little fortune gained as confectioners or waiters, to end their days in their cold, lovely valley. The people are almost all of the Reformed or Calvinistic Church. The language most generally spoken is Ladin, a Romance tongue, differing from the other Romance dialects of the Rhetian Alps, and bearing a resemblance to Italian.

Engagement, THE, between Charles and the Presbyterians. See NEWPORT.

Engelhardt, JOHANN GEORG VEIT (1791-1855), professor of Theology at Erlangen, wrote a church history (1834) and a history of dogma (1839).

Engels, FRIEDRICH, socialist, was born 28th November 1820, the son of a Barmen manufacturer, and while conducting a branch of his father's business at Manchester wrote his work on the condition of *The Working Classes in England* (1844; new ed. 1892; trans. N.Y. 1887). He is best known as the friend, colleague, and continuator of Marx (q.v.; and see SOCIALISM), and author of works on the family (1884); Feuerbach's philosophy (1888); and on the development of Socialism (4th ed. 1891). In 1850-69 again at Manchester, he subsequently lived mainly at London, and died 5th August 1895. See *Life* by Bernstein (1896).

Enghien, (1) a summer resort of the Parisians, 7 miles N. of Paris, on a small lake, with five sulphur-springs; pop. 6000.—(2) A manufacturing town in the Belgian province of Hainault; pop. 5000.

Enghien, LOUIS ANTOINE HENRI DE BOURBON, DUC D', only son of the Duc de Bourbon, was born at Chantilly, 2d August 1772. In 1792 he entered the corps of *émigrés* assembled by his grandfather, the Prince of Condé, on the Rhine, and commanded the vanguard from 1796 until 1799. At the peace of Lunéville, in 1801, he went to reside at Ettenheim in Baden. When the Bourbon conspiracy, headed by Cadoudal, Pichegru, &c., against the life and authority of Bonaparte, was discovered at Paris, the latter chose to believe that the Duc d'Enghien was privy to it, and unscrupulously resolved to seize the person of the duke. On the night of the 14-15th March 1804 the neutral territory of Baden was violated, and the duke, with two attendants, was captured, and carried prisoner to Strasburg, and thence to Paris and Vincennes. On the early morning of 20th March he was tried before a military commission, consisting of eight officers, and after a five hours' examination was condemned to death. Half-an-hour later, between four and five, he was shot in the castle moat, and buried in the grave already dug for him. So cruel and audaciously criminal an act has fixed a deep stigma on the character of Bonaparte. M. Dupin published the records of the trial, and showed the illegality of the proceedings of the military commission. This illegality was publicly acknowledged by General Hullin, the president of the court. Thiers as far as possible exculpates Bonaparte, while Lanfrey adopts the most adverse verdict, and Welschinger lays much of the guilt on Talleyrand. Fouché said that it was worse than a crime—it was a blunder. See *Le Duc d'Enghien*, by Welschinger (1888; new ed. 1913); his *Correspondence* (1904-10); and *The Cambridge Modern History* (vol. ix. 1906).

Engine. See DYNAMO-ELECTRIC MACHINES, INTERNAL-COMBUSTION ENGINE, STEAM-ENGINE, STEAM TURBINE, &c.

Engineering, the business of the engineer, is the art of designing and superintending the execution of works of a constructive character, such as roads, railways, bridges, canals, harbours, docks, works for supplying water to towns, drainage and sewerage works, as also the working of metals and the making of machinery.

The duties of the military engineer are defined in the next article. The civil engineering profession is subdivided into several sections. The railway engineer projects and superintends the execution of railways and all the works in connection with them, such as the alteration of roads and streams, the construction of viaducts, bridges, cuttings, and embankments. The hydraulic engineer plans and superintends the works connected with the supply of water to towns, irriga-

tion, drainage, the protection of low lands from inundation, and the use of water as a motive-power. The dock and harbour engineer has the management of all works connected with the sea or navigable waters, such as the construction of piers, breakwaters, docks, harbours, and lighthouses.

The mechanical engineer is principally concerned in the manufacture of machinery, the working of metals, the construction of ships, steamers, cannon, and all the various structures in which the metals bear a prominent part. The marine engineer makes parts of ships, and the machinery in ships and boats; or he takes charge of an engine on board ship. Then there are mining engineers, who discover minerals and manage mines; sanitary engineers, who are specially engaged in the drainage of towns; and electric engineers and many other less prominent divisions of the profession. Any one who tends an engine is also called an engineer. In many engineering works the *contractor* takes a very important part; he executes the works from the designs, and under the direction and superintendence of the civil engineer, and on his ability and good management the success of undertakings very materially depends.

Among the most notable of the engineering works belonging to very remote antiquity are the pyramids of Egypt. The rude stone monuments of the north, as at Stonehenge and Carnac, also testify to some engineering skill. The harbours and temples of ancient Greece are very memorable. The buildings of ancient Rome—its theatres, temples, baths, and aqueducts, its roads, bridges, and drainage-works, vie in extent and magnificence with the most celebrated works of modern days. From classical times down to the commencement of the 18th century the most extensive works executed were the canals, embankments, and other hydraulic constructions used by the Dutch for the purposes of inland navigation, and to protect their low lands from the sea; the canals of North Italy; and the cathedrals and fortifications of medieval Europe.

Civil engineering, as a distinct *profession*, may be said to have originated, in England, about the middle of the 18th century; since that time the improvements in the steam-engine by James Watt, its subsequent application to the railway-system by George Stephenson, and its use in navigation have given a great impulse to commerce and civilisation. Among celebrated engineers are the Stephensons, Rennies, the Brunels, Telford, Smeaton, Ericsson, Eads, Krupp, Fairbairn, Armstrong, Siemens, Bessemer, Fowler, and Baker.

The education of engineers should embrace a fair knowledge of pure mathematics, and of the mixed sciences of natural philosophy, such as mechanics, hydrostatics, hydraulics, and optics, as also of drawing and arithmetic. The principal society of engineers in Britain is the Institution of Civil Engineers, established in 1818, 'for facilitating the acquirement of professional knowledge, and for promoting mechanical philosophy.' There are now everywhere colleges and schools in which engineering is a special study.

The more important operations in engineering, and the most famous triumphs of the art, are treated of under such heads as AQUEDUCT, BREAKWATER, BRIDGE, CANAL, DOCK, HARBOUR, INTERNAL-COMBUSTION ENGINE, LIGHTHOUSE, MINING, RAILWAYS, ROAD, SHIPBUILDING, STEAM-ENGINE, STRENGTH OF MATERIALS, TRACTION-ENGINES, WATER. For machinery, see also the articles on Printing, Weaving, Spinning, Metallurgy, and the other arts and trades discussed in this work.

Engineers, THE CORPS OF ROYAL, formed in 1763, is an important branch of the British army. A similar organisation exists in all regular armies. The duties devolving upon military engineers

include the design, construction, and maintenance of fortifications. In war, the nature of their duties may be judged from the units into which the corps is divided—5 field troops, 16 field companies (these two, of which the former move with the cavalry, have the very active duties entailed by close relation with the fighting troops, entrenching, bridging, preparing localities for defence, road-making, hutting, demolitions, water-supply, and all operations requiring technical skill), 3 bridging 'trains,' 3 balloon companies, 14 telegraph companies (aerial, cable, and wireless), 1 search-light company, 3 railway companies, 31 fortress, with 9 depot or training companies at Chatham and 1 in India, 2 survey companies. The numbers date from before the Great War, during which there was a vast increase. The field company has a *personnel* of 215, with 73 horses. The men, who are called sappers, are enlisted, for the most part, with a previous knowledge of some handicraft of a kind likely to be useful, and they receive 'engineer' pay in addition to ordinary pay. The duration of colour service and reserve service varies in the different branches, but the two together amount to 12 years.

In India, the rank and file of the 'sappers and miners' are Indians, commanded by British officers, and the units (23 companies) correspond to those at home.

Except those of the coast battalion and the quartermasters, who rise from the ranks, all officers pass through the Royal Military Academy or Royal Canadian Military College (see COMMISSION), and begin their career by a special course at the School of Military Engineering at Chatham, the headquarters of the corps. There are also, for later instruction, the balloon school and the electric-lighting schools at Portsmouth and Plymouth. They receive 'engineer' pay beside their ordinary pay, and often hold, especially in India in the Public Works and other departments, posts which carry large salaries, irrespective of their army rank. Promotion is by length of service, up to the rank of major, and is not dependent on a vacancy.

At the War Office there is an Inspector of Royal Engineers, and officers of the corps are to be found in most departments of army headquarters (see ARMY ADMINISTRATION). An assistant-adjutant-general has charge of 'personal services,' that is, of the officers of the corps. The Ordnance Survey is carried out by the Royal Engineers, the chief office being at Southampton. The special reserve (see ARMY) and the territorial engineers are 'Royal' engineers. The former has 2 siege companies, 3 railway companies, and about 100 unattached officers. The Territorial Force has over 100 companies, comprising all the varieties, details of which can be found in the official Army List (q.v.), and a large number of unattached officers. Australia, New Zealand, and Canada have their companies, &c., of Royal Engineers, and Hong-kong, Singapore, and Ceylon have engineer volunteers. See Major-General Whitworth Porter's *History of the Corps of Royal Engineers* (2 vols. 1889).

Engineers, in the Royal Navy, are the class of officers who attend and manage the machinery on board vessels of war. On the first introduction of steam into the service engineers were obtained from private engineering establishments, or from merchant-steamers, and their exact status was undefined and ambiguous. In 1847 and 1848 their position became more recognised, and the higher grades were raised from the rank of *warrant* officers to that of *commissioned* officers of a civil branch. This introduced a higher class of men into the navy. At the present day the use of steam and electricity for every purpose has so enormously increased in war-

ships that the engineers' position has become one of the first importance, and high emoluments, with enhanced rank, have induced some of the ablest men to serve afloat. Till 1903 the grades were those of chief-inspector of machinery, inspector of machinery, fleet-engineer, staff-engineer, chief-engineer, engineer, and assistant-engineer, ranking with colonel, lieutenant-colonel, major, captain, and lieutenant in the army respectively. All these commissioned officers were strictly examined before admission; their rank and promotion being by selection, and dependent on skill, character, &c. For many years engineer officers had been dissatisfied with their position as non-executives in view of the growing importance of their duties and the largely increased engine-room staff under their orders, over whom they could exercise no executive control. In order to settle the difficulty the Admiralty at the end of 1902 brought out an order altering completely the whole system of entry and training of naval officers, including the engineers. Under this system (as has been said at NAVY) all officers for the executive and engineer branches of the navy enter under identical conditions as naval cadets between the ages of 13 $\frac{1}{2}$ and 13 $\frac{3}{4}$, and are educated and trained together until passing as sub-lieutenants. The next stages of their education are as indicated at NAVY; and when they have been to sea for three years, and been confirmed as sub-lieutenants, they are distributed between executive and engineer branches. As far as possible they are allowed to choose which branch they will join; but at the time of the entry of cadets, parents or guardians must undertake for them that they are prepared to serve in any branch if required. Sub-lieutenants of the engineering branch go through a special course at Keyham, at the end of which they are eligible for promotion to the rank of Lieutenant (E), and may rise to the rank of Rear-admiral (E). During the transition period following on the introduction of the new system the Admiralty granted executive titles to the engineer officers then on the lists, and arranged that they should be known as Engineer-lieutenants, Engineer-commanders, and so on; and, from 1st January 1915, they were classified as part of the military branch of the navy. Under the scheme of pay introduced in 1919 for naval officers, the salaries of engineer officers of old and new styles were made the same.

Engis, a cave beside the Meuse, near Liège. The much-discussed Engis skull, found there by Schmerling in 1833, is now thought to be Neolithic.

England is the southern, the largest, and by far the most populous portion of Great Britain, the largest and most important of European islands. Separated from Belgium, Holland, Germany, and Denmark by the North Sea, from France by another 'streak of silver sea,' the Channel, and from Ireland by the Irish Sea, the kingdom of England has a land frontier of about 120 miles towards Wales and 70 miles towards Scotland. In shape it forms an irregular triangle, of which the eastern side measures in a straight line about 350 miles, the southern 325 miles, the western 425; but its shores are so deeply indented by bays and estuaries as to make the coast-line longer in proportion to the size of the land than in any other country but Scotland and Greece.

England has for hundreds of years been one of the leading powers of Europe, one of the great moving forces of the world, and, through her colonies, a veritable mother of nations; but her area is relatively very small. The area of the British Islands (121,700 sq. m.) is but 1 $\frac{1}{100}$ th of the surface of the world. The colonies and dependencies of the empire of which England is the centre cover a fifth of the land-area of the globe. England,

with an area of 50,874 sq. m., is considerably less than half the size of Rumania (122,282 sq. m.), less than a fourth of France (212,659 sq. m.), and is but little larger than the single state of New York (49,170 sq. m.); it is not a fifth of the size of Texas (265,896 sq. m.); and, indeed, twenty-eight of the states in the Union are each larger than England; several, in fact, much larger than the whole United Kingdom.

Her name 'this noble realm of England' owes to the *Engle* or Angles, who with the kindred Jutes and Saxons (*Seaxe*) descended on the greater part of what used to be known as Albion or Britain (see BRITANNIA), and conquered and occupied it in the 5th and following centuries (see ANGLES, ANGLO-SAXON). These kindred peoples all learned to call themselves *Englisc* or English, and by *Englaland* they understood the whole area now occupied by them—an area which in the 7th century extended over more than the half of the island, from the Forth to the English Channel. South-eastern Scotland, as occupied by the Angles, and not by Saxons or Jutes, was in the stricter sense English; and the people of the non-Celtic parts of Scotland, though now markedly differing from the southern English, are in blood and in mental and physical type at least as English in the wider sense as the people of Oxford or Kent. Political circumstances led the English and Anglicised Celts of North Britain beyond Solway and Tweed to become the subjects of the alien Scottish king, but their language they still called *Inglis*, as distinguished from the Erse of their Scottish or Gaelic fellow-countrymen.

The people of England constitute nearly three-fourths of the inhabitants of the British Islands; the English language in some form is that of all but a small minority; English literature is the common inheritance of the whole; the constitution and polity of England, slightly modified, is the British constitution under which the three kingdoms unitedly became glorious, and has been the original model for the free constitutions of all free peoples the whole world over. Hence it is not strange that not only by Englishmen, but also by many foreigners, the name of England is frequently used to designate not merely Great Britain and sometimes the British Islands, but even on occasion the entire British empire.

The physical features, as also the geology, of the British Islands are obviously so closely connected that it is convenient to treat of them collectively under the heads of GREAT BRITAIN and of IRELAND. General facts which concern the three kingdoms jointly are separately discussed under such heads as AGRICULTURE, ARMY, COLONIES, COUNTY, EDUCATION, EMIGRATION, NAVY, PARLIAMENT, RAILWAYS, &c. Here, on the other hand, some of the facts distinctive of England, which admit of being succinctly stated, may well be noted.

The area of England is 50,874 sq. m., so that, as the area of the British Islands, with Scotland, Wales, Ireland, Man, and the Channel Islands, is 121,700 sq. m., England alone covers about 42 per cent. of the whole. The population of England in 1650 is estimated to have been about 5,000,000, the increase up to that date having been slow. In 1750 it was probably 6,000,000. From that date the increase was rapid; in 1821 the population of England was 11,281,957; in 1831, 13,090,615; in 1841, 15,002,443; in 1851, 16,921,888; in 1861, 18,954,444; in 1871, 21,495,331; in 1881, 24,614,001; in 1891, 27,483,551; in 1901, 30,807,310; in 1911, 34,045,290; in 1921, 35,678,530. At the census of 1881, the population of England was 69·8 per cent. of the total population of the United Kingdom (35,241,482). England in 1921 made up about 76·6 per cent., or some three-fourths of the total population

(47,307,601, Irish figures being for 1911). The density of the population in England is greater than in any other corresponding European state except Saxony. In 1921 it was for England 701 per sq. m.; whereas for Scotland it was only 164 (in Saxony in 1919 it was 807). In England there were, in 1921, 43 towns with more than 100,000 inhabitants (in 1881, 20 such towns), in Scotland only 4, in Ireland 2. In England there were 96 above 50,000, in Scotland 11, in Ireland 3. At the census of 1921 the population of England, and of the administrative counties separately (including county boroughs within their boundaries) was as follows:

Counties	Area in statute acres (land and inland water)	Population
Bedfordshire	302,942	206,478
Berkshire	468,830	294,807
Buckinghamshire	479,360	236,209

The climate of Britain is insular and comparatively equable, milder on the whole than that of any region on the same northern parallel (see CLIMATE), with smaller extremes of heat and cold, with colder summers and warmer winters. England is milder than Scotland, and though moist compared with continental countries, less moist than Ireland. In spite of its dull skies and frequent rains, it was wisely said by Charles II. that the English climate 'invited men abroad more days in the year and more hours in the day than any other country.'

The situation of Britain has been shown to be in the very centre of the land-masses of the globe, a very great advantage for commerce and navigation; England, being nearer the European shores,

enjoys the advantage in higher measure than its sister-kingdoms. Its seas are less stormy, and it has a greatly more developed system of navigable rivers.

The north-west of England is mountainous and hilly, the east and south mainly a plain crossed by lines of low hills. The fertility of England is much greater than that of Scotland or Ireland, especially that of the wheat-bearing area of eastern England. The agriculturally productive area of England is estimated at 80 per cent. of its total, and of Wales 60 per cent., whereas that of Scotland is only 28·8 per cent., and of Ireland 74. England, whose surface has been said for variety to be an epitome of Europe, is very rich in minerals, of which coal and iron are incomparably the most important, making nine-tenths in value of the whole.

The people of England, as of other parts of the British Islands, are varied in physical character. Long skulls prevail to a much greater extent than among the neighbouring continental peoples. Besides the Nordic type, the Mediterranean is found, as well as intermediate long-heads. Some of these last, no doubt, result from crossing of Nordic and Mediterranean, but it is contended that others represent an undifferentiated long-headed population that has persisted from Aurignacian times. In the Neolithic and Bronze Ages immigrant broad-heads appear. Such were the beaker-folk or round-barrow men, who came probably from Galicia and Upper Silesia just before the Bronze Age began; the short-cist people; and perhaps a late Bronze Age Alpine people led by long-headed lords with leaf-shaped swords (see CHLTS). Among Iron Age new-comers were the Belgæ, probably tall, fair, moderately broad-headed people. The Roman Conquest brought many new elements. The Angles, Saxons, Jutes, Danes, and Northmen were mostly tall, fair, and long-headed. Some broad heads came in with the Conqueror; and since then peaceful immigration of all sorts has combined with other influences—industrialism, town-life, colonial enterprise, &c.—to modify the compound.

What is certain is that out of these various stocks a well-marked people has been formed, strenuous, self-reliant, resolute in defence of its rights, daring, laborious, industrious, and ambitious. Its essential character, with marked modifications, it has transmitted to the great daughter-nation of the United States, and to the colonies of Britain. And this race it is which has given its language and in part its institutions to over 150 millions of the world's inhabitants, and with the help of its Scottish and Irish kinsfolk has created for its and their offspring a glorious heritage in English literature. England became the classic land of liberty, where the power of the state, based on ancient precedent, was developed so as least to infringe on the freedom of the individual—a development sketched in the succeeding history, and continued on similar lines in the United States.

England became also the special home and headquarters of agricultural enterprise, mineral production, machine-making of all kinds and steam-power, of commerce, navigation, and shipping. England did not start in the race of commerce as early as many of those who are still her rivals. Long after France, Flanders, and parts of Germany were great manufacturing centres, England was an agricultural and pastoral country, wool its chief production and staple export. The woollen goods for its own use were mostly manufactured abroad. Edward I. did much to encourage such trade as there was in opening English ports to foreign merchants, and Edward III. induced many weavers, dyers, and fullers from Flanders to settle in

England. In the 14th century woollen cloth was manufactured at Bristol, London, and Norwich, and began to be exported. Linen and silk weaving became of some importance. Coal was exported from Newcastle to France in 1325; but it was later ere English cutlery was known abroad. Great progress took place in Elizabeth's reign. The reign of William III. marked a new era, for the immigration of French refugees after the revocation of the Edict of Nantes in 1685 soon told on the quality and amount of English manufactures. But the great and rapid advance which made the commerce and manufactures of England the wonder of the world dates from the latter half of the 18th century, and was largely owing to the unparalleled development of machinery, the use of steam as a motive power, improved communication, and later, steam-navigation and railways.

It is very observable that the local distribution of the great industries of England has changed very greatly since the 17th century. At the Revolution period, most of the greater towns of England were in the south and east; but these have now been long outstripped by northern rivals, and what were then important manufacturing towns have in many cases sunk into mere villages. After London, the chief towns were Bristol and Norwich, each with some 29,000 inhabitants. Exeter with 10,000 was probably equalled by York. Worcester and Nottingham may be set down at 8000; while Leeds had but 7000, Manchester hardly 6000, Birmingham, Sheffield, and Liverpool perhaps less than 4000. Now English manufacturing industries have most of their special seats in the north. If we draw a line from the mouth of the Severn to the Wash, we find that to the south-east there are hardly twenty towns, not seaports or suburbs of London, which have a population exceeding 25,000; to the north-west of the line there are about a hundred inland towns of that size. It is very significant that all the coal of England is found north of the line named, about or near the populous money-making towns.

In no way can a better conception be formed of the state of England at different periods than from the works of topographers, foreign visitors, &c., such as Leland and Camden for the 16th century; Drayton and Fuller for the 17th; Defoe, Pennant, Pococke, Moritz, and Young for the 18th; Cobbett, Emerson, Hawthorne, Esquiros, Taine, Kohl, and Burroughs for the 19th. See also Escott, *England: her People, Polity, and Pursuits* (1879; 2d ed. 1886); W. Cunningham, *Growth of English Industry* (1882; 4th ed. 1905); *Social England*, edited by Trail (1893-96); H. de B. Gibbins, *Industry in England* (1912); G. H. Perris, *Industrial History of Modern England* (1920); Beddoe, *Races of Britain* (1885); Fleure, *Races of England and Wales* (1923).

HISTORY OF ENGLAND.

Though the history of England cannot properly be said to begin till the 5th century, when the Teutonic tribes who have given the country its name established themselves in the island, it is of some importance to understand the condition of the people whom they supplanted. There can be little doubt that, speaking generally, the inhabitants of the island when conquered by the Romans were of Celtic origin. They were not indeed entirely homogeneous; two distinct branches of the Celtic language were spoken, the Gauls of France are mentioned by Cæsar as having exercised authority over the island, the Belgæ had certainly established themselves there, and certain tribe-names lead to the belief that men of Teutonic origin had already formed settlements. The island lying at the extremity of Europe had probably formed a natural refuge for tribes driven from their own lands, and a natural prey of those in search of new homes.

But on the whole there can be little question that the population was Celtic. It had passed beyond the age of barbarism, and when Claudius determined to complete the conquest which Cæsar's temporary raid in 55 B.C. had foreshadowed, some sort of general confederacy was in existence, a king of the name of Cunobelin reigned at Camulodunum, near Colchester, and the existence of not less than forty varieties of his coins bear witness to the greatness of his influence and the comparative civilisation of his rule. His son, Caractacus, and, eleven years later, Boadicea, queen of the Iceni, opposed a long and terrible resistance to the Roman arms; but the arrival of Agricola in 78, and his eight years of wise government, brought the country at length into the condition of a Roman province. The conquest of the whole island was, however, never completed. It seemed good to the Romans to limit their successes, and to attempt by great defensive works to exclude from their dominions the still unconquered Celts of the north. Lines were erected between the Firths of Forth and Clyde, and between Bowness and the mouth of the Tyne. The intermediate district was a scene of constant warfare, both lines were from time to time strengthened, and the more southern of the two changed during the 4th century into the great Roman Wall (see **HADRIAN'S WALL**). Within this limit the occupation of the country was complete. For two centuries it was probably merely a military occupation, and at no time does it appear that there were more than 20,000 Roman soldiers in the province; but as time passed on it appears certain that the influence of the conquerors became largely felt. Towns, the remains of which still exist, were built, bringing with them of necessity the close intercourse of trade, and numerous traces of villas in many parts of the country show the spread of peaceful Roman life. It was the policy of Rome in its provinces to debar the middle classes from the use of arms, and though possibly, as in India at present, the native nobles and princes were allowed to keep in some degree their rank, it was under the shelter of the Roman legions that civilisation advanced, and upon their prowess that safety from the threatened encroachments of unconquered Celts or marauding Teutons was secured. It is impossible to say how far civilisation had extended, or how far the language had been influenced by the Roman occupation. The close resemblance of many common agricultural terms, of the names of plants, and so on, to Latin words would lead to the belief that the language was Latinised. On the other hand, local names, the names of woods, mountains, and rivers, are largely Celtic. It seems not improbable that both high civilisation and Roman speech were chiefly concentrated along the great roads, and round the cities and stations with which these were lined.

The disturbances of the empire, and the danger which threatened it from the pressure of the outlying barbarians, compelled in 411 the withdrawal of the legions; and the half-Romanised inhabitants who had learned to rest on the support and valour of their conquerors were left to their own resources to withstand the unconquered Celts of the north, now known as Picts, and their piratical allies the Irish Scots. The movement of the barbarians had affected the people on the borders of the North Sea; the Jutes from Jutland, the Angles from Sleswick, the Saxons from Holstein and the neighbouring coasts were covering the sea with their expeditions. Summoned to the assistance of the civilised Britons, a party of Jutes found means to establish themselves in Kent. It was an example readily followed. Before the year 600 Saxons and Angles had formed settlements extending as far northward as the Forth. About that year the various princedoms

may be regarded as merged in two considerable and rival powers, Northumbria and Kent; while a third, Wessex, fated ultimately to devour the other two, lay along the south, at present interested in extending its power westward. It still remains a question whether the invaders destroyed the conquered inhabitants or not. On the strength of certain expressions in the chronicler Gildas it has been held that no quarter was shown; but it is more probable that, as in other cases of conquest, the invaders settled down in the midst of the conquered population, content to rule as manorial lords over their own free followers and the slaves and dependents of their predecessors.

It was long before the various settlements of the Saxons were fused into one. Long before political union was reached, the unity of the people found expression in a single Christian church. While the powers of Northumbria and Kent were still balanced, the marriage of the king of Kent with a Frankish princess offered an opportunity for the evangelisation of the country. Augustine and his fellow-missionaries landed in Thanet in 596, and, well received by the king, found a home in Canterbury. A similar circumstance brought Christianity to the north; a Kentish princess married to Edwin of Northumbria took with her Paulinus, and established Christianity in York. The change of religion went near to destroying the Northumbrian power. Heathenism found a champion, and Penda, uniting the central tribes into the kingdom of Mercia, for a while established his supremacy over Northumbria, and drove the Roman priesthood to flight. The gap thus left was supplied by the devoted missionaries of the Celtic Church settled in Lindisfarne. But the restoration of the Northumbrian power was fatal alike to heathenism and to the Celtic Church. After the Council of Whitby in 664, the Roman Church regained predominance, and was organised in a single archiepiscopal see by Theodore of Tarsus, holding his appointment from Rome. After the fall of Penda, the supremacy of the northern kingdom was unquestioned, till some sixty years later it gave way to Mercia. About the year 800, however, both Mercia and Northumbria had to yield to the third power. Egbert, king of Wessex, who had seen something of centralisation in the court of Charlemagne, during the thirty-six years of his reign gradually brought under his power all the English kingdoms, whether Anglian or Saxon, and continuing the hereditary struggle of his people with the British populations, established a permanent superiority over all England, with the exception of the Britons north of the Dee.

But already an enemy had made its appearance to which the newly centralised kingdom was to yield. The Danes, issuing from the Scandinavian coasts, had before the death of Egbert begun to harry the country. At first as robbers, then as settlers, and finally as conquerors, for two centuries they occupy English history. During the reign of Ethelred their incessant but isolated incursions assumed the form of an invasion, East Anglia passed into their hands, and their leader, Guthrum, took to himself the title of king. For seven years Alfred on the throne of Wessex carried on a deadly struggle with this rival power, and at length concluded a treaty of partition at the Peace of Wedmore (878), surrendering to the Danes the north and east of England to be held by them as vassals of the Saxon king. The supremacy of Wessex was thus secured, and ripened in the following reigns into something little short of an imperial authority. Edward the Elder was not only recognised as the overlord of Mercia and Northumbria, but the Welsh kings swore alliance, and the kings of Scotland and Strathclyde acknowledged him as their father and

lord; he treated on equal terms and contracted marriage alliances with the greatest princes of Europe. His position was fully vindicated by his son Æthelstan, under whom, perhaps, the West Saxon monarchy reached its highest point of greatness. The decisive battle of Brunanburh, in 937, won over a complicated confederation, dealt a death-blow to all opponents. The reign of Edgar the Peaceful, and the government of his great minister Dunstan, closed the period of Saxon greatness. From this time onwards weak kings, factious nobles, and a broken organisation were unable to resist the renewed incursions of the Scandinavian tribes. The jealousies between the various sections of the people, restrained by the strong central authority of the late kings, broke out afresh. The northern kingdoms where Danish law prevailed afforded a natural support for the invaders. The alliance of King Ethelred with the Normans, and his marriage with Emma, a Norman princess, only added a fresh element of weakness by the presence of her foreign followers. Recourse was had in vain to large payments to the Danes, and to the cruel and treacherous murder, on St Brice's Day, 1002, of the Danes settled in Wessex. Ten years later all opposition had been overcome, and Sweyn, the leader of the invaders, was practically king of England. He was succeeded by his son Canute, and though a brief outburst of vigour under Edmund Ironside enabled the English to secure a division of the country, the death of their leader compelled them to submit to Canute. Under its Danish king England was ably ruled, and was in some respects the head of a Scandinavian empire. But Canute's two sons failed to continue their father's work. Opportunity was allowed for the rise of Godwine, Earl of Wessex, and on the death of Hardicanute in 1042, Edward the Confessor, the son of Ethelred, resting on the support of the great earl, re-established the house of Cerdic on the throne. Educated in Normandy, he surrounded himself with foreign friends, and filled the high places of the kingdom with Frenchmen. As leader and representative of the national feeling, Godwine succeeded after a while in driving the foreigners from the country, and establishing himself in a predominant position over the south of England. In the north the influence of the earls of Mercia prevented his absolute supremacy. He handed on both his power and his rivalry with the northern earls to his son Harold. Successful against his rivals, Harold placed most of the earldoms in the hands of his brothers. So completely was he recognised as the first of Englishmen, that upon the death of the king the Witan (see WITENAGEMÓT) had no hesitation in electing him to the throne.

In thus choosing a king from beyond the limits of the royal family the Witan had transgressed a well-established English custom. A formidable rival claimant at once appeared. William, Duke of Normandy, a cousin of the late king, demanded the throne as next of kin, and pleaded the promise of the Confessor. A second enemy threatened Harold: his brother Tostig had proved a traitor and had been banished; he now returned in company with the Norwegian fleet. The northern earls opposed him, and Harold, hastening to their assistance, won the battle of Stamford Bridge over the invaders. But the decentralised character of the English constitution and the strength of family rivalry made lengthened union impossible. When, three days after, on the 28th of September 1066, the Norman duke landed at Pevensey, it was single-handed and with hastily collected forces that Harold met him. The great battle of Senlac, near Hastings, was decisive, Harold and his brothers were slain, and England was left without a king. Again the jealousy

between Wessex and Mercia prevented either a combined national opposition or the election to the throne of a native prince. William had little difficulty in slipping into the vacant post and securing his election by the Witan. The series of local efforts at opposition which followed his election proved unsuccessful, and by 1070 his authority was recognised throughout the country.

The change of dynasty thus effected connected England with the great movements of the Continent. Up to this time it had been somewhat isolated. Though its church was in communion with Rome, and had frequent intercourse with it, it was distinctly a national church; though feudalism was rapidly advancing, it had pursued an independent and national course of development. It was in some degree as the champion of the great system of Western Christianity that William had put forward his claims, and he brought with him followers imbued with all the principles and forms of continental feudalism. All the varieties of class and of land tenure which had arisen spontaneously in England were now assimilated to those existing where complete feudalism was in force; the connection with Rome was ratified by an entire change in the episcopate. But William had no idea of assuming the position of a chief among equals, or of subordinating his authority to that of the church. He found in the organisation of the conquered kingdom principles which enabled him, while using feudal language, to be in fact an absolute king, and to set such limits to the power of Rome as to keep the church virtually in subordination. The Norman kings, when not engrossed in foreign enterprises, were occupied in establishing, in opposition to the nobility and the church, that powerful monarchy which the Conqueror had established. They found in the old institution of the national militia an instrument with which to oppose the feudal levies of the barons. An administrative system centred in the crown, and working chiefly through the machinery of the exchequer, went far to centralise the government. Triumphant suppression of insurrections enabled them to get rid of the feudal baronage of the Conquest, while a new nobility of administrative origin and attached to the national system gradually took its place. But the death of Henry I. leaving only a daughter, Matilda, gave room for a disputed succession. All the discordant elements which the royal power had held in repression burst into life. The reign of Stephen was a time of constant civil war, during which the nation learned from the intolerable tyranny under which it groaned the value of the repressing hand of royalty. The miserable time was brought to a close chiefly by the mediation of the church. Matilda's son Henry, already a powerful prince in France, was accepted as the heir to the throne, and practically intrusted with the restoration of order. It was with the general concurrence of the nation that he was able to re-establish upon a broader and better basis the powerful monarchy of his predecessors. A series of great administrative reforms brought justice and finance into the hands of the king and his intimate council or Curia Regis, and went far to break through the quasi-independence of the land-owners. The suppression of a great insurrection affecting all his possessions, and supported by the kings of France and Scotland, left him unquestioned master of his kingdom so far as the baronage was concerned. His attempts to reduce the church to subordination were less successful; the opposition of Becket to the enactments of the Council of Clarendon produced a disastrous struggle with Rome. But though technically worsted, Henry's power suffered no serious diminution from his defeat. He handed

on to his son a powerful and well-organised monarchy, in which the feeling of national unity had made great advances. His system proved strong enough to support the continued absence of Richard in the Crusades and in his French dominions; national life even acquired increased strength by the self-government which was thus forced on the administration.

In the hands of Richard's successor the evil effects of the enormous power concentrated in the crown became obvious. Boastful, tyrannical, and weak, John excited the anger of all classes. The disgrace he brought upon England, the shock thus given to the rising feeling of national pride, afforded an opportunity for the exhibition of the discontent he had roused. He allowed himself to be stripped of all his French possessions; he plunged into a struggle with the Papal See, was excommunicated and deposed, and formally surrendered his crown into the hands of the pope. The nobility, freed from connection with the Continent and supported by all parties smarting alike from the evils of misgovernment and the shame of disaster, appeared as the true leaders of the nation, and wrung from the humbled king that great charter which secured, in the form of a solemn treaty, the foundations of the future liberties of England. To make the charter a reality, and to secure the orderly development of these liberties, was the work of the great king Edward I. John's compact with the people proved insufficient to restrain the personal and capricious exercise of the royal power in the hands of his son, Henry III. The surrender of the crown proved more of a reality than was expected; the Papal See, unable to establish a temporal suzerainty, mercilessly fleeced the people and the church, and the country was filled as of old with foreigners, on whom wealth and high places were lavished. The finances fell into utter decay. At length a demand for money to support, in the interest of Rome, the claims of the king's son to the throne of Sicily brought matters to a crisis, and in 1258 the barons passed the Provisions of Oxford, drove Henry's foreign friends from the kingdom, and virtually superseded the crown by a committee of government. Henry's attempts to break from the restrictions laid on him produced an armed insurrection, and Simon de Montfort, at the head of the barons and the commonalty of the towns, defeating the royal forces at Lewes, established a revolutionary government of which he was practically the master. But the jealousy with which the nobility regarded the rise of Montfort allowed Edward the Prince of Wales to come forward as the leader of a party at once conservative and reforming. His accession to the throne gave him an opportunity of carrying out his views. In the parliament of 1295, a complete assembly of all estates, he gathered into a national centre all the scattered elements of representation and self-government which had long existed in the county courts. The principle that where all were concerned all should have a voice was acknowledged, and the national liberties were placed in the charge of an assembly in which all orders were included. At the same time the position of the crown was maintained and rendered effective by the large powers still left in the hands of the king's council. For many years the struggle between parliament and prerogative remained undecided; but armed with the power of taxation, and taking advantage of the wants or weaknesses of the sovereign, the parliament continued to make good its position as the national council. At the close of Edward III.'s reign it was able to attack and impeach the ministry. The success of Richard II. in ridding himself of the influence of his uncles by

which his youth had been surrounded, and his vehement assertion of the powers of the crown, produced a revolution which closed the struggle, and Henry IV. came to the throne with a parliamentary title, while the council nominated in parliament became in fact a body of national ministers.

The rise of parliament had gone hand in hand with the assertion of national life. Edward I. had not only marked out the lines the constitution was to follow, he had rid England of foreign influences. Busying himself but little with the Continent, he had devoted his attention to the conquest of Wales and Scotland. His death before the completion of his conquest of the northern kingdom allowed the Scots to inflict a final defeat upon his weaker son at Bannockburn. But the national feeling of the English, in abeyance during the political disturbances of Edward II.'s reign, reasserted itself in the ambitious efforts of Edward III. to place himself upon the throne of France, and was strengthened by the brilliant victories which attended them. Though the victories were useless, and the war a series of raids rather than a well-considered conquest, the effects at home were of great importance. The continual want of money forced the crown to frequent concessions to the parliament; the spirit of the people was raised by success; and the life of the soldier played an important part in liberating the lower orders from serfdom. The villeinage of earlier times had been gradually declining, and rent and wages were taking the place of villein tenure and forced service. The terrible ravages of the Black Death upset for a while the economic arrangements of the country, and the attempt to drive back the liberated serf to his old position caused the great rising of Wat Tyler in 1381. The insurrection was suppressed, but a death-blow was practically dealt to serfdom. In close connection with this upheaval of the working-classes was the movement in opposition to the church. The doctrines of Wyclif and the Lollards, so much in harmony with the democratic movement, could not fail largely to influence it, and for a while hostility to the church played a considerable part in parliamentary history.

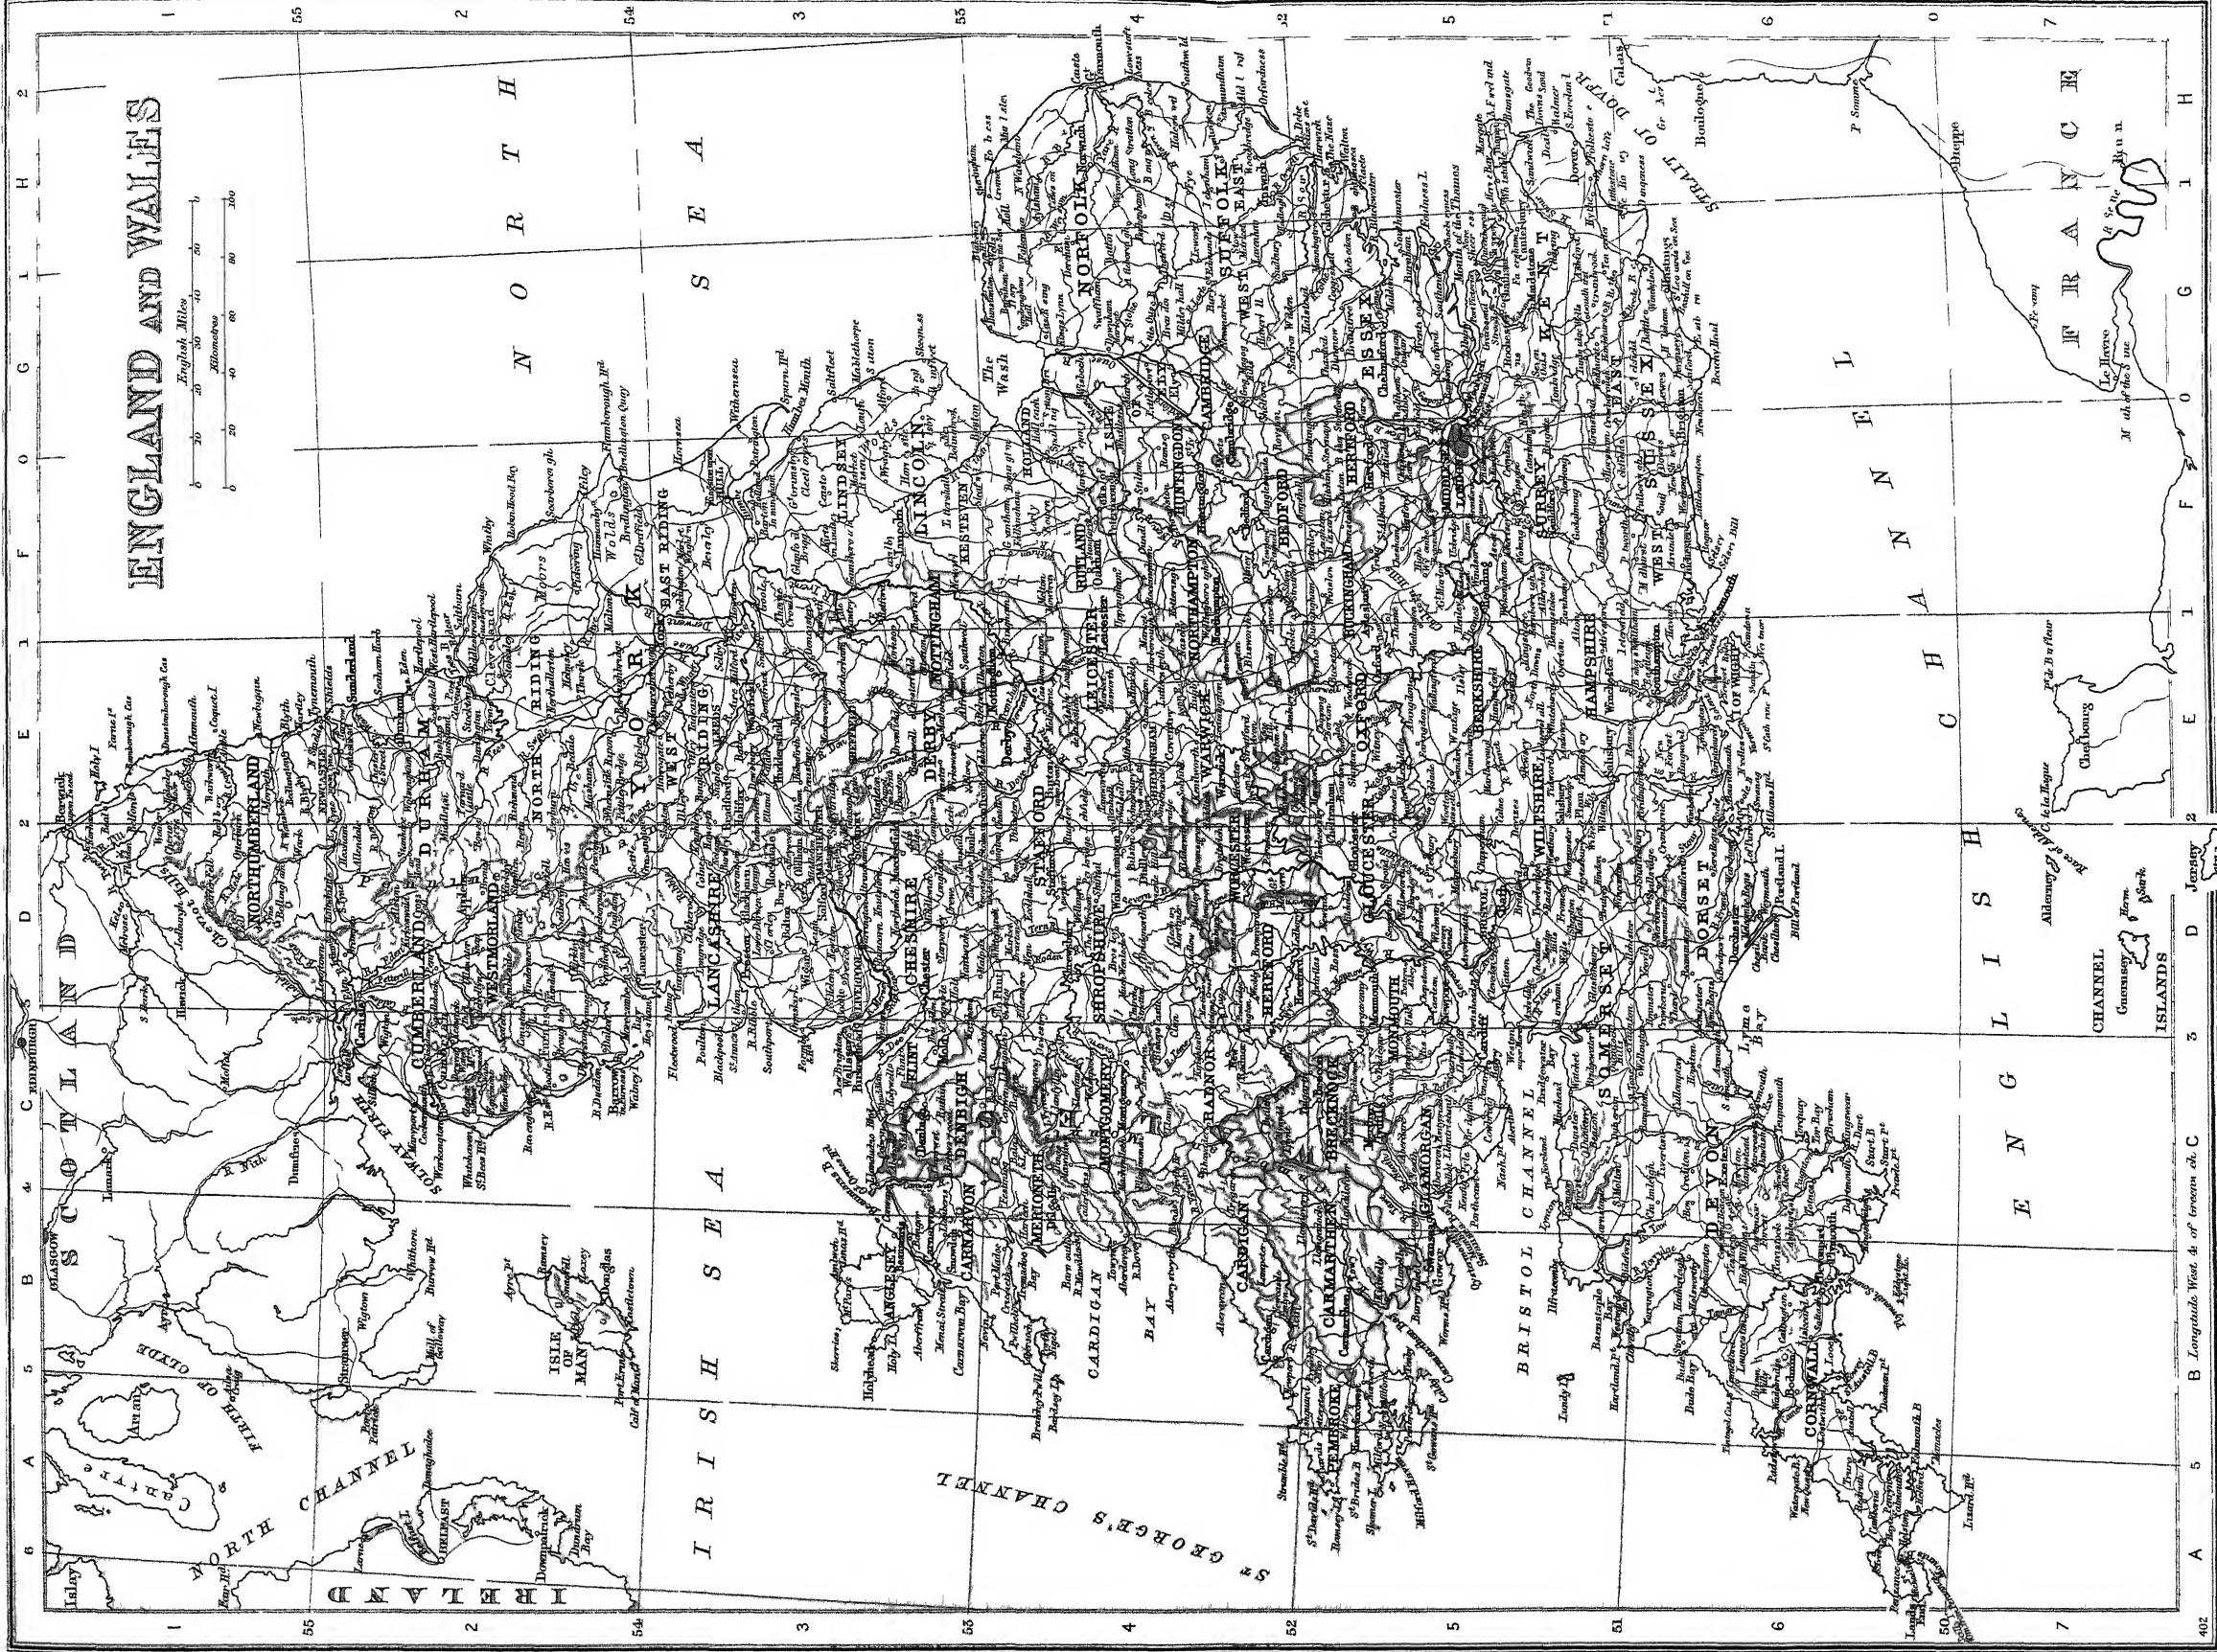

The completion of the constitutional system marked by the accession of Henry IV. did not prevent the recurrence of disorder, but during the reign of his son full harmony existed between the king and people. The disturbances which had broken out in France afforded an opportunity for renewing the war, and Henry V. found no difficulty in carrying the people with him in his victorious attacks upon that country. A statesman as well as a conqueror, his progress was very different from that of Edward III. The Treaty of Troyes seemed to promise the ultimate union of the two kingdoms, but the work of consolidation was scarcely begun when the great king died, intimating to those who should carry on the work that the occupation of Normandy should be the limit of their aims. The foreign success and domestic harmony was of short duration. Though the power of the nobles as feudalists had disappeared, they were still too strong to accept easily the co-operation of the other orders in a national system except from the hands of a powerful ruler. Their strength had been increased by the great position given to the royal princes. The parliamentary establishment of the younger branch upon the throne had opened the door to the rival claims of hereditary succession. A strong government was scarcely possible during the infancy of Henry VI., especially as the council of regency found in the Duke of Gloucester, a man of ill-regulated ambition, an opponent with whom it was difficult to deal. His greater brother, the Duke of Bedford, devoted himself chiefly to the affairs of France, and though he had succeeded in maintaining some

degree of order in England, his early death was the signal for an outbreak with which the council and subsequently the young king proved unable to cope. Continual disaster in France still further discredited the government. Taking advantage of the claim of hereditary right, the Duke of York came forward as the champion of order. The nobility ranged themselves on one side or the other of the contending parties, and the country became the seat of a cruel dynastic war. The Yorkists were victorious in the struggle. The death of their old and moderate leader placed at their head his son Edward, a man of great ability imbued with the morality and principles of an Italian despot, and as the long regency had inevitably replaced in the hands of the council much of its independent power, Edward IV. found little difficulty in employing it for his own purposes. Parliament ceased to have much importance except to register the sovereign's will or to grant submissively the taxes he required. In the earlier struggles for national liberty the king had found his chief opponent in the baronage, and subsequently as leaders of the nation the nobles had exercised a great restraining influence. But in the internecine struggle of the Wars of the Roses they had committed political suicide, and Edward IV., surrounded by a nobility of his own creation, and armed with the powers of prerogative, which had never been formally abrogated, found himself able to establish a practical absolutism. The family dispute had not, however, reached its last act; Edward's successor, Richard III., rendered himself odious to all classes of the people, and the battle of Bosworth placed upon the throne a prince who claimed to be a representative of the Lancastrian House, and whose position was so far less absolute than his predecessors that he acknowledged that he was king by the will of the people.

The accession of Henry VII. and the Tudor House opens the second act of the drama of English history. The great principles of the middle ages had passed away; it was the age of the rebirth of learning; printing had been invented; firearms were superseding the lance and bow; the discovery of the western world was soon to excite the spirit of nautical enterprise; capital was taking the place of the restricted guild system; the inclosure of commons was changing the face of the country, depopulating the fields and filling the cities; the church had begun to be shaken from its foundations. In the midst of this changed society the new dynasty had ascended the throne, claiming to rest upon the popular will, but invested with all the absolute authority with which the late reigns had surrounded the crown. It is not perhaps going too far to say that the king was endowed with a temporary dictatorship. The typical representative of this phase of government is Henry VIII., a man in whom gross passion and unscrupulous determination to gratify his own will were curiously blended with a certain amount of culture and a real desire for the well-being of his people. Charged as it were with the duty of re-establishing an orderly national life upon a strong monarchical basis, he plunged into war as a ready means of asserting national power. France and Spain were already on the threshold of their great struggle for the supremacy of Europe, and it was in strict accordance with the tradition of English policy that Henry allied himself with the Spanish house. But a change was speedily to pass over the foreign relations of England. Instigated by his passion for Anne Boleyn, Henry demanded a divorce from his Spanish wife; the opposition of the papacy precipitated the Reformation in England, and transferred the national hostility from France to Spain. The difficulties he encountered in his pursuit of the divorce brought him face to

face with the one weak point in his position as absolute monarch. The possibility of the assertion of paramount authority by a foreign prince had been studiously hidden from him by his ecclesiastical minister Cardinal Wolsey, who, himself master of the church, had thought to avoid all contest of authorities by devoting his power to the service of the crown. Such a possibility was now suddenly revealed to him. The fall of Wolsey and the substitution in his place of Thomas Cromwell supplied the king with a very able instrument for a high-handed assertion of the independence of the English Church. The movement found support in the excited animosity to the doctrines and practice of Rome which was filling Europe. Led by the energy of Cromwell, Henry proceeded beyond mere separation to the destruction of much of the apparatus of the old church. Reformed liturgies, an English Bible, the dissolution of the monasteries, seemed to secure a triumph for the advanced reformers. But the minister had overshot the desire of his master, and the reign closed amid Henry's efforts by even-handed severity to establish the supremacy of the crown without allowing the predominance of either party. So delicate an equilibrium could not be maintained. A burst of reforming zeal, supported by ministers of questionable character and still more questionable prudence, went far to destroy the position of England; and it was not without a very general consensus in her favour that Mary, the champion of the old faith, ascended the throne. Unfortunately, her birth and natural prejudices led her to ally herself closely with Spain. A great reaction in favour of Roman Catholicism throughout Europe had begun; Spain was at the head of the movement, and there seemed every probability that England would lose its national independence and be bound not only to the ecclesiastical supremacy of Rome, but to the temporal supremacy of Spain. Religious persecutions of a severity unknown in England added strength to the angry feelings then excited. Protestantism and national independence were forced into connection, and it became the inevitable duty of Elizabeth on her accession to play her part as the supporter of this twofold cause. With the aid of her great minister Lord Burghley, she acted with consummate ability. Far too weak to oppose at once the powerful forces of united Catholicism, she contrived by a temporising policy to avoid the dangers which would have attended an open defiance. She took advantage abroad of every opening for indirect support of the Protestant cause; at home, skilfully mingling politics and religion, without direct religious persecution she treated her opponents as traitors. She encouraged with all her woman's wit the feeling for nautical enterprise which was rife in the country; and at length, with the obstacles which had met her early course removed, firmly seated on her throne, and regarded both at home and abroad as the champion of Protestantism, she was able to bid defiance to the power of Spain and establish the supremacy of the English navy in the repulse of the Spanish Armada.

In carrying out the sweeping changes of his reign, Henry VIII. had found the support of his people necessary. Even the settlement of the succession, though intrusted to Henry and carried out according to his wish, was arranged with parliamentary sanction. The co-operation of the people was still more necessary for Elizabeth. Throughout her reign the influence of parliament had been rising. Social changes had still further tended in this direction; if the old nobility had chiefly disappeared, a new nobility had taken its place, and the gentlemen of England, with property often increased from the monastic spoils, had become an important class. Though Elizabeth constantly

assumed a masterful position with regard to her parliaments, she none the less listened to them and at times yielded to their remonstrances. It remained for the House of Stuart to force by unwise opposition this rising power into a position of supremacy. The death of the Virgin Queen seemed likely to open the question of the succession, but the crown passed without difficulty to the Scottish king, and the long-delayed union of the two kingdoms under one ruler was accomplished. The parliamentary settlement of Henry VIII. had set aside the Scottish line; it was therefore by strict law of inheritance only that James found himself called to the throne. Trained in a different school of politics, and apparently succeeding by what it was the fashion of the time to speak of as 'divine right,' he failed entirely to understand the position of his predecessors. This miscomprehension of his historical position handed on to his descendants was the cause of the disasters which attended their dynasty. Conceiving themselves possessed of the powers inherent in the old English crown, and determined to make them good, they forced the nation to fight over again the battle which had already been decided in the time of the Lancastrians. The contest between personal monarchy and constitutional government was terminated only by the removal of the Stuarts from the throne. A battlefield was found in nearly every department of government. James I. himself ran counter to many of the national prejudices. Thoroughly Protestant at heart, he favoured the new High Church party, who looked for support in a powerful crown; easily influenced by favourites, he fell in with the fashion of the monarchies abroad, and ruled through the hands of a great minister; in disregard of the wishes of the nation, he contracted a friendship for Spain, which was now regarded as the hereditary foe. But his weaknesses were not untempered by sagacity, and he succeeded in avoiding any overt breach with his people. His more obstinate son was less fortunate. From the beginning of his reign he found his parliament arrayed against him; it succeeded even in wringing from him the great Petition of Right. Weary of the struggle in which he seemed to be worsted, he believed himself strong enough to stand alone, and for some years ruled without a parliament and in disregard of the most important liberties of his subjects. Financial difficulties, caused in part by his ill-advised efforts to establish the Episcopalian form of worship in his northern kingdom, compelled him at length to seek parliamentary aid. The long-repressed discontent of the nation thus found a means of expression, and the edifice of personal government fell before it. A grudging consent to hotly pressed reforms, an unfortunate laxity in observing his promises, and unwise efforts at resuming his power drove Charles into open hostility with the people, and the country was plunged into the horrors of civil war. Revolution ran its inevitable course; the constitutional leaders of the early movement gave place to men who dreamed of much more radical changes, and whose politics were deeply tinged with religious fervour. The war brought to the surface successful generals, and in one of them was found a man who united vast practical ability with the subversive views and religious enthusiasm of the advanced party.

The parliamentary enemies of Charles, having completed their work by the execution of the king, found themselves mastered by the overwhelming ability of Oliver Cromwell. Raised to what was practically the throne, he set himself to reconstitute upon a new basis the constitutional structure which had been swept away. His large and tolerant views, and his determination to produce order, excited the hostility of the narrow sectarians who

had formed the majority of the Long Parliament. By all men of conservative mind, or who shared in the loyal sentiment so prevalent among Englishmen, he was regarded with aversion. His efforts to bring well-ordered liberty out of the jarring elements with which he was surrounded failed; he was forced throughout his tenure of power to rely upon his own iron will. He succeeded in raising England to a high place among nations; it again assumed the position of leader of the Protestant interest, and again sought its allies among the enemies of Spain. But on the death of the great Protector, and at the prospect of a succession of military tyrannies, a wave of reaction swept over the country. Enthusiasm had died out, and that majority which at all times loves the old ways and prefers the easy paths of habit to the strenuous effort necessary to complete reforms insisted on the restoration of the banished house. With general acclamation, though not without some attempts to restrain his power within legitimate limits, Charles II. was brought back to Whitehall. Less arbitrary than his father, and far more capable of bending to the storm, he proved no less determined to maintain in his own way the fullness of the power he had inherited. He had to contend with much more formidable opponents. Though the full restoration of the church and crown had followed upon his accession, the Rebellion had not been without permanent results. It was impossible that the parliament which had for years been regarded as the source of government should sink back into the position it had occupied in the reign of Charles I.; the king could no longer hope to rule without it or to raise the revenue from illegitimate sources. The reign was one long dispute. The character of Charles, licentious, extravagant, and ready to waste the national resources upon his own pleasures, afforded ample ground of complaint. Surrounded by advisers as unscrupulous as himself, he sold himself to the French king to supply his financial wants. At the instigation of his paymaster, he plunged the country into a disastrous war with its Protestant neighbour Holland, and by his mismanagement allowed the enemy's fleet to ride undisturbed at the very threshold of the capital. He tampered with the national credit, and attempted by an exercise of high prerogative to set aside the laws against the Catholics. The enthusiastic parliament elected upon his return became before the close of its long life his bitter opponent.

The assaults of the opposition, Whigs as they were now called, were directed against the Duke of York, the king's Roman Catholic brother. Nothing would satisfy them but his absolute exclusion from the throne. To bring discredit upon the Catholics they were not ashamed to lend themselves to the infamous perjuries of Titus Oates. They thought of placing the king's illegitimate son, the Duke of Monmouth, upon the throne; but their insolence defeated itself. Charles, never deficient in political insight, understood the national love for the rights of legitimacy, the dread of a disputed succession, and the sympathy with which his efforts to support his brother were regarded. He dissolved his refractory parliament, and even thought of vengeance. He drove Shaftesbury, the leader of the opposition, from the country, and assaulted the strongholds of his enemies by finding excuses to confiscate the charters of London and other great cities. The Whigs, who saw that such a step by changing the constituencies might easily change the character of future parliaments, were driven to despair. The more statesmanlike among them began to think of seeking for the assistance of the king's nephew, the Prince of Orange. Some of the wilder spirits sought for a speedier remedy in assassination. The discovery

and punishment of the Rye-house Plot, and the skilful mingling of the aspirations of patriots with the atrocious schemes of vulgar murderers, for a while discredited the Whigs, and Charles died to all appearance triumphant. It remained for his brother to bring into action the deep-seated discontent which underlay the seeming success of the crown. With a want of judgment little short of judicial blindness, he proceeded in a few years to alienate every class in England. The open insurrections of Monmouth and Argyll were punished with reckless and bloody severity. The Test Acts were set at defiance, and Catholics filled the army. He maintained the shameful attitude his brother had adopted towards France. He laid his hand upon the freehold offices of the universities and the church, asserted the power of the crown to dispense with statutes, re-established the court of High Commission, called upon the clergy to read publicly his illegal declaration of religious indulgence, and established a standing army to overawe the capital. Such a series of tyrannical actions brought about the crisis. The Whig leaders betook themselves to William of Orange. This great statesman, who had devoted his life to restrain within due limits the power of Louis XIV., at once accepted with joy the opportunity of adding the strength of England to his great combinations. Protestant in religion, tolerant both by nature and by political necessity, the powerful chief of a republican government, he was well fitted to rule a kingdom torn by religious and political faction. The heads of all the English parties had sought his aid; his mere appearance was sufficient to close the Stuart dynasty and drive James a fugitive from the country.

The nation had again entered upon the full exercise of its powers. Taught by experience, before it deposited them in the hands of the king, it formulated the liberties of the country in a great and binding charter which should at once and for ever put an end to those efforts at personal rule which had rendered its previous history so stormy. The victory of parliament was thus completed. The reign of the first parliamentary king was indeed disturbed throughout by conspiracies, and rendered unrestful by the efforts of the exiled house, and at the close of the reign of Queen Anne for one critical moment there was a possibility that the Tories under Bolingbroke would succeed in re-establishing the Stuarts; but the rapid action of the great Whig nobles thwarted the attempt, and the failure of the Jacobite insurrection in 1715 secured in accordance with the settlement of parliament the Hanoverian House upon the throne. From that time onward, through the reigns of the four Georges, William IV., Victoria, Edward VII., and George V., constitutional government has constantly prevailed. The contests of parties, however severe, have been over differences of opinion of a less vital character than those involved in a change of dynasty. It has been possible, without revolution, without impeachment, to allow of the quiet and orderly change of ministers as a regular part of the working of the parliamentary machine. Such a process implies little short of the complete disappearance of the personal wishes or opinions of the monarch, as a factor in the political life of the nation. It was not without resistance that the crown consented to assume this attitude. Neither William III. nor the statesmen who had secured his accession understood the full results of what had been done. Nor was William himself, bent upon using the wealth of his new dominions to aid him in his great continental schemes, inclined to resign any of the powers of the crown or to throw himself into the arms of a single party; he attempted, like his predecessors, to employ as his ministers the ablest men of all parties. It was

almost by accident that what is known as 'party government,' by which the king chooses his ministers from the majority in the House of Commons, and thus puts himself in harmony with his parliament, was discovered. The lesson which the success attending the great Whig government of 1696 taught was strengthened by experience. It was not till the Duke of Marlborough, the heir of the views and objects of William, found himself supported by the homogeneous ministry of 1708, that he met with unqualified success. From that time the ministry, virtually a committee of the majority of the house, and known as the Cabinet, has formed a recognised part of the machinery of government.

But it was not only in the establishment of constitutional government that the Revolution of 1688 produced a change in the attitude of England. It introduced the country as a first-rate power into the politics of Europe; no important complications have since arisen in which it has not played its part. Throughout William's reign, as a matter of course, its strength was employed against France. The war of the Spanish Succession opened to its armies under the leading of Marlborough a glorious career of victory. The Whig leaders, who had not shrunk from impeaching the authors of the Peace of Utrecht which closed it, yet appropriated the advantages then acquired, and forced England in support of the treaty to the very head of the European powers. In the war of the Austrian Succession, the national energies, directed chiefly against France, secured British supremacy upon the ocean, which ripened under the great Pitt in his alliance with Frederick of Prussia into the unquestioned command of the colonial world both in the east and west. Though paralysed for a moment by the disasters of the American rebellion, the military enterprise of the country revived under the younger Pitt. Forced into opposition to the French Revolution, he was the soul of the great coalitions by which the proselytising vehemence of the Jacobins was held in check. The appearance of Napoleon upon the scene, and the extraordinary successes which attended his arms, changed the character of the war; it became a struggle for existence. It was again English subsidies, English troops, and English successes in Spain which tended more than anything else to bring the great powers into action, and to rouse that feeling of national life which produced the overthrow of the Napoleonic empire. Once again England stood at the very head of European powers.

One cause of these vast successes, unexpected in a country under popular rule, is to be found in the character of the government which sprang from the Revolution. That event was in its essence an aristocratic rather than a popular movement. The restriction of the constituencies and the influence of the possession of land threw power into the hands of a comparatively limited class. It was more as an oligarchy than as a democracy that England was able to prove itself so powerful abroad. But great social changes were gradually working themselves out, a revolution was taking place in the industrial world. The enlarged application of steam, the invention of machinery, improved methods of agriculture, the extended use of coal, the removal of the iron trade from the south to the north, and its great increase, were all tending to bring into greater prominence the trading, manufacturing, and artisan classes. The strange anomalies of the representation became still more glaring; change of occupation was not effected without much individual hardship, and the discontent arising from suffering was joined with that engendered by a sense of political exclusion. The ideas fostered by the French Revolution played their part in the general ferment. The determined and successful

effort of the Irish Catholics to obtain religious emancipation laid bare the increasing weakness of the governing classes. And at length the leaders of the Whig party made common cause with the classes hitherto excluded from government, and, backed at once by the traders and the artisans, forced upon an unwilling parliament the great Reform Bill of 1832. From that time till the close of the century there was a marked change both in the position of England and in the character of the questions which excited public interest. Still mistress of the sea, and possessed through its colonies of a world empire, England found enough to do in the preservation and improvement of this gigantic dominion, and as far as possible abstained from interference in continental quarrels. Once and again it showed its influence. In 1848, the year of revolutions, and in the subsequent consolidation of Italy, its sympathies were not hidden, but there was no thought of active interference. It allowed the great American republic to settle its disputes uninterrupted. It adopted the same attitude of non-intervention in the Prussian wars against Denmark, against Austria, and against France. It was only in questions which seemed to touch the safety of its Eastern empire that it drew the sword. The Crimean war was avowedly for the maintenance of Turkey as a check upon Russia, which was threatening the road to India. Of the same class were the wars in Egypt and Afghanistan. Still more directly when India itself burst into insurrection was England called upon to interfere and engage in the victorious but terrible campaigns which marked the suppression of the Mutiny. The other wars, and they were not few, were all connected with mercantile and colonial interests; the principal was the war with the Transvaal and Orange Free State in 1899-1900, ending in both these republics being annexed to the crown as British colonies. As to the questions which, after the passing of the first Reform Bill, excited public interest, the chief were the extension of the political franchise, the reform of municipalities, the repeal of the Corn Laws, the establishment of Free Trade, the improvement of the condition of the working-classes, the regulation of strikes and trade-unions, an equitable system of compensation for injuries, a national system of education, and the management of Ireland.

During the South African war of 1899-1900 a great impulse was given to the feeling of solidarity between the mother-country and her colonies; and in the first years of the 20th century, prior to the outbreak of the Great War, imperialistic ideas grew in strength, manifesting themselves mainly in agitation for imperial preference. In 1907 self-government was granted to the Transvaal and to the Orange River Colony, while in 1909 the union of South Africa was completed. In foreign affairs in this period the establishment of an alliance with Japan, and the negotiation of *ententes* with both France and Russia, marked a definite departure from traditional policy. At home the passing of the Parliament Act (1911), with its limitation of the veto of the Lords, was a constitutional change of first magnitude, while the carrying of a bill for the payment of members (1912) was an important measure of parliamentary reform. Educational reform had its legislation in an act of 1902, while in social reform the Old Age Pensions Act of 1908 and the National Health Insurance Act of 1912, together with the inauguration of campaigns for land reform, were the leading features. Throughout the period industrial unrest was rife, infused at many points by syndicalist doctrine from France. In 1914 Home Rule and Welsh Disestablishment acts were passed, but the same year brought the Great War (q.v.), and with it the suspension of the operation of these measures. At the conclusion of the Great

War the colonies of Germany passed in effect to England; but, at the same time, the war doctrine of self-determination was made the basis of agitation against English rule in Egypt and India. In the first instance, the protectorate established in 1914 was terminated in 1922, and the country recognised as an independent sovereign state; in the second, concessions were made in the Government of India Act (1920), but the demand for complete emancipation continued. In foreign relations the peace treaties which followed the war left England embroiled as perhaps not for a century in the affairs of Europe. At home the circumstances of the war accelerated reform of various kinds. Thus the Representation of the People Act (1918) granted votes to women, and in so doing anticipated later measures for the complete removal of sex disqualification, while it also otherwise extended the suffrage and effected a redistribution of seats; by an act of 1918 the cause of education was advanced in new directions; while in a measure of the following year schemes of housing reform were embodied. In post-war years the influence of revolutionary experiment abroad, the economic derangement of the peace, and the general disillusionment of the times accentuated the social unrest which had been growing throughout the century, and so produced circumstances in which the forces of labour added greatly to their electoral and parliamentary power. In 1920 the Welsh Disestablishment Act came into operation. To the Irish question, however, a fresh turn had been given by new doctrines of nationalism thrown up by the war, and the emergence of an Irish Free State came eventually to end the controversies of half a century. (See IRELAND.) The first Labour Government took office in 1924.

England, CHURCH OF. There is no trustworthy information as to the original preaching of the gospel in the British Isles; all that is forthcoming is either conjecture or legend. To the former category belongs the theory that St Paul was the first missionary thither—an opinion which rests only upon the apostle's own mention of his intended journey into Spain (Rom. xv. 24, 28) and the statement made by his convert and friend, Clement of Rome, that in his missionary travels he proceeded as far as 'the limit of the west' (*Epist. ad Corinth.* i. 5), words which have been construed as signifying Britain, because the farthest western boundary of the Roman empire. But that they do not in fact denote anything except the Spanish peninsula (much of which lies farther west than Britain) is made all but certain by the latter alone finding mention in the reference to St Paul in the Muratorian Canon, a document of the 2d century. To the class of mere legend belong no fewer than nine distinct accounts, specifying other apostles and saints as having evangelised Britain, one only of which—that which brings St Joseph of Arimathea to Glastonbury, and makes him shrine the Sangreal there—found popular acceptance. The most tenable theory which a consideration of all the factors of the problem suggests is that Britain was evangelised from Gaul, and that rather by sporadic and intermittent action than by means of an organised mission from Lyons or any other of the Gallic churches. Gildas, the earliest extant

British historian (circa 516-570), acknowledges that he has no information to give upon the subject, since all the documents which might have cleared the matter up had either been destroyed by the Saxon invaders, or carried out of the country by the exiles who fled before them. And this testimony serves as specific disproof of one of the legends—that which ascribes the conversion of Britain to missionaries sent by Pope Eleutherius (177-193), at the request of Lucius, king of Britain; for this story is based solely on an interpolation made in 530 into the record of the pontificate of Eleutherius in the *Catalogus Pontificum Romanorum*, a date too near that of Gildas's history for him to have been ignorant of the fact if then credibly attested. The story of the martyrdom of St Alban, said to be the protomartyr of Britain in the persecution under Diocletian, though incrustated with mythical details, may probably contain a germ of fact, as the scene of his death was a place of pilgrimage at the beginning of the 5th century; but the first tangible historical item in the annals of British Christianity is the record of the presence of three British bishops (Eborius of York, Restitutius of London, and Adelfius of Caerleon) at the Council of Arles in 314. Others attended the Council of Sardica in 347, and that of Ariminum in 360. And from this time forward we find definite allusions to a settled church in Britain made by writers such as St Chrysostom, St Jerome, and Sozomen.

At the beginning of the 5th century, Pelagius (Morgan?), a native of Britain, originated the heresy which bears his name, and it spread so rapidly in his own country that his opponents were obliged to invoke the assistance of the Gallican Church against it. Accordingly, Germanus, Bishop of Auxerre, and Lupus, Bishop of Troyes, were sent in 429 to combat the new heresy, and Germanus paid a second visit with the same object in 447.

This controversy exactly synchronises with the earliest Saxon invasions, which, though carried on unsystematically by detached bands of adventurers, met with no effective resistance, and gradually overthrew the Romano-British civilisation, forcing the native population steadily, if slowly, back into the western parts of the island, apparently extirpating the church and Christianity itself in the process of conquest. Thus England forms the sole exception to the rule visible in all other parts of the Roman empire, that the Teuton invaders submitted to the creed of the conquered, and adopted as much of their civilisation and polity as they were capable of assimilating.

But what the British Church failed to effect, perhaps even to attempt, was achieved by external agencies. Kent, the oldest kingdom of the Heptarchy or Octarchy, was also the earliest to receive the gospel; and Bede's picturesque narrative tells how Gregory, Archdeacon of Rome, was attracted by the appearance of some fair-haired Saxon slave-children exposed for sale in the forum, and on inquiry into their race and country was seized with a desire to become a missionary thither. He could not obtain the necessary sanction, because his services at home were too valuable to be dispensed with; but when he was elected pope he determined to take effectual steps for carrying out his original plan with other instruments. He chose Augustine, prior of St Andrew's monastery on the Coelian Hill, a foundation of his own, as head of the mission he projected, and sent him, accompanied by forty monks of the community, with supplies and with letters of recommendation to the bishops and sovereigns of Gaul. This policy directed the course which the mission was to take, for Charibert, king of Paris, had given his daughter

Bertha in marriage to Ethelbert, king of Kent, though a heathen, on condition that she should be permitted the free exercise of her religion, and be attended by a body of domestic chaplains. Ethelbert accepted the conditions, and repaired a ruined Christian church just outside Canterbury for their use, and was thus likely to receive Christian missionaries more readily than any other of the Anglo-Saxon kings. Moreover, he held the honorary precedence amongst them denoted by the title of Bretwalda, so that his example, if he could be induced to encourage the strangers, would be exceptionally influential throughout the country.

Augustine and his companions landed in Thanet on August 7, 596, and were granted an audience by the king in a few days under a great oak, to which they advanced in procession, preceded by a silver cross, bearing a picture of Christ, and singing the Litany. They were favourably received, and given permission to preach and make converts of such as chose to listen to them, while Ethelbert himself, about a year after the arrival of the mission, accepted their teaching, informed the Witan of his proposed change of religion, and obtained its sanction, besides inducing several of its members to follow his example, as did also great numbers of the commons. Hereupon Augustine, in compliance with directions given him by Pope Gregory before his departure from Rome, went to Gaul to obtain episcopal consecration as Archbishop of the English, which he obtained at the hands of Virgilius, Archbishop of Arles (November 16, 597). He sent news of his success to Rome, asking for additional men and supplies, which were promptly sent, together with the distinction of the archiepiscopal pall for Augustine himself, and a commission empowering him not only to erect twelve suffragan sees in southern England, but to do the same in the north, and appoint any one he pleased as metropolitan over them at York. But in fact little solid advance was made outside Kent for a considerable time, since a conference between Augustine and representatives of the British Church broke down through prejudice and misapprehension on both sides; and the apparent success which attended the missions in the kingdoms of Essex, Mercia, East Anglia, and Northumbria proved unsubstantial, for even those of them which had been most unanimous in accepting the gospel relapsed into heathenism after the death of the convert kings.

The recovery of these regions is due to the Celtic missionaries from their headquarters at Iona, an Irish colony, and notably to Aidan and his successor Finan. All northern and central England was evangelised by their agency, and also Essex, so that about two-thirds of the whole area of the country owes its Christianity to this source. The remainder is thus accounted for: East Anglia was converted by Felix, a priest from Burgundy, whom Augustine then raised to the episcopate; Wessex, by Birinus, an Italian, who obtained a mission from Pope Honorius, independently of St Augustine's, in 634; and Sussex, the last part of England to receive the gospel, by Wilfrid, Bishop of York, then exiled from his own diocese (681-685), the Isle of Wight being actually the latest scene of conversion. No difficulty was raised by the Scotch-Celtic missionaries in accepting the primacy of Canterbury, and, in fact the several missions were welded into a single church during the life of Theodore, seventh Archbishop of Canterbury, who sat from 668 to 693. He it was who at the Synod of Hertford in 673 broke up the existing dioceses, each of which was coterminous with one of the Saxon kingdoms, into sixteen more manageable

areas, all of them suffragan to Canterbury. In 735 York was made an archbishopric and metropole of the northern part of the island, though with precedence after Canterbury; but this distinction was not given formal expression until 1093, when the title 'Primate of All England' was attached to the holder of the latter see. The Welsh Church remained separate for a much longer time than that of Northumbria. It is not till 875 that there is proof of the intervention of Canterbury within its limits, for which the lack of any Welsh metropolitanate gave the occasion, and not till 1188 was the union with the Church of England fully effected.

Save for the sufferings inflicted during about a century by the piratical invasions of the pagan Danes, who treated the Saxon Christians much as the British Christians had been treated by the forefathers of those Saxons, the Anglo-Saxon Church remained peaceful and undisturbed till the Norman Conquest, living a life of its own, having scarcely any intercourse or relations with the continental churches, and ministered to by an episcopate and clergy with slender claims to learning, culture, or activity.

The Conquest, albeit attended with much hardship and oppression of the subjugated nation, and with some extrusion of Saxon prelates the moment William felt himself firm on his new throne, proved almost an unmixed benefit to the church of the country. The Norman clergy, while no less devout than the most pious Saxons, were far their superiors in learning and intellectual gifts, and the men whom William intruded into the places of the deprived Saxons, whether as bishops or abbots, were for the most part of high mark, in proof of which it will suffice to name Lanfranc, Archbishop of Canterbury, Osmund, Bishop of Sarum, and Anselm, Lanfranc's successor, though his accession to the primacy was under William II. in 1093. The great Norman nobles as a rule exercised their patronage with similar discernment; they founded abbeys and churches, cathedral and parochial, larger and statelier than had been known in England; they invited over monks from the most celebrated foreign monasteries to occupy the new foundations, and they brought the English Church, after several centuries of virtual isolation, again into touch with the rest of Latin Christendom. One factor in this last change, however, had results which no one could then forecast, for it was the Conqueror himself who availed himself of the opportunity given by the abortive Saxon revolt of 1069 to depose the Saxon primate Stigand. For this purpose he invoked the assistance of the pope, who sent two cardinals as legates. Under their presidency a synod was held at Winchester in 1070, wherein the deprivation of Stigand was effected, and the first precedent established for the internal jurisdiction of the papal authority in England. When William's own strong personality was removed, difficulties at once arose from this cause, as in the disputes concerning the investiture of bishops between William II. and Henry I. on the temporal side, and St Anselm upon the ecclesiastical part, which ended in a compromise whereby the king abandoned the claim to invest bishops by the delivery of the pastoral staff and the episcopal ring, and the church agreed not to treat the act of homage on the part of a bishop-elect as disqualifying him for consecration. This was a practical victory for the civil power, and the beginning of that mode of its nominating English bishops by uniting a letter-missive in favour of a specified person to the *congé d'élire*, or license for election, which still prevails.

Graver troubles arose when Henry II. endeavoured to abolish the privilege of clergy, which exempted

all members of the clerical body from the jurisdiction of the civil courts, even for the most serious offences against the laws. He availed himself of a vacancy in the see of Canterbury to nominate his chancellor, Thomas Becket, to the primacy, in the expectation that he would assist in bringing about this desired change. At first the new archbishop gave some support to the plan, but at the Council of Clarendon, where the new laws were synodically voted, he refused to validate the acts of the council by affixing his official seal to them, to the great anger of Henry, who was present, and who immediately took action which drove Becket into exile for six years. On his return to England, he excommunicated the Archbishop of York, the Bishop of London, and the Bishop of Salisbury for usurping his functions during his absence, and they at once proceeded to Normandy to complain of him to the king. The hasty words which the news drew from him were caught up by four knights of the court, who hurried over to England, and murdered the archbishop in his own cathedral. The crime proved fatal to the proposed measures, which Henry was compelled to abandon; and though some limitation of the privilege of clergy took place in the reign of Edward III., and again in that of Henry VII., it was not till the Reformation statutes of 1536 and 1541 that it was finally abolished.

The Papacy was even more successful in the reign of John than in that of his father. The pope then was Innocent III., one of the ablest and most ambitious of the Roman pontiffs, who set aside a disputed election to the see of Canterbury, and appointed Cardinal Stephen Langton instead of either claimant. The king refused to accept the nomination of Langton, and the pope at once put the kingdom under an interdict, which involved the cessation of the offices of religion throughout the country. But as John proceeded to retaliate by acts of violence against the clergy, a sentence of excommunication was fulminated against himself, quickly followed by one of deposition, whereby his subjects were released from their allegiance, and the kingdom was granted to Philip, king of France, who was enjoined to invade England with an army. Although John called out a military force to resist the threatened invasion, he was afraid to trust himself to his alienated subjects, and made secret terms with Pandulf, the papal legate at the French court, in accordance with which John signed a deed of resignation of his insular dominions into the hands of the pope, to be held from him as his feudal vassal on payment of a thousand marks yearly, and actually executed this undertaking in the church of the Templars at Ewell, near Dover, in 1213, kneeling before the seated legate, laying the crown at his feet, and taking the oath of homage to the pope as his lord paramount. The exiled prelates hereupon returned, and Cardinal Langton gave absolution to the king. But although Langton was thus forced upon the country by external influence, he at once identified himself with the popular party, headed the confederacy of the barons formed to extort reforms from John, disregarded the pope's attempt to protect his vassal, and compelled the signature of the Great Charter at Runnymede in 1215, refusing to publish the bull with which Innocent III. attempted to quash it. Nevertheless, the vassalage of the kingdom was not suffered to remain a mere dead letter of titular dependence on the Papacy; it continued as a very potent fact during the long reign of Henry III., when the church patronage was almost monopolised by the popes, in virtue of 'mandates' and 'provisions,' and exercised chiefly in favour of Italians; while the revenues drawn to Rome from England, as vouched

by a complaint lodged at the Council of Lyons in 1274, largely exceeded those of the crown. This policy, which at once affected the people generally in their religious relations throughout the parishes all over England, and the state in its corporate character, did much to beget a temper of revolt against the Roman claims, as those of an alien and even hostile power, and had much to do with the spread of Lollardism at a somewhat later period, and even with the permanent success of the Reformation.

There was, however, an event of a very different kind which also marked the 13th century: the introduction of the new institute of friars, then but lately founded by Francis of Assisi and Dominic Guzman on a basis differing in several important particulars from the older monasticism which had played so great a part in church history. The Dominicans, or Friars-preachers, reached England about 1219, the Franciscans about 1224, being soon followed by the Carmelites and Augustinians. For a time they worked as marked a revival as they had already brought about in religion on the Continent, and the Franciscans became in addition famous for their learning, not only furnishing the ablest teachers to the universities, but producing men of such exceptional eminence as Roger Bacon, Duns Scotus, and William of Ockham. For a time the influence of the friars was wholly healthful and stimulating, but the very popularity which they enjoyed crowded their ranks with unworthy members, and the greed which they soon evinced, as well as the anti-national attitude they assumed in consequence of their exemption from local jurisdiction, as holding directly from the pope, so that they viewed themselves as his liege-men and acted as papal garrisons in England, marred the fair promise of their advent, and made them additional factors in the growing alienation from Rome. This change of attitude towards the friars appears as early as the episcopate of Robert Grosseteste, Bishop of Lincoln (1235-53), who had been one of the first to welcome their arrival, but became their steady opponent towards the close of his life, as he also was of the papal usurpation of English church patronage.

Edward I. renounced that fealty to the Papacy which his father and grandfather had accepted, besides checking the transfer of land by the Statute of Mortmain in 1279; and his own grandson, Edward III., carried resistance much further—in 1350, by the Statute of Provisors, which put an end to the pope's encroachments on the rights of patrons; in 1353, by forbidding appeals to Rome under pain of outlawry; in 1367, by refusing to continue payment of the tribute with which John had saddled the kingdom; and in 1374-75, by an inquiry into the number and value of the benefices occupied by aliens, succeeded by an embassy to the pope to complain of the abuses. One member of that embassy, John Wyclif, Master of Balliol, Oxford, had a powerful, if temporary, influence in fostering opinions adverse to the current system, and the popularity of his translation of the Bible contributed much to the same end. His teaching, though officially condemned both by the university and the church, found many supporters both amongst the educated and the masses, and probably helped the enactment of the Statute of Premunire in 1393, as it certainly did the spread of Lollardism after his death in 1384. Active measures were taken for its repression under Richard II. and Henry IV., and the first execution by burning for heresy in England was that of William Sawtre, a London rector, in 1401. He was the earliest of many victims (including Sir John Oldcastle, Lord Cobham) during a persecution which lasted with little intermission till the

outbreak of the Wars of the Roses; but meantime the reaction against Rome was holding its course both in church and state, and was much increased by the high-handed action of Pope Martin V., who endeavoured to revive the abuses which successive kings and parliaments had abated or removed.

Some recovery of Roman influence, however, took place in the weak reign of Henry VI., and Cardinal Kemp, Archbishop of Canterbury, was not only nominated by the pope to the primacy, but avowedly governed the church as papal legate; a policy wherein he was followed by his successors Cardinals Bouchier and Morton, under the last of whom (1487-1501) the long struggle of the nation against papal encroachments seemed to end in final defeat, and in the reduction of England to a mere appanage of Rome. With the accession of William Warham, a patron of learning, to the primacy in 1502, some abatement of this subjection becomes visible; but the time for a far wider and deeper revolt was near at hand, seeing that the Lutheran movement, destined to influence the whole Western Church, took place during Warham's primacy, and rapidly affected even those who were most opposed to its principles. In particular, the widespread anger it aroused against practical abuses strengthened the hands of Cardinal Wolsey in undertaking the reform of the monastic houses in England, by purging the greater monasteries of their scandals, and suppressing small and useless foundations, drafting their inmates into the larger societies, and applying their revenues to educational purposes. But rougher hands were to carry on the work in a very different fashion from his temperate measures. The failure of Henry VIII. in obtaining a divorce at the pope's hands from his queen, Catharine of Aragon, since her nephew, the Emperor Charles V., was too powerful to be thus braved, led to his determination to break with Rome; and though Wolsey declined to assist his plans, and was disgraced in consequence, yet in Thomas Cranmer, whom, on Warham's death in 1532, he raised to the primacy, he found a ready instrument for his purpose. Cranmer declared the marriage with Catharine void, and the king's private marriage to Anne Boleyn valid; while Henry retorted upon the pope's verdict of 1534 against this union by hastening on the proceedings of the famous 'Reformation Parliament,' which continued from 1529 to 1536. Herein papal licenses and bulls were prohibited, the king's ecclesiastical supremacy declared the law of the land, and its impugnement punishable with death; the submission of the clergy, compelling them to accept a revision of the canons by a royal commission and to assemble in their convocations only when summoned by the king's writ, was extorted; the payment of annates to Rome was forbidden; and the statute in 'Restraint of Appeals,' terminating all ecclesiastical suits within the kingdom by prohibiting the carriage of any suit before the pope, was enacted.

These changes seem to have been received, not only without resistance, but with real ap royal, even by the clergy as a whole; and, except for the breach with Rome, little alteration was made in the ordinary routine of church teaching and discipline, though some slight advance was made in the reforming direction by the issue of the Ten Articles in 1536 and the *Institution of a Christian Man*, or *The Bishops' Book*, in 1537, recast and re-issued in 1542 as the *Necessary Erudition of a Christian Man*, or *The King's Book*. A greater practical change was carried out by the wholesale spoliation and suppression of the monasteries, mainly by the agency of Thomas Cromwell between 1536 and 1539, and the devolution of their great revenues, including the impropriated tithes of

parish churches, into the hands of the king and the secular landlords. The Act of the Six Articles in 1539 was aimed at the more advanced Reformers, and made several of their favourite tenets heresy at statute law, so that it was no longer possible for the accused to save his life by abjuration, as it had been under the previous system. Some modification of its severity was made in 1543 and in 1544, and the beginnings of vernacular services appear in the publication of the Litany in English. In addition to an earlier permission for the private use of the Psalter, Creed, Lord's Prayer, and Hail Mary. Such was the posture of affairs at the death of Henry VIII. in 1547.

Under the child-king Edward VI., the reforming movement was pushed on much more rapidly, and is sharply divisible into two distinct periods: an earlier one, whose landmarks are the Order of Communion of 1548, and the First Book of Common Prayer in 1549, both of them the work of the native clergy, and drafted on mainly conservative lines; and a later one, when the influence of the foreign Reformers domiciled in England, and notably Bucer and Peter Martyr, became dominant with the king's advisers, and resulted in the destruction of the altars of the churches in 1550, the issue of the Second Prayer-book in 1552, by royal and parliamentary authority only, and without the assent of the church, and the compilation of the Forty-two Articles, the first draft of the present Thirty-nine, in 1553. So much wanton havoc had been wrought under colour of reformation in the closing years of Edward's short reign that Mary's accession was received without alarm, and even with welcome, and that by the clergy no less than by the laity, with the exception of those who felt themselves imperilled. But though she immediately set herself to undo all the work of the preceding quarter of a century, aided by her husband Philip II. and her kinsman Cardinal Pole, so that she was enabled with the assent of parliament to bring the church and nation back into the relations with the see of Rome which had prevailed up to 1529, yet her impolitic cruelties and the fierce persecution of which Cranmer, Ridley, Latimer, and Hooper were the most conspicuous victims, alienated the national sympathies from her, and led to a fresh reaction, which at once took shape under her successor Elizabeth. In 1559 the Act of Uniformity re-establishing the Common Prayer-book, and also a statute reviving the royal supremacy, were enacted; the Thirty-nine Articles were published in 1563, and the Church of England placed in a position midway between the attitudes in the two periods of Edward VI.'s reign already referred to. The Marian bishops, who refused to accept the changes, were deprived, but not otherwise harshly treated, and only 189 of the whole clerical body, inclusive of these fourteen prelates and six abbots, out of a total of 9400, declined to conform; while there was no separatist Roman Catholic body in England till after Pius V. issued his Bull of Excommunication against Elizabeth in 1570, nor were they organised in anywise till 1598. See ARCHPRIEST.

The Puritan section in the country, however, was far from content with the amount of reform achieved, and quickly came into collision with the authorities in church and state, mainly upon minor details of ceremonial. The first secession on these grounds took place in 1563, and was generally condemned by the leading foreign Reformers; but nevertheless Puritan principles spread very fast, and became powerful in parliament, though not sufficiently so to prevent the enactment of a severely repressive statute in 1593, when the Puritans' own violence and intractability had provoked a reaction against them, and they remained quiescent during the remainder of Elizabeth's reign. They revived in

activity under James I., and had high hopes of success; but the Hampton Court Conference, wherein an attempt was made to arrive at an amicable understanding between them and the church, proved abortive; and while their disciplinary proposals were checkmated by the Canons of 1604, their doctrinal aspirations were even more effectually and permanently defeated by the rise of the Anglo-Catholic school of theology, which exchanged the destructive and innovating temper which had inevitably prevailed during the crisis of the Reformation, when the removal of abuses was the main object, for a constructive and conservative one, making constant appeal to the standards of the ancient undivided church, and being especially opposed to the tenets of Calvinism and Zwinglianism. But the king's feebleness of nature made him ill able to guide the country at such a time, and his political blunders brought about an alliance between the Puritans and the patriot party, who were aggrieved by many acts of misgovernment. The authorities of the Church of England, contrariwise, both under James and his successor Charles I., lent themselves to the support of absolutist views, and thus incurred much odium, which was considerably increased by the dissatisfaction aroused by the action of Archbishop Laud, whose good intentions were not accompanied with practical discretion, but were marked with much high-handed intolerance. The reaction was swift and violent: the Westminster Assembly of Divines met in 1643, and adopted from Scotland the Solemn League and Covenant, one detail of which is the total abolition of prelacy, and which parliament made binding on all persons in England over the age of eighteen; in 1645 the Book of Common Prayer was forbidden under severe penalties, and the Directory of Public Worship substituted for it; in the same year Archbishop Laud was brought to the block, and the Church of England, as a body holding a recognised national position and free to exercise its functions, disappeared from view for the fifteen following years. The restoration of Charles II. in 1660 was attended by the return of the exiled clergy and the reinstatement of the church, while the Savoy Conference in 1661 decided the issue as to the general aspect of the revived communion in favour of the High Church or Anglo-Catholic view, by revising the Prayer-book in its present form, which was enforced by an Act of Uniformity in 1662, a measure followed by the resignation of a number of the ministers admitted to benefices under the Commonwealth, estimated variously at from 800 to 2000. This was virtually the last settlement of ecclesiastical affairs in England by the joint action of church and state, and the many events which have since occurred to condition them have not materially altered its broad features. The illegal exercise by James II. of a dispensing power in issuing the 'Declaration of Indulgence,' which, though ostensibly meant for the relief of all Nonconformists, was designed to cover the legalisation of Roman Catholicism, and the trial of the seven bishops who refused to give it circulation in their dioceses, directly caused James's deposition, and resulted hurtfully in some respects for the church.

For the Nonjuring schism under William III. deprived the church of many pious and some able men whom it could ill spare, and contributed something to the gradual cooling of zeal and the laxity of doctrine which marked the Hanoverian period and were furthered by the influence of such prelates as Hoadly and White Kennett. But socially the Church of England touched its highest point of influence just before the season of decay. At the close of Queen Anne's reign it appeared to be strong and successful everywhere, and there was

practically no competitor in the field, as both Roman Catholics and Nonconformists were few and powerless. But with the silencing of Convocation under George I. in 1717 (made feasible by its impolitic surrender in 1664 of the right of the clergy to vote all taxes payable by them), and the steady encouragement given to the ultra-Broad Church section of the clergy, a blight came upon the church, and it rather vegetated than actively lived thenceforward till nearly the close of the 18th century; for the Methodist movement, begun by John and Charles Wesley in 1727 on the footing of a guild within the church, and given formal shape in 1740, began to assume the status of an external sect in 1760, and soon afterwards became the active rival of the church. The Evangelical revival towards the close of the century owed much of its success to the alarm caused by the French Revolution, since the adoption of freethinking opinions in England was thought likely to lead to results similar to those of the Terror; but though it did much for individual piety, the notion of working in and for the church at large, or as a national institution, does not seem to have so much as crossed the minds of its leaders, and it did thus nothing whatever to promote any corporate reforms, though achieving much in raising the standard of clerical devoutness.

It was reserved for the factor variously known as the Oxford or Tractarian movement, or by its advocates as the 'Catholic Revival,' to make this omission good, and to stimulate the energies of the whole Anglican communion. The movement itself was immediately occasioned by a statute enacted in 1833 suppressing ten bishoprics in the Church of Ireland, which at once prompted the question, 'If the like policy should at any time prevail in England also, and lead to the overthrow of the church as an establishment, what would it have to fall back upon for its very existence as a corporate body?' The answer to this question was given in the 'Tracts for the Times,' issued from Oxford at intervals during 1833-41, and chiefly written by Newman, Keble, Pusey, Isaac Williams, and Richard Hurrell Froude. They at once excited active controversy, seeing that they not only traversed the Low and Broad Church positions, but also that of the contemporary High Church school itself, which was content to acquiesce in a theology bearing clear marks of 18th-century influence, and differing materially from that of the great Stuart divines, which the Tract-writers aimed at reviving. Although at first the line adopted by the school as a whole may be roughly described as a *via media* between Roman Catholicism and Reformation doctrines, although at first the former system was freely criticised, yet two great waves of secession to the Roman Church, in 1845 and 1850, the earlier occasioned by the condemnation of Tract XC., written by Dr Newman, and the latter by the Gorham Judgment, drew considerable numbers of its more distinguished members with them, and not only weakened it seriously at the time, but seemed to justify all the adverse criticism it had met, and to discredit it altogether. Yet it stood the shock firmly, and proceeded on the lines originally sketched out, and that with such energy and success as entirely to change the face of the Anglican Church in the succeeding half-century and beyond. The great development of church building and restoration, the revivals of convocation and of sisterhood life, the creation of a copious and learned ecclesiastical literature, the impetus given to the foundation of colonial and missionary dioceses and to the increase of the home sees, at first merely suffragan, but later as separate dioceses, the introduction of a higher standard of clerical life and work, and the embellishment of

public worship, are the chief results of its labours; and what might have been less anticipated from its origin, it has shown itself not less ready in adapting agencies of nonconformist birth and usage to the purposes of the church. That it has in fact been the determining factor in these respects, and has rather drawn the remaining schools into the current than been anticipated or aided by them, is vouched by the date, not less than by the character, of the reforms, since they do not begin to be manifest, even in germ, till the Oxford movement became powerful, and was translated from theory into practice. As regards the alleged tendency towards Roman Catholicism, that must be judged not by the degree in which the school is in sympathy with Roman Catholics rather than with Protestants on certain issues, nor yet by counting up individual secessions in that direction, but by the broader inquiry into the growth of the Roman Church in England since the Oxford movement has affected the condition of religion in the country. And the fact is, as attested alike by the marriage returns (especially trustworthy in the case of Roman Catholics, because of their strict discipline in this matter) and by the calculations made by the Roman Catholic authorities themselves, they do not increase at the same rate as the nation at large, and constitute, despite their threefold sources of increase—births, immigrants, and conversions—a slowly but steadily diminishing factor in its ratio to the population, and chiefly dependent, even so, upon the Irish element to maintain its numbers.

In marked contrast with the torpor of the 18th century and the earlier years of the 19th, the history of the Church of England has in recent times been as crowded with events profoundly affecting it as any corresponding period of time during the Reformation era; with this notable difference, the absence of the Erastian character which the direct intervention of the crown and the civil power in general gave then to the aspect of ecclesiastical affairs. In the modern revival of the Church of England the court has had neither share nor sympathy; there has been rather more opposition than aid from parliament, owing to the temper of the large nonconformist element in the House of Commons; and the legal tribunals have been actively hostile; but no serious check or delay has been interposed to the movement by any or all of these adverse influences. It is possible to name only the most salient events of the period in the briefest fashion to complete this historical outline. The beginning of Queen Victoria's reign was marked by the enactment of the Pluralities and Non-residence Act in 1838, and of the Church Discipline Act in 1840. The development of the colonial episcopate (which, though initiated in 1787, had increased to no more than five sees down to 1836) began in 1841, and was steadily rapid in operation. The Gorham case, decided against the ruling of the Court of Arches by the Judicial Committee of Privy-council, synchronised with the establishment of a Roman Catholic hierarchy in England by Pius IX. in 1850, professedly as a restoration of the pre-Reformation episcopate. Convocation was revived in 1853, through the action of Lord Aberdeen, then premier, and has met regularly ever since. In 1860 *Essays and Reviews* was published, and was soon followed by kindred but bolder writings of Dr Colenso, Bishop of Natal; and though both the *Essays* and the bishop were condemned by the ecclesiastical authorities, these sentences were reversed, the former in 1864, the latter in 1865, by the Judicial Committee; against which findings strong protests were made (in the case of *Essays and Reviews* by 11,000 clergymen), and the Convocation of Canterbury affirmed synodically the contrary condemnations. The Church

Congresses, which have done so much to make the outer public familiar with the working of the English Church, began in 1861; the Pan-Anglican Conferences, equally powerful in welding together the separated parts of the vast Anglican communion, in 1867. Contrasting with the license allowed to the Low and Broad Church schools by the Privy-council decisions, the judgment in the suit of Liddell v. Westerton (1857), was largely, and those in the suits of Martin v. Mackonochie (1869), Hebbert v. Purchas (1871), and Clifton v. Ridsdale (1877), were entirely, hostile to the High Church liturgists, condemning various ceremonial adjuncts of public worship which they held to be permitted or enjoined by the formularies. But these findings have been so riddled with destructive criticism by eminent jurists and other experts as miscarriages of justice that they have never commanded respect or obedience. The restoration of the long dormant class of suffragan bishops took place in 1870, and they now form a considerable factor in the home episcopate; while the increase in the number of English dioceses, originating with the foundation of the sees of Manchester and Ripon in 1836, was followed by the re-erection of the sees of Bristol and Coventry, and the erection of Liverpool, Newcastle, St Albans, Southwell, Truro, Wakefield, Birmingham, Southwark, St Edmundsbury and Ipswich, Chelmsford, Sheffield, Bradford, &c. In 1920 the first meeting took place of the National Assembly of the Church of England. This body, a creation of the Enabling Act, or properly the Church of England Assembly (Powers) Act, 1919, was the outcome of a claim by the Church for lessened state control and for greater powers of self-government. The Assembly, a representative body consisting of a House of Bishops, a House of Clergy, and a House of Laity, has power to legislate regarding church affairs, but no measure passed by it becomes law till, following the approval of an ecclesiastical committee established by the act, and consisting of fifteen members of the House of Lords and fifteen members of the House of Commons, each House of Parliament has passed a resolution to that effect.

The polity of the Church of England is episcopal, and the area is territorially distributed into two provinces, Canterbury and York, each presided over by an archbishop. The Church of England claims that its bishops are the legitimate and canonical successors of the pre-Reformation hierarchy, and has carefully fenced the episcopal office with safeguards to insure its regular continuance. But Roman Catholic controversialists allege that there was a complete solution of continuity at the accession of Elizabeth, when Matthew Parker was appointed Archbishop of Canterbury in the room of the recently deceased Cardinal Pole. Yet not only has the regularity of the English succession been acknowledged by such eminent authorities as Bossuet in earlier and Dollinger in more recent times, but there is decisive proof that the objections now alleged are merely factitious afterthoughts. The question of the necessity of papal confirmation to validate the status of bishops was debated in the Council of Trent, 30th November 1562, and objections were adduced against its obligation. But it was argued on the other side that to rule against it would be dangerous, because the only argument admissible against the orders of the English bishops was that they had not papal confirmation, since they proved that they had due call, election, mission, and consecration; and the whole council accepted this view of the situation (Le Plat, *Monum. Conc. Trident.* cclxxi.).

The doctrinal standards of the Church of England are primarily the Book of Common Prayer, including the three Creeds occurring therein; and

secondly, the Thirty-nine Articles. The first four general councils are also part of her legal system, and there is a general appeal to Holy Scripture as interpreted by 'the Catholic Fathers and ancient bishops. She differs from the Roman Catholic Church by the rejection of the distinctively Roman tenets embodied in the modern articles of the Creed of Pope Pius IV., and from the Eastern Church in a less degree, and chiefly in respect of the invocation of saints and the cultus of images, as not warranted either by Scripture or by the church of the first five centuries. On the other hand, she differs from the societies which have sprung up since the Reformation by requiring episcopal ordination for all her clerical members; by the structure and tone of her Liturgy, which is simply a translated and abridged revision of the pre-Reformation Missal, Breviary, and other office-books; and by her refusal to admit into her formularies any tenets which have not the warrant of antiquity, whatever plausible arguments may be adduced for them from the letter of Scripture. She has always exercised strong attraction upon the educated classes, and has probably a larger proportion of cultured laymen actively interested in and working for her than any other communion of the day, and in England she has also retained the agricultural class. The lower middle class and the town artisans constitute the strength of English Nonconformity, though the revival born of the Oxford movement told strongly upon this class also. The advance of the daughter-churches in the United States and the Dominions has been very great.

English Language. GENERAL INTRODUCTORY SKETCH.—The development of the English language can be traced in a series of written documents extending back to the beginning of the 8th century. It is convenient and necessary to distinguish several well-marked periods or stages of development during this long space of time, and it is usual to divide the life-history of English into three main periods, respectively designated Old English (also called Anglo-Saxon), Middle English, and Modern English. These divisions are often further subdivided into Early and Late Old English, First Transition English, Early Middle English, Late Middle English, Second Transition, Early Modern, and so on. The approximate dates generally assigned to the various main periods are: Old English, down to 1050; Transition, from 1050 to 1150; Early Middle English, from 1150 to 1250 or 1300; Late Middle English, from 1300 to 1400. After this date (that of Chaucer's death) some scholars, including the present writer, would place Early Modern, while others prefer to regard the 15th century as Second Transition, making Early Modern begin about 1500.

It is very doubtful whether this minute division is desirable; indeed, it is more important to have a sense of continuity, and to realise that the process

of change and development is continuous, and that every age is, in fact, one of transition. Just as the generations of men pass one into the other, and overlap, so does the language which they speak pass, by imperceptible stages, from what we call Old English into Middle English, and thence into Early Modern, and so on. It appears that many sound changes, which all agree are characteristic of the Modern period, were at least well begun by the first quarter of the 15th century (see *English Sounds*). This is proved by the spellings and rhymes found in documents written at that time. If this is so, we must suppose that the 'new' pronunciation was probably in existence, in some districts at least, already before the end of the 14th century. If that was so, then Chaucer, whom every one agrees to consider a Middle English writer, must have heard the beginnings of Modern English; indeed, he may himself have shared some of its characteristics. In spite of this unbroken continuity, however, this absence of leaps and bounds in development, and of clear-cut periods in the history of English, we can undoubtedly trace well-defined characteristics which distinguish the language of one age from that of another. These differences involve the language as a whole, not only those features which can be analysed and easily described, such as changes in pronunciation, in vocabulary, in accidence, and in syntax, but those subtler shades which defy analysis and can only be grasped by means of long and sympathetic study of the sources, namely, the spirit and atmosphere of the style, what is rather vaguely called the *genius of the language*, which naturally changes with the general ideas and state of culture prevalent in a given age. It is not merely the linguistic means whereby men express themselves—the external and audible part of language—which is modified from age to age, but that which is expressed—that is, the outlook on life, the wishes, hopes, and fears, the characteristic kind of spirit and consciousness of each generation. The student who patiently makes himself acquainted with the variegated and ever-changing drama of English speech throughout several centuries is, indeed, sensible of this unfolding of the human spirit made manifest in verbal expression, but he finds it difficult to delimit the beginning and end of the several phases with rigid chronological exactitude. The most striking general fact in the history of English is the emergence, during the 15th century, of one from among the many dialectal types, as the chief vehicle of literary expression, a form of speech which in course of time attains so great a prestige and dominance that before the end of the 15th century it has become practically the sole written type—though still slightly modified by local influence in districts remote from the metropolis—which is used to the exclusion of others, not only in works of real literature, but in official documents of all sorts, and even in private letters. Of these latter large numbers are preserved, written in English during the 15th century, by persons of nearly all classes, from kings and queens, bishops and great noblemen, from country gentlemen and merchants, from officials, and the humbler sorts of domestic servants. This common dialect was, as we shall see, originally that of London and its neighbourhood; it was the dialect in which Chaucer wrote, which Caxton and the other early printers used, to the best of their ability, and it was destined to become the language of literature, and gradually, and much later, the dialect which all educated people, no matter from what part of the country they came, found it convenient to speak. This is the dialect which every one means at the present time when he speaks of *English*, and it is the history of this dialect

with which all 'histories' of English are mainly concerned.

But the emergence of standard and literary English, its adoption as the only written form, was a slow process, and the spread of a spoken standard was slower still, and we are bound to take a general survey, however slight, of English as a whole, so far as the sources at our disposal permit, down to the end of the 14th century. Soon after that date we can confine our narrative to the fate, throughout the succeeding centuries, of the one main type.

On its first introduction into these islands English was a very pure representative of the West Germanic group of languages of which it was a member, and it bears a particularly close resemblance to Old Frisian and Old Saxon. The vocabulary of Old English was at first very pure West Germanic. It contained certain elements borrowed from Latin; some, which for the most part are found in the vocabularies of other West Germanic tongues, incorporated already in the continental period, others acquired from speakers of Latin in Britain, and yet a later group of words derived through the influence of the Roman Church after the conversion of the English to Christianity. Later on Scandinavian words pass into the language. The inflexional system of Old English was typically West Germanic. We find the whole group of verbs known as 'strong' verbs which express the past tense and past participle by an alteration of the 'root' vowel—*rīsan—rās—risen*, &c., which survives in *rise—rose—risen*; the 'weak' verbs, which form their past and past participle with the suffixes, *-ode, -ed, -ode, -od*; the case endings of nouns and adjectives, though somewhat dilapidated compared with those of Gothic, and the distinction between strong and weak declensions in these two categories are common to all Germanic languages; the pronouns, prepositions, and numerals, the word order and general principles of syntax are essentially Germanic in character.

The most characteristic feature of Old English, if we compare it with the other languages of the West Germanic group, is the changes which have occurred in the vowel sounds. These are far-reaching and very remarkable. Some of them must have taken place already in the continental period, others, and by far the larger portion, seem to have developed on British soil (see section *English Sounds*). The effects of these changes, while perhaps hardly sufficient in the oldest period to make English unintelligible to the speakers of such closely related languages as Old Saxon and Old Frisian, were nevertheless the starting-point whence the external form of our language has gone on diverging from Continental Germanic speech, so that the identity of words in English and the dialects of Low German has long been generally unrecognisable without special study.

But English, even in the oldest period, was not quite undifferentiated. The various tribes—Angles, Saxons, and Jutes—had, as we must suppose, severally, from the beginning, certain slight differences in their mode of speech (see *English Dialects*).

When all is said and done, the differences, mainly phonological, between the various dialects in the O.E. period, so far as these can be distinguished in the written records, are comparatively trifling, and apparently could have offered no obstacle to social intercourse between speakers of the different types.

Under King Alfred, Wessex obtained a dominant position among the English kingdoms and provinces; her kings were kings of all England, and the West Saxon dialect became the current and standard form in official and literary documents.

Hence nearly all records in English, written after King Alfred's time down to the Conquest, are either in pure W. Saxon, or in a form in which W. Saxon is the principal element and basis. The deviations from this type are very few, so that our knowledge of the precise character of the other dialects is comparatively imperfect. This dominance of W. Saxon as the common literary dialect was not destined long to survive the Norman Conquest.

By the side of the ordinary dialect of prose, there existed, in the old period, a poetical language, differentiated from the former, more by certain archaisms and tricks of diction than by actual differences of dialect. Practically all the metrical compositions in O.E. have come down to us in what is virtually fairly pure and characteristic W. Saxon, with a mixture of certain occasional forms which are apparently chiefly Mercian in character. Whether this is due to the existence of a traditional poetic dialect in which these different elements were conventionally blended, or whether it should be ascribed to the lapses of copyists, is not yet satisfactorily settled.

The most characteristic feature of O.E. poetical diction is its extreme use of metaphorical expressions for common things. Thus a king or prince is the 'protector of heroes, or warriors,' the 'ring,' or 'treasure giver'; a sword is a 'battle friend,' a 'war,' or 'battle ray,' a 'sharp edge,' &c.; a ship is a 'sea stallion,' a 'sea mare,' a 'bird,' a 'sea-bird,' &c.; the sea is the 'whale's country,' 'whale's bath,' the 'path of the whale,' the 'bath of the gannet,' and so on. The ordinary prose style of the O.E. period, while rather awkward at times, especially in the 9th century, when King Alfred himself, though often eloquent, frequently gives the impression of not being a perfect master of his instrument, in the later portions of the period reaches a remarkable degree of polish, and is capable of great clarity and point, as well as of ease of movement, and a simplicity combined with loftiness of expression. The prose of Ælfric's *Homilies* exhibits these qualities to the greatest perfection. After the Conquest the amount of English prose composition is naturally very much reduced, and the tradition is gradually lost. Seventy or eighty years after the Conquest we have a very remarkable record of English speech, as well as an interesting picture of life and feeling, in the latter portions of the Peterborough Chronicle, which begins about 1137 and ends in 1154. Here we find a great simplification of inflexions, a spelling which indicates here and there that certain most important sound changes have occurred, a not inconsiderable number of Norman-French words, and a general structure and style of sentences which appear strikingly modern compared with the latest pre-Conquest writing.

It is evident, however, that these changes, apart from those in the vocabulary, are not the suddenly-wrought effects of the Conquest, but merely the first expression in writing of what had long been coming about in actual speech. From a careful examination of the phenomena which occur sporadically in documents written during the century preceding the Norman invasion, we gain the impression that the old order was passing away. The writers are anxious to adhere to the traditional literary models, but they betray here and there the fact that many changes in pronunciation have already taken place (see *English Sounds*).

This is what we should expect, but it is important to realise that the Conquest did not of itself produce the great changes in the inflexions, pronunciation, and general structure of the language which are sometimes attributed to it, and that the characteristic modifications which we think of as

characteristic of the M.E. period had begun long before the Conquest, and would have led to the same results if that great historical event had never happened.

It is noteworthy of English documents after the 12th century that they reveal a far greater degree of dialectal differentiation than is found in those of the O.E. period. This does not correspond to a new process of dialect creation, but is simply due to the fact that no single dialect type is any longer dominant, as was W. Saxon before the Conquest. The richly differentiated English speech now finds expression in all its variegated regional forms in the written documents. Another rather remarkable fact concerning the English of the 12th and 13th centuries is that in the documents of that period, especially in those written in the eastern areas covered by the old Danelagh, Scandinavian words in considerable numbers make their appearance for the first time. The number of these even in the latest O.E. writings is very small, though it is certain that they must have been current in many local dialects, and equally so that after the last of the Danish kings, no fresh Scandinavian influence was exerted upon English speech. Words and expressions of this origin must therefore have existed in the spoken language before the Conquest, although they do not find their way into literature.

Of all the various M.E. dialect types, the most important for the student of the history of the language is that of the S.E. Midland and S. Eastern areas, since it is the speech of a portion of that area which subsequently became the prevailing type, as has been said, in literature and in spoken English. Although the narrower area of London, the actual home of court speech, is but poorly represented by written records before the time of Chaucer, we possess a large number of writings representing the dialects of the S.E. and S.E. Midlands written before the end of the 13th century.

The dialects of M.E. are doubtless capable of being more exactly and minutely classified than has been done up to the present, and the precise distribution of the various characteristic features, in respect both of phonology and accidence, might, even with the material at present available, be ascertained with much greater certainty. Much remains to be done in these directions, but we are in a position to state that there are no clear-cut divisions between the different dialect areas. These pass by gradual and almost imperceptible stages one into another. Thus the dialect of Suffolk, which is S.E. Midland, has much in common with that of North Essex, which may be regarded as intermediate between S.E. Midland and the S. Eastern of the southerly areas of this county and of Kent, which latter is regarded as typically South-Eastern. Again, the dialect of E. Surrey has much in common with Kentish, but in the westerly area, near the Hants border, shows important affinities with the S. Western type of English.

In the west also there is no hard and fast line between Midland and Southern. The speech of Worcestershire, Oxfordshire, and South Shropshire, which is to be regarded as S.W. Midland, had many Southern characteristics. Passing northwards, the Midland dialects, both east and west, become more and more northern in type, until we get into areas where the full Northern type obtains.

The dialect of London can be traced in a rather unsatisfactory series of documents from the Conqueror's English Charter (1066) down to the poems of Davy (c. 1327), and thereafter much more fully in the works of Chaucer, and in official records. From a chronological survey it appears that while even the earliest London documents show a dialect

of rather a mixed type—that is, with a large proportion of the Saxon elements of Middlesex, alongside of traces of a more easterly type of Essex character—in the course of time the influence of a more Midland type gains ground, until in Chaucer's time the speech of the metropolis seems to have been very largely S.E. Midland in character. The Midland element is even more predominant after the close of the 14th century. This blending of dialect types was a perfectly natural process, and resulted from the peculiar geographical position of London and the tendency of the great city to draw ever-widening areas into its social and political orbit.

The influence of Norman-French upon the English vocabulary, which began to some extent under Edward the Confessor (d. 1066), who had a Norman mother, and had Norman officials about his court, increased after the Conquest, until it reached its culminating point in the 14th century. By that time not only was French the official speech, and that of the governing classes generally, but even humbler persons who had nothing to do with the court, and who were probably of pure English blood, often abandoned the use of English and spoke French, apparently from a kind of snobbery, as we learn from Trevisa's account (1385) of the languages of Britain. This state of bi-lingualism resulted in that intimate blending of the vocabularies of French and English which is so characteristic of our language. In 1362, however, English was introduced into the law courts, and in 1385 English was substituted for French in grammar schools, and even gentlemen, we are told, were giving up having the latter taught to their children.

It cannot be said that the dialect of London had become anything like the universal literary medium by the end of the 14th century. It was, however, tending that way, and it is worthy of note that John Gower (c. 1325–1408), although a Kentishman, used, in his lengthy poem *Confessio Amantis*, a type of English which, while containing a certain number of typical Kenticisms, is on the whole but little removed from the court English of Chaucer, and very different indeed from the broad Kentish of the *Ayenbite*, written about 1340. John Wycliffe also, a native of Yorkshire (d. 1384), left large numbers of tracts and sermons written approximately in the dialect of London, with, it is true, certain occasional Northernisms, and tinged also with more westerly features, derived presumably from his residence in Oxford.

During the 14th century the writers, or at any rate the scribes, adhere for the most part to a conventional and more or less rigid system of spelling which, while it expresses differences of dialect—e.g. E. Midland *lerning* compared with Western *turning*, &c.—tells us next to nothing of the actual sound changes which the course of time was bringing about in the several dialects. Thus from the MSS. of Chaucer, for instance, we cannot discover that the vowel sounds have undergone any remarkable change in pronunciation since the Conquest, although it is certain that pronunciation did not remain fixed for 300 years. There is, however, good reason for believing that during this period pronunciation had also altered considerably, and that the long vowels especially were gradually moving towards their present sounds. (See *English Sounds*.)

In the following century, however, the art of writing was extended far beyond the circle of the professional scribes, and many of the writers, while observing generally the rules of spelling which they had been taught, make numerous occasional lapses in the direction of unconscious phonetic spelling. The result of a careful study of these 'mistakes' is that a pronunciation very different from that

usually assumed for M.E. is shown to have existed before the middle of the 15th century, and it further becomes very doubtful whether we are justified in believing, as all scholars did until quite recently, that the so-called 'Continental' values of the vowels had survived practically unmodified as late as the end of the 14th century itself.

If we compare the spelling of many of the writers of the *Paston Letters* (1422-1509), that of the *Chronicle* of William Gregory (d. 1467), or of the *Cely Papers* (1473-88), with that of Chaucer, we might suppose that a very remarkable and rapid change in the character of the language had taken place since the beginning of the century. On the other hand, the spelling of Caxton (d. 1491) is to all intents and purposes still that of Chaucer, and reveals practically nothing concerning the changes which are established by the evidence of the less 'carefully' written private documents written earlier in the century. Caxton and the other early printers simply followed the habits of the professional scribes of the late 14th century, and thereby fixed permanently the main features of traditional English orthography, in a form which was no longer a mirror of pronunciation even in Chaucer's day.

An important event in the linguistic history of the 15th century is the dying out of Regional Dialect in written English, and the increasing currency of the London type, not only in literary works, but even in private letters, and that before the establishment of printing in this country (1476). (See *English Dialects*.) There are some traces of this process before the end of the 14th century. We find Sir John Fortescue in his *Governance of England* (1471-76) writing not in his native dialect of Devonshire, but in English as free from Regional influence as that of Caxton. John Shillingford, another Devonian, mayor of Exeter 1447-50, writes excellent London English in his private letters, with very few lapses into Westernisms. The city and guild records of such places as Exeter, Worcester, and Coventry, even those which are prior to Caxton, show but small traces of provincialisms.

With the appearance of printed books, which as Caxton himself tells us he produced in the speech of London, the knowledge of this form of English was rapidly extended, and the death-blow was given to Regional Dialect in literature. By the end of the century it may be said that, except in the North, and in Scotland, London English had become the universally employed form in writings of all kinds, published and private.

The general substitution of London English for the innumerable Regional types as a spoken language was a much slower process, and is not complete, in spite of the efforts of the schools, in the present day.

There are certain indications that towards the end of the 15th century the existence of an upper-class dialect as distinct from the speech of the humbler sort of people, in London itself, was recognised, but it is impossible to say for certain that this was so. It is not to be doubted, however, that such a differentiation, owing to social factors, had actually occurred.

It is certain that two types of London English can be distinguished in the writings of this time—one more definitely Midland in character, and the other containing more Southern features. It seems probable that the latter type was that of the court. In the following century the *Diary of Henry Machyn* (1550-53), a London tradesman, is a valuable record of middle-class English, and in its forms and general style offers a marked contrast to the speech of the more courtly and scholarly writers of the period. In Puttenham's *Arte of English Poesie* (1586), p. 157, there is a definite reference to the

speech of 'the inferiour sort' as distinct from that of 'men civil and graciously behauoured and bled'. The history of spoken standard English during the last three centuries shows very little influence from Regional Dialect, but that exerted by various Class Dialects, or forms of standard English differentiated by the force of social factors, has been very considerable. It is convenient to distinguish between *Received Standard*, or upper-class English, and *Modified Standard*, or those varieties which have grown up among the other sections of society which do not speak a Regional Dialect.

The influence of the different forms of *Modified Standard* has resulted in the substitution of other types of pronunciation from those formerly prevalent in *Received Standard*, sometimes in whole groups of words, sometimes in isolated words, in certain grammatical forms being discarded, and others adopted, and, in general, in a gradual shifting, from age to age, of the standard or 'correctness' in English speech.

It is plain, from the study of spoken English from the 15th century to the middle of the 18th, in the various sources of knowledge available, that the *Received Standard* down to about 1755 (the date of the first edition of Johnson's *Dictionary*), after which a reaction set in, was far less 'careful' in pronunciation and grammar than at present. The natural tendencies of articulation, such as the omission of consonants in certain combinations, and, finally, the pronunciation of old *er* as *ar* (sarvent, farvent, &c.) in a very large number of words, the slurring or reduction of vowels in unstressed syllables, to a far greater extent than at present (as *fortin* for *fortune*, *faggit*, *flaggin* for *fagot*, *flagon*, &c. &c.), were admitted without question in the normal speech of good society. There was far less desire for that kind of 'correct' pronunciation which is based on the traditional spelling. This is proved from the familiar correspondence of the *Paston Letters*, of Queen Elizabeth, of Gabriel Harvey, of the letter-writers in the *Verney Memoirs* (1639-96), of Lady Wentworth and her children (1705-39), as well as from the accounts given of English pronunciation by the more reliable grammarians of the 17th and 18th centuries. The occasional spellings even in literary works by writers of repute during the 16th century, and the rhymes of poets down to far into the 18th century, all point in the same direction. The reaction came from the highly educated middle-class in the time of Johnson, and the personal influence and prestige of this great man and his circle probably contributed largely to the gradual realisation of those ideals of correctness which he sets forth in the preface to his *Dictionary*.

Two points remain to be briefly touched on in this general survey—the relation of the Spoken Language to the English of Literature, and the survival of Regional Dialect among the upper classes.

As regards the first point, it may be affirmed that allowing for the inevitable differences between what is rapidly uttered without preparation, in familiar conversation, and that which is written at leisure, with every opportunity for deliberation, care, and design, the best literary style of any age is identical, in structure, diction, and general cadence and atmosphere, with the best spoken English of that age. This is noticeable in a remarkable degree in the age of Elizabeth, when the very habits of pronunciation are frequently betrayed by the lapses of the writer from the conventional 'correct' spelling, even in such literary works as *Euphues*.

The style of English literature renews its vitality each generation from the colloquial English of everyday life in which, far more than in any outworn purely literary tradition, it has its roots, and from which it draws its nutriment.

Sweet, *A New English Grammar, Logical and Historical*, Part I. (Intro. Phonol. and Accidence), 1892, Part II. (Syntax), 1899; *A History of English Sounds* (1888); H. C. Wyld, *A Short History of English* (2d ed. 1921, contains bibliographies of texts, and recent books).

Works on the Vocabulary of English.—J. B. Greenough and G. L. Kittredge, *Words and their Ways in English Speech* (1902); W. W. Skeat, *Principles of English Etymology* (2 vols. Oxford); L. Pearsall Smith, *The English Language*; G. H. McKnight, *English Words and their Background* (1923). (The books of Jespersen and Bradley, mentioned above, deal chiefly with the vocabulary.)

The Old English Period (Collections of Short Extracts in Prose and Verse).—A. S. Cook, *First Book in Old English* (3d ed.); H. Sweet, *First Steps in Anglo-Saxon* (1897), *An Anglo-Saxon Primer* (1905), *An Anglo-Saxon Reader in Prose and Verse* (1908), *A Second Anglo-Saxon Reader, Archaic and Dialectal* (1887); A. J. Wyatt, *An Anglo-Saxon Reader, with Notes and Glossary* (1919); W. J. Sedgefield, *An Anglo-Saxon Verse Book* (1922).

Old English Grammars.—K. Bülbring, *Altenglisches Elementarbuch* (1902); E. Sievers, *Angelsächsische Grammatik* (1898); H. Sweet, grammatical introduction in *Anglo-Saxon Reader*; J. and E. M. Wright, *An Old English Grammar* (1908).

Dictionaries.—Bosworth-Toller, *An Anglo-Saxon Dictionary* (1882-98), Supplement (1908); A. S. Napier, *Contributions to O.E. Lexicography* (Trans. Phil. Soc., 1906, pp. 265-358); H. Sweet, *A Student's Anglo-Saxon Dictionary* (1897).

Middle English (Collections of Short Extracts in Prose and Verse).—A. S. Cook, *A Literary Middle English Reader* (1915); O. Emerson, *A Middle English Reader*, with grammatical introduction, notes, and glossary (1909); J. Hall, *Early Middle English Reader*, with elaborate notes and glossary (1920); G. MacLean, *Old and Middle English Reader* (1903); Morris and Skeat, *Specimens of Early English*, Parts I. and II., 1150-1390; Gregory Smith, *Specimens of Middle Scots* (1902); K. Sisam, *Fourteenth Century Verse and Prose* (1921).

Dictionaries.—A. L. Mayhew and W. W. Skeat, *A Concise Middle English Dictionary* (1888); F. H. Strattmann (revised by H. Bradley), *A Middle English Dictionary* (1891). [All the Readers mentioned above have full glossaries, or glossarial notes; most editions of M.E. texts are furnished with glossaries. Chaucer's vocabulary is interpreted in the glossaries at the end of Skeat's *Student's Chaucer* (1901), and the same editor's *Works of Geoffrey Chaucer* (6 vols. 1894). Other copious M.E. glossaries are those in Skeat's edition of *Piers the Plowman* (2 vols.), and G. O. Macaulay's *English Works of John Gower* (2 vols. 1901); J. K. Wallenberg, *The Vocabulary of Avenbite of Inuyt* (Uppsala, 1923); and that of Tolkien, based on Sisam's *Reader* (1923).]

Middle English Grammar.—There is only one M.E. grammar, apart from grammatical introductions in editions of texts, and in Readers. L. Morsbach's *Mittelenglische Grammatik*, Part I. (1896) is incomplete, and deals with the classification of the dialects, lists of representative texts, and part of the phonology of the vowels only. Fairly full and practical grammatical introductions are found in the Readers of Morris and Skeat, and Emerson, mentioned above.

Among special works dealing with the grammar of the London Dialect the following may be mentioned: L. Morsbach, *Über den Ursprung der neuenglischen Schriftsprache* (1888); Dölle, *Zur Sprache London's vor Chaucer* (1913); Ten Brink, *Chaucer's Sprache und Verskunst* (revised Kluge, 1899); Frieshammer, *Die sprachliche Form d. Chaucerschen Prosa* (1910). On the grouping of the M.E. Dialects R. Jordan, *Die Mittelenglischen Mundarten*, *Germ.-Rom. Monatschrift* II., and H. C. Wyld, 'S.E. and S.E. Midland Dialect in M.E.' (*Essays and Studies*, vol. vi. 1920), may be consulted. For the dialect of

Chaucer, F. Wild's *Die Sprachlichen Eigentümlichkeiten d. wichtigsten Chaucer-Handschriften* (Leipzig, 1915), is of the highest importance.

Bibliographical Guides to M.E.—J. M. Booker, *Dates, Dialects, and Sources, Twelfth, Thirteenth, and Fourteenth Century Monuments and MSS.* (1912); J. E. Wells, *A Manual of Writings in Middle English* (1916; First Supplement 1919).

History of English since Chaucer.—W. Fianz, *Shakespeare-Grammatik* (1909); W. Horn, *Historische neu-englische Grammatik* (1908), Part I. Phonology; O. Jespersen, *A Modern English Grammar on Historical Principles*, Part I. Phonology (1909), Part II. Syntax (1914); H. T. Price, *History of the Ablaut in Strong Verbs from Caeson to the End of the Elizabethan Period* (1910); W. Vietor, *Shakespeare's Pronunciation, Phonology and Rhyme Index* (1906); H. C. Wyld, *A History of Modern Colloquial English* (2d ed. 1921); R. E. Zachrisson, *Pronunciation of English Vowels, 1400-1700* (Göteborg, 1913).

Select List of Works which illustrate unstudied Colloquial English, 15th to 18th Centuries.—1424-1506: *Paston Letters*, ed. Gairdner (3 vols.); before 1467: William Gregory, *Chronicle* (in Collections of a Citizen of London), Gairdner, Camden Society (1876); 1473-88: *Cely Papers*, ed. Maldon, Camden Society (1900); 1528: *Rede me and be not wrothe*, ed. Horner; 1550-53: *Diary of Henry Machyn*, Camden Society; 1573-80: Gabriel Harvey, *Letter Book*, ed. Scott, Camden Society (1884); 15—: *Queen Elizabeth's Letters to James VI.*, Camden Society (1849); 1593-1626: *Memoirs of Edward Alleyn*, ed. Payne Collier, Shakespeare Society (1843); 1634-75: *Letters of Mrs Basire, in Correspondence of Dr Basire*, ed. W. N. Darnell (1831); 1639-96: *Memoirs of the Verney Family*, ed. Lady Verney (4 vols. 1894); 1708-39: *The Wentworth Papers*, ed. J. J. Catwright (1883). See especially the letters of old Lady Wentworth, Lady Strafford, and Peter Wentworth.

Etymological Dictionaries.—*The Oxford English Dictionary*, ed. Murray, Bradley, Craigie, Onions; *Etymological Dictionary of the English Language* (4th ed. 1910); *The Concise Oxford Dictionary of Current English* (adapted from above), H. W. and F. G. Fowler (1911); *Chambers's Etymological Dictionary*, *Etymological Dictionary of Modern English*, Weekley (1921).

Further and fuller lists of recent works on the history of English in all its stages, including special monographs on O. and M.E., are to be found in H. C. Wyld's *Short History of English*; lists of sources, grammars, and special investigations will be found in the works of Luick, Jespersen, and Zachrisson quoted above, and in Wyld's *History of Modern Colloquial English*.

As it is sometimes quite impossible to give an account of the history of sound change without using a phonetic alphabet, the following symbols are used, when necessary, for greater accuracy. Phonetic spellings are always included in []. The normal spelling of O. and M.E. may on the whole be regarded as phonetic, so that transcription is only needed occasionally to distinguish, for example, between the two sounds represented by *ē* and by *ō*. In the Mod. Period, where the orthodox spelling hardly changes, although the sounds have changed and are changing, transcription is essential. It must be understood that in O. and M.E. the vowel symbols have approximately the 'Continental' values.

Vowels.—*a*=*a* as in Ger. *mann*; *ā*=*a* as in *father*; *æ*=vowel in Engl. *hat*, &c.; *ē*=Fr. *é*; *ē*=Fr. *ê*; *i*=Fr. *î* in *si*; *i* as in present spelling; *ȳ*=Fr. *u* in *dure*, *su*; *o*=Fr. *eu* as in *peu*; *ō*=Ger. *o* in *schon*; *ō*=*aw* as in *saw*; *o*=*o* in *not*; *ū*=*oo* as in *moon*; *u*=Engl. *u* in *put*; *a*=*u* in Engl. *but*; *ȁ*=sound in *curl*, *bird*, &c.; *ə*=common Engl. unstressed vowel in *butter*, &c.

Consonants.—*j*=*j* in Ger. *jahr*, Engl. *y* in *young*; *ŋ*=*ng* as in *sing*; *ʃ*=*sh* as in *ship*, &c.; *ʒ*=*j* in Fr. *jour*; *þ*=*th* as in *think*; *ð*=*th* as in *this*; *s*=always *s*, never *z*; *z*=*z*; *g*=*g* in *go*. (f, l, m, n, p, k, t, r, d, b, w, have same values as in ordinary spelling.) Length marked by *ˉ* over the vowel; stress by *ˈ* over the vowel; nasalisation by *˜* over the vowel, *ã*, &c.

Diphthongs are merely combinations of above symbols: *ai* as in *sight*, *au* as in *house*, &c. Note Consonant combinations, e.g. *dz*=*dge* in *bridge*, *tj*=*ch* in *cheap*, &c.

HISTORY OF THE SOUNDS OF ENGLISH.—§ 1. The external form, that is, the sounds of O.E., underwent certain characteristic changes which wrought considerable differences in the oldest form of our language compared with the parent West Germanic, or with the other, nearest cognate tongues of this group. It is necessary to assume an intermediate stage—W. Gmc.—between Primitive Gmc. and O.E., because, although the phonological differences between W. Gmc. and Gmc. were not very great, there are certain sounds in O.E. which cannot be derived direct from parent Gmc. without the assumption of this intermediate stage which we find preserved in the other W. Gmc. languages. In some ways, especially as regards the vowels, the Old High German dialects are more primitive than the other W. Gmc. languages, though in respect of the consonantal sounds High German is much less primitive. Old English preserves on the whole the original consonant sounds of W. Gmc. which are also found in Continental Old Saxon. The consonant system of W. Gmc. does not greatly differ from that of Germanic.

The treatment of the W. Gmc. vowels in O.E.—We distinguish between *Isolative* and *Combina-tive* sound changes. The former are the result of normal development, and are not determined by the influence of other sounds in the same word. By the period of the earliest O.E. documents the characteristic phonological differences are fully developed. Some of the changes may have begun during the Continental period. The complete isolation of English from other types of Germanic speech produced more far-reaching changes in the original sound system than is found in any of the languages of the same family on the Continent, widely as these have diverged from each other in some respects.

§ 2 *Isolative Treatment.*—1. W. Gmc. *ā* becomes *æ*: O.E. *sæd* 'seed,' O.H.G. *sāt*; O.E. *dæd* 'deed,' O. Sax. *dād*. W. Gmc. *ā* remains in O.E. when followed by *w*, or *g*, + a back vowel: *lāgon* 'they lay,' *sāwon* 'they saw.'

2. W. Gmc. *ǣ* becomes *æ*: O.E. *dæg* 'day,' O.H.G. *tac*; O.E. *æcer* 'field,' O.H.G. *acchar*, &c. When, however, *ǣ* is followed in the next syllable by *a*, *u*, it remains unaltered if only a single consonant intervenes; thus *dæg* has nom. pl. *dagas*, dat. pl. *dagum*, &c. The *æ* develops, however, in the pl. of *cræft* 'strength,' &c., pl. *cræftas*, and so on.

Before nasals also *a* does not change to *æ*, thus *land*, *nama* 'name,' &c.

3. W. Gmc. *ai* becomes *ā* in O.E.; O.E. *ān* 'one,' O.H.G. *ain*, *ein*; *bān* 'bone,' O.H.G. *bain*, *bein*.

4. Gmc. and W. Gmc. *au* becomes *ēa* in O.E. through the stages *eu*, *eo*, the latter of which still survives, in some Old Northumbrian sources: *lēas* 'chose,' Gothic *kauis*, O.H.G. *kous* (= *kauis*); O.E. *deap*, Gothic *darupus* 'death,' O.H.G. *tōt* (with change of *au* to *ō* before *t*); O.E. *hlēapan* 'leap,' O.H.G. *lorfan*.

5. Gmc. and W. Gmc. *eu* becomes O.E. *ēo*; O.E. *lēosan* 'choose,' Goth. *krisan*; O.E. *lēof* 'dear,' Goth. *lubs*, O.H.G. *luf*. The diphthong still retains its primitive form occasionally in some of the earlier Glosses, e.g. *steupfæder* 'stepfather' in Epinal Gl., later *stēop*.

6. The vowels *e*, *i*, *u*, *o*, whether long or short, remain in O.E. unless altered by Combinative change.

7. There was a vowel in Gmc. and W. Gmc. which was originally a nasalised *a* [ã]. It had arisen in Gmc. in the combination *-anh-*. The vowel in this position became nasalised (a sound

somewhat resembling French *an*), then the *n* disappeared. Thus there was an old past tense of the verb *to bring*—**branhita*, this became **brāhita*. In O.E. this nasalised *ā* became *ō*, and the nasalisation disappeared, the vowel being lengthened. In O.H.G. we find *brachta* 'brought,' and *dachta* 'thought,' but in O.E. *brōhte*, *pōhte*. The nasalisation disappeared in time in the other W. Gmc. languages; in O.E. alone the vowel was previously rounded to *ō*. Part of the process, as we see, was Combinative, but the main part, that we are concerned with here, namely, the rounding of the nasalised *ā*, is Isolative.

§ 3 *Combinative Changes.*—1. *Fracture.*—This is the name given to a process whereby, at a very early period, the vowels *i*, *e*, *æ* and *ē* were diphthongised when they occurred before certain consonants or combinations of consonants. The sounds which produced the diphthongs were *h*, alone, or followed by another consonant; *ll*, and *l* followed by another consonant; *rr*, and *r* followed by another consonant. *i* became *iu* and then *eo* in the Merc. dialects (cf. § 88, 3); *e* became *eu* and then *eo*, so that in these dialects there is no difference between the result of the fracture of *i* and *e*. *æ* became *æu* and then *ea*; *ē* became *ēu* and then *ēa*. *i* and *e* undergo no fracture before *ll* and other *l*-combinations except those with *c* and *h*.

(a) Fracture of *i*: *meox* and *miox*, from **mihs-* 'dung'; *meolcum* and *miolcum* 'milk,' dat. pl. from **milk-*; *iorre* 'angry,' W. Sax. *ierre*, Merc. *eorre* (cf. § 88, 3, below).

(b) Fracture of *e*: *fehtan* 'to fight,' O.H.G. *fehthan*; *seoh*, imperat. 'see,' from **seh*; *seolh* 'seal,' from *selh*; *heorte* 'heart,' O.H.G. *herz*, O. Sax. *herto*; *weorðan* 'become,' O.H.G. *werden*; *eorpe* 'earth,' O.H.G. *erda*.

(c) Fracture of *æ*: *seuh* 'saw,' from *sæh*, cf. O.H.G. *sah*; *feahht* 'fought,' *feallan* 'to fall,' O.H.G. *fallen*; *eald* 'old,' O.H.G. *alt*, O. Sax. *ald*; *healf* 'half,' O.H.G. *halb*; *earn* 'poor,' O.H.G., O. Sax. *arn*; *wearp* 'became,' O.H.G. *warth*; *earn* 'eagle,' O.H.G. *arn*. (N.B. this *æ* is always from an earlier *a* which survives in other Gmc. languages.)

(d) Fracture of *ē*: the only example is O.E. *nēah* 'near,' from *nēh*, O.H.G. *nāh*.

2. W. Gmc. *ā* becomes *ō* before a nasal consonant in O.E.: O.E. *mōna* 'moon,' O.H.G. *mānō*; *nōmon*, pret. pl., 'they, &c., took,' O.H.G. *nāmun*. This is the vowel which, as we saw in § 2, 1, normally became *æ* in O.E.

3. W. Gmc. *ā* before a nasal consonant is rounded to *o* in Early O.E., especially in W. Sax., but this rounding is not universal, and *a*-forms occur in all dialects; thus *monn* and *mann*, *hond* and *hand*, *long* and *lang*. In later W. Sax. the *a*-forms preponderate.

4. Primitive O.E. *ā* becomes *ō*. This process is exactly similar to that described in § 2, 7, but part at least of it is of a later date, and the whole process must be considered as typically English. The loss of the nasal consonant before *h* is a Gmc. change, and the *ā* arose in the most primitive Gmc. period. The *ā* we are now considering arose in the earliest English period in the combinations *-ans-*, *-amf-*, *-anp-*. The actual rounding of *ā* of both origins may have been synchronous. Thus an original *gans* 'goose' (as in O.H.G.) became *gās*, and this, before the earliest documents, became *gōs*. Other examples are: *sōfte* 'soft,' O.H.G. *samfto*; *nōp* 'courage,' from **nanp*, cf. Goth. *nanp-jan* 'to venture'; *tōp* 'tooth,' from **tanp*, cf. O.H.G. *zand*.

5. Lengthening of *i*, *ū* (nasalised *i* and *u*) on loss of nasalisation. These vowels arose under the same conditions as *ā* discussed in § 2, 7, and § 3, 4, but they undergo no qualitative change.

Examples: *sip* 'time, journey'; cf. Goth. *sinþ-s*; *cūþ*, 'known', O.H.G. *kund*, Goth. *kūnþ-s*; *mūþ*, 'mouth', from **mump*; cf. O.H.G. *münd*.

6. Diphthonging of Primitive O.E. *e*, *æ*, *æ* after front ('palatal') consonants. (For origin of *æ* and *æ* cf. § 2, 1 and 2.) This process is typical of the W. Sax. dialect, and occurs after the consonants *č*, *g*, *st*, where the above vowels become *ie*, *ea*, *ēa* respectively. The non-W. Sax. dialects preserve the vowels unchanged. The diphthonging occurs in W. Sax. before the period of the earliest documents. Thus Prim. O.E. *čæf*, non-W. Sax. *čæf* (*čef*), becomes W. Sax. *čæf* 'chaff'; W. Sax. *geaf*, pret. sing. 'gave', non-W. Sax. *gæf* (*gef*); W. Sax. *gēafon*, non-W. Sax. *gæfon* (*gēfon*), pret. pl. 'gave'; *gēfan* 'to give', non-W. Sax. *gefan*, O.H.G. *geban*; *gēpan* 'boast', non-W. Sax. *gēpan*, O.H.G. *gelfan*; *scēal* 'shall', non-W. Sax. *sčæl* (*sčel*); *scield* 'shield', non-W. Sax. *sčield*; *sčēap* 'sheep', non-W. Sax. *sčēp*, became *stēp*, O.H.G. *schāf*.

7. *i*- and *j*-mutation.—This process, which is one of the latest of the important Combinative changes in Early O.E.—later than all those hitherto mentioned—consists in the fronting, or, as some prefer to call it, 'palatalising,' of back vowels, *a*, *ā*, *u*, *ū*, *o*, *ō*, when the front vowel *i* or the front open consonant ('spirant') *j* (as in German *jahr*, or English *year*) follows in the next syllable. The intervening consonant is first modified by shifting the place of articulation forward in the direction of the front *i* or *j*, and this in its turn 'fronts' the preceding vowel. The process is essentially a 'fronting' process, except in one case, that of *æ*, which, as we shall see, being a front vowel, is merely 'raised' to *e*. The results of this process are found in the oldest documents. In addition to the simple vowels, *i*-mutation affects also the diphthongs, especially in W. Sax. *ēa* and *ēō*, both becoming *iē*. We know that *i*-mutation is later than the other Combinative changes hitherto dealt with, because vowels which result from these earlier processes are affected by this one. The process is perhaps the most important and far-reaching of all the O.E. Combinative changes, since its results remain at the present time, and there are innumerable cases of variants in the same 'root' which cannot be understood without a knowledge of it. Examples:

- (a) of *ā*: *slægen*, p.p. 'struck,' from **slagin*.
- (b) of *ā*: (cf. § 2, 3) *dæl* 'part,' from **dāli*, cf. *dāl*, from **dāla*; also *dēlan* 'to divide,' from **dāl-jan*; *tæcan* 'point out, teach,' from **tāk-jan*, cf. *tāc-n* 'sign, token.'
- (c) of *æ*: *settan*, vb. 'set, place,' from **sætt-jan*, cf. *sæt* 'sat,' pret. of *sittan*.
- (d) of *ō*: *dēman* 'to judge,' cf. *dōm* 'judgment,' and O. Sax. *dōmian*; *cwēn* 'woman, queen,' from **cwōni*, W. Gmc. **kwāni* (cf. § 3, 2); *tēp* 'teeth,' from **tōpi*, cf. *tōp* 'tooth'; *gēs* 'geese,' from **gōsi* (for this *ō* cf. § 3, 4).

- (e) of *ō*: *exen*, pl. of *oxa* 'ox' from **ox-in*.
- (f) of *ū*: *brȳd* 'bride,' cf. Goth. *brūpi*; *cȳ* 'cows,' from **kū-i*, pl. of *cū*, cf. Provincial *kȳe*; *cȳpan* 'to make known,' from **cūp-jan*, from *kunþ-jan*, which survives in Gothic, cf. § 3, 5.
- (g) of *ū*: *fyllan* 'to fill,' cf. O.E. *full* 'full'; *pytt* 'pit,' from **puttjo*, early loan-word from Lat. *puteus*.

- (h) of *ēa*: *hēran* 'hear,' from **hēar-jan*; *flēman* 'put to flight,' from **flēam-jan*; *iernþu* 'misery,' from **earmþu*, cf. *earm* 'poor'; *bieldan* 'to encourage,' from **beald-jan*, cf. *beald* 'bold.' The diphthongs *iē* only occur in W. Sax., cf. § 85, 2. For forms in other dialects, cf. § 86, 1. In Late W. Sax. *iē* becomes either *y* or, in other areas, *ī*.

THE MIDDLE ENGLISH PERIOD (c. 1100-c. 1400).—§ 4. The vowel system by the end of the O.E. period was approximately the following: *Long vowels*, *ā*, *ē*, *ī*, *ō*, *ū*, *y*; *short vowels*, *a*, *æ*, *e*, *i*,

o, *u*, *y*; *long diphthongs*, *ēa*, *ēō*, (*iē*); *short diphthongs*, *ea*, *eo*, (*ie*).

§ 5. *Spelling*.—This was at first unaffected by Norman influence, but it was beginning to reflect, sporadically, the gradual sound changes that were overtaking English, such as the simplification of the old diphthongs, and the weakening of the vowels of unstressed syllables to a single sound, generally written *e* later on. In the Late O.E. period, however, we find that *a*, *e*, *u* in unstressed syllables were often confused, and one written where, historically, another belonged.

During the 12th century increasing signs are seen in the MSS. of Norman orthography, notably the writing of *u* (or *v*) for O.E. *y*, on the model of the French spelling for a sound which was presumably identical, and the writing *ou* for the [ū] sound as still in French; the purely graphic substitution of *o* for O.E. *u* (some for O.E. *sunu* 'son,' &c.), especially in the neighbourhood of *n*, *m*, *w*. The new diphthongs, whether in English or French words, were written *ai*, *ei*, *au*, *ou*, symbols which are unknown in O.E., except *ea*, which occurs sometimes in Kentish texts. It may be assumed that, on the whole, the vowel symbols still had their so-called Continental values: *e*=[e], *i*=[i], &c. Length is sometimes expressed by doubling the letters, *saaf* 'safe,' *good* 'good,' but is generally unmarked. When necessary for clearness, the phonetic symbols will be used in the following, placed in [].

§ 6. The consonants underwent comparatively little change. O.E. *č*, *st* are written *ch*, or, medially, *tch*; *sch*, *sh*, *ssh*, *ss* respectively, and no doubt had their present-day sounds. O.E. *ġ* initially is often written *z*, a modification of the O.E. symbol *ġ*, and, later, more commonly *y*. O.E. *g* between back vowels was an open consonant ('spirant'), and in this position it was weakened to *w* in M.E., e.g. *lawe* 'law,' O.E. *lagu*. O.E. *čg* in *bryčg*, *byčgan* 'bridge, buy,' &c., attained the present sound, and was written *gg*: *brigge*, *biggen*, &c. The Continental symbol *g*, unknown in Engl. MSS. before the Conquest, was used for the stop consonant as at present: *gōd* 'good,' &c. The back open voiceless consonant, as in Scots *loch*, is written either *h* or, later, *gh*, as in *ruh* 'rough.' The O.E. symbol *p* is generally replaced by *w* or *uu*. The symbol *þ* survives alongside of *th* well into the 15th century.

Early in the M.E. period the back voiceless stop is increasingly expressed by *k*, especially before front vowels, *king*, *kēpen* 'keep,' &c.; later also *ck* when final, in which position *c* would express [s] to a Norman. *c* for *s* is sometimes used in English words, cf. *mice*. *c*, however, is retained initially before back vowels where no ambiguity could occur; thus we still write *cold*, *cot*, *come*, &c. The early printers did not cut a special type for *z*, but used *z*, which is also found in some late 15th-century documents instead of *z* or *y*. This explains why we still write *Capercaillie*, *Dalziel*, *Monzie* [keipəkə'li, diəl, mənʒ], &c. *Mackenzie* owes its present pronunciation to the spelling, which undoubtedly was intended to express [mekənʒi].

§ 7. The above vowels underwent important changes in the M.E. period, involving both quantity and the actual quality of the sounds.

Changes in Quantity.—M.E. *Vowel Lengthenings*.—(a) Late in the O.E. period short vowels were lengthened before the combinations *ld*, *nd*, *mb*, *rd*; thus *ald* (§ 87, 4) became *āld* 'old,' *ēld* (the result of the fractured form) became *ēald*, *ēild* 'child' became *ēald*, *cāmb* 'comb' became *cāmb*, *wōrd* became *wōrd*, &c.

(b) During the 13th century the short vowels *e*, *a*, *o* were lengthened in words of two syllables where only one consonant intervenes, as in *tākan* 'take,' which became *tāken*, *hōpa* 'hope' became *hōpe*, *mēte* 'meat' became *mēte*, &c. The lengthened

syllables in these cases ended in a vowel, the division originally being *me-te*, &c. These are called open syllables, and the process is known as *lengthening in open syllables*. At a later date *i* and *e* are lengthened under the same conditions in some dialects, and by the 14th century undergo a further change to tense *ē* and *ō* respectively. They then share the subsequent fate of ordinary M.E. *ē*, *ō*, for which see §§ 31, 33, below. Examples: Late M.E. *wēke* 'week'; O.E. *wicu*, *wōde* 'wood'; O.E. *wīdu*.

§ 8. *M.E. Vowel Shortenings*.—(a) *Shortening before groups of consonants*.—O.E. long vowels were shortened in M.E. before doubled (long) consonants, before most combinations of consonants other than those mentioned in 7 (a). Before these also, when another consonant follows, long vowels were shortened, and those originally short were not lengthened: *hiddle*, pret. of *hīdan* 'hide'; O.E. *hýdde*; *fēlde* 'fel'; pret. of *fēdan*, O.E. *fīdde*; *wēpte*, pret. of *wēpen*, O.E. *wýpte*; *sōfte* 'soft', O.E. *sōfte*; *dēpthe* 'depth' cpd. with *dēpe* 'deep'; *gāstliche* 'spiritual', O.E. *gāstlice*; *gōsling* cpd. with *gōs* 'goose'; *hāllwen* 'hallow' cpd. with *hōli* 'holy'; pl. *childe* cpd. with *child*; pl. *lāmbre* cpd. with *lōmb* 'lamb', &c. It will be seen that many differences in quantity in forms of the same root in Mod. Engl. can be explained by this principle.

(b) *Shortening of first of three syllables*.—*Hōlida* cpd. with *hōli*; cf. pl. n. *Whitaker*, where the first element is O.E. *hwita* 'white'. The vowel in an open syllable (§ 7 (b)) where this is the first of three is not lengthened: cf. *Beverley* by the side of uncompound *beaver*, O.E. *beofor*, M.E. *bēver*.

(c) *Long vowels shortened in unstressed syllables*.—There are innumerable examples of this in place-names compounded with O.E. *tūn* 'town', where we now get [tən] (written *-ton*), *Bamp-ton*, &c.; cf. old *Kingston* with Mod. *Kingstown* in Ireland; those in *-ham*, O.E. *hām*, as in *Birmingham*, &c. cpd. with uncompound *home*. Cf. also *hussif*, O.E. *hūs wif* 'house-wife'.

Qualitative Treatment of the Vowels in M.E.—§ 9. O.E. *æ*, *a*. To judge by sporadic spellings with *e* it seems probable that before the end of the O.E. period *æ* had in several dialects, including W. Sax., been raised to *e*—set for O.E. *sæt* 'set'; *pet* for *pæt*, *wes* for *wæs*, &c. (On the earlier O.E. change to *e* in the dialects cf. §§ 87, 5; 88, 1.) In another area, however, in the Midlands, and perhaps first of all in the East, *æ* instead of becoming *e* is retracted to *a*, and in the first half of the 12th century we find *was*, *bar*, O.E. *bær*, 'boar', *spac*, O.E. *spræc* 'spoke', side by side with the old spelling *æ* and a few *e* spellings. The *a*-forms speedily become the most widespread in practically all dialects, including that of London. Chaucer knows no others. The *a* of this origin is lengthened according to § 7 (b), e.g. O.E. *læt* 'slow'; M.E. *lāte*, 'late'. O.E. *a* undergoes no change in Early M.E., and therefore differs in no respect from the new *a* from *æ*, O.E. *fæt* 'vessel', pl. *futu*, M.E. *fat*—*fāten*. This *a* in so far as it remained short was gradually fronted during the M.E. period in the direction of the Mod. sound (cf. § 25).

§ 10. O.E. *ā* (cf. § 2, 3, above) became *ō*=[*ɔ*] in the Sthn. and Midland. The change, in the way of some slight rounding, must have begun very early, and before the introduction of the earliest French loan-words with *ā*, *fāme*, &c., since none of them ever have *ō*. The 12th-century texts still write *a* as a rule, but Peterb. Chron. writes *mor(e)*, O.E. *mār(a)* 'more' several times. During the 13th century the archaic spelling *a* is often used, sometimes alongside of, sometimes instead of, *o*, even in those dialects where *ō* had certainly developed; but by the beginning of the next century *o* is practically

the universal spelling in all areas where the rounding took place. Examples: *hōm*, O.E. *hām*, *bōl(e)*, M.E. *bāt* 'boat'; *rōd*, O.E. *rād* 'rode'; *tōlde*, O.E. *tālcde* 'told'; *gōst* 'spirit', O.E. *gāst*. The shortenings mentioned § 8 (a) are earlier than this rounding, as is seen from *Stān-lei* cpd. with *stōn*, O.E. *stān*, &c., *ān*, indef. art (unstressed), cpd. with *one* 'one', O.E. *ān*, and the suffix *-hām* by the side of *hōm*, &c. This *ō* had the same sound as O.E. *ō*, lengthened according to § 7 (b), and must be kept distinct from the other O.E. and M.E. *ō* below. It is sometimes written *oa*, *loaf*, O.E. *hlāf* 'loaf', &c. For Nthn. fronting of O.E. *ā* cf. § 91, below.

§ 11. O.E. *æ*. This sound in O.E. had two distinct sources, which it is necessary to distinguish, as their fates are in some cases different. (a) What we may call Prim. O.E. *æ* or *æ¹*, from W. Gmc. *ā* (cf. § 2, 1, above) becomes [ē], written *ē* in O.E. in a very large area of the country before the earliest written documents, but remains as *æ* so written in Wessex and part of the S.E. Midl. (For dialectal distribution of *æ*, *ē*, cf. §§ 85, 3; 86, 3; 95 (b); 96 (b) and (c); 97 (b) and (c), below.) In M.E. those dialects which preserved this *æ* raised it to [ē], the other dialects had [ē] instead. Chaucer's rhymes show that the London dialect used the [ē] type in a preponderating number of words, although the other type was by no means unknown.

It may be noted that the sound [ē] is sometimes, but not at all systematically, written *ea*, otherwise it is impossible to distinguish between the types except by examining the rhymes in poetry. Examples of words containing *æ¹* are: *rēde* 'council', O.E. *rād*; *spēche*, O.E. *spīc*; *wēren* 'were', O.E. *wērōn*; *brēth(e)* 'breath', O.E. *brāþ*, &c.

§ 12.—(b) The other O.E. *æ*, which we may call *æ²*, was the result of *i*-*j*-mutation of O.E. *ā* (cf. § 3, 7 (b)). This sound is far more constant in O.E. than *æ¹*, and, apart from Kent and certain areas in the extreme East, it survived during the O.E. period. In Late O.E. and Early M.E. this *æ²* was also raised to [ē], while the other type remained [ē] as it had been in O.E. The treatment of *æ¹* and *æ²* becomes an important dialect test in M.E. (cf. §§ 93 and 96). In the dialect of Chaucer *æ²* the slack type [ē] is usual, though the rhymes show that the Kentish or Essex type [ē] also existed. On the whole, it may generally be assumed that words containing *æ²* in M.E. will have the [ē] sound, the area where the tense type obtains being comparatively small. The vowel of this origin is also written *ea*. This symbol is an indication of the slack sound. Examples are: *tēche* 'teach', O.E. *tēcan*; *ēvre* 'ever', O.E. *æfre*; *ēni* 'any', O.E. *ænig*; *hēth* 'heath', O.E. *hæþ*. Note that Chaucer rhymes *brēp*—*hēp* in lines 5 and 6 of the *Prol.* Gower, a Kentishman, writes *ie* for *æ²* in *diel*, 'part', showing his typical tense form, compared with Chaucer's *dēl* [dēl]. It is very important to make the distinction in pronunciation between the two sounds [ē, ē] in M.E. The subsequent history of the two sounds is different up to a point. They are both [i] now, but the tense [ē] changed into its present sound perhaps a century earlier than the slack, and the present type of the latter did not come into use in Received Standard till much later still. (For other sources of M.E. [ē, ē] cf. § 7 (b); §§ 13, 20, 22, 23.)

§ 13. O.E. *ē*.—This sound, which may arise from the *i*-mutation of *ō* (cf. § 3, 7 (d)), from either *æ¹* or *æ²* in certain dialects, as just described, from *i*-mutation of *ēā* in non-W. Sax. (cf. § 23), as a special S.E. treatment of O.E. *ȳ* (cf. § 96), or from the lengthening of *i*, remains unaltered during the greater part of the M.E. period, towards the end of which it tends towards the present sound [i]. As early as the 12th century sporadic spellings, such as *siche* (Brut) for O.E. *sēcan*, tend to show that the sound, in some areas at any rate, was beginning to change

very early. Tense *ē* of any of the above origins is occasionally written *æ* in M.E., a spelling which always indicates the tense vowel. See examples under references to various sources of the sound.

§ 14. O.E. *ī*, as in *wif*, 'wife, woman,' *writan* 'write,' *milt*, *blind*, &c. survives late into the M.E. period unaltered so far as we know. In the first third of the 15th century spellings like *bleynd* 'blind' point at least to the beginning of diphthongisation.

§ 15. O.E. *ē*, *ē*, *ō*, and *ū*, unless lengthened according to § 7 (b), above, remain unaltered in M.E.

§ 16. O.E. *ō* in *bōc*, *tōp*, *fōda*, *gōd*, *mōna*, *lōcian*, &c. was a tense vowel, and during the M.E. period gradually developed towards [ū]. The above words are normally written *bōk*, *book*, *tooth*, *good(e)*, *mon(e)*, *moon(e)*, *loke* 'look' in M.E., where the *oo* implies no more than length. From the 14th century onwards, however, as very occasionally even earlier, we find the spellings *bouk*, *goud*, *louke*, &c., where *ou* is the normal M.E. spelling of the sound [ū]. Although it might be rash to assume that the present-day vowel, as in *moon*, &c., was fully developed as early as the first half of the 14th century, these spellings undoubtedly point to a movement in that direction. It is probable that by the end of the century the new vowel was established over a wide area. This tense *ō* is never rhymed by good poets in M.E. with the other *ō* of §§ 7 (b) and 10. These sounds were different in O.E., they are different now, and they were certainly quite different in M.E. For the Nthn. development of O.E. *ō* cf. § 91.

§ 17. O.E. *ū*, as in *mūp* 'mouth,' *hūs* 'house,' *hū* 'how,' &c., is generally written *ou* or *ov* after the middle of the 13th century, and in some texts earlier. Thus *hou*, *south*, &c., imply no change in sound. This old *ū* was never caught up by the new *ū* from *ō*—that is, there never was a time when old *mōna* 'moon' had the same vowel as old *tūn* 'town.' Before the new *ū* was fully developed old *ū* had begun to change, and the beginnings of the subsequent diphthongisation must have started. We have no graphic evidence of this, however, during the M.E. period.

§ 18. O.E. *ȳ*.—This original vowel, whose chief source in native English words was the *i*-mutation of *ū* (cf. § 3, 7 (f)) already in O.E., appeared in three forms (cf. §§ 97; 92 to 97), *ī*, *ē*, *ȳ*. The London dialect prefers the *i*-type—*brīd* from O.E. *brȳd* 'bride,' *hīden*, O.E. *hȳden* 'hide,' *mīs* 'mice,' O.E. *mȳs*. The history of this *ī* is precisely that of original *ī* (§ 14). The S.E. types *hēden*, *mēs*, come under M.E. *ē* (§ 13); the surviving O.E. *ȳ*-type is preserved chiefly in the S. and S.W. and W. Midl. It gradually disappears in native words nearly everywhere in favour of the *i*-type. In those areas where it survives it is written *ui*, or *uy* in M.E.

The sound occurs also in N. French loan-words such as *sūre*, *pūre*, *fortūne*, *aventūre*, &c. The sound survives in these words well into the Mod. period (§ 40).

§ 19. O.E. *ȳ*.—In those dialects where it survives in native Engl. words this sound is written *u* in M.E. Its main source was the *i*-mutation of *ū* (§ 3, 7 (g)). The same three types of the short are found in M.E. as of the long, with approximately the same distribution, except that more *e* and *u* forms of the former are found in the London dialect than of the long. The *i* and *e* types, of which the former are the prevailing forms in London, undergo no further change, being treated like original *ī* and *ē* respectively. The vowel of the *u*-type is retracted in the early Mod. period, and became identical with M.E. *ū*, whose fate it therefore shares. The subsequent history of this sound belongs to the Mod. period (cf. § 39). In M.E. the same word may

occur (in Chaucer) in more than one form. Examples of *u*-type in M.E. are *russehe* 'a rush,' *muchē* 'much,' *bundel* 'bundle,' *hull* 'hill,' *bury*, old dat. sing. of *burg* 'town,' O.E. dat. *byrig*; *e*-forms are *lnele*, *fulfelle* 'fulfil,' O.E. (W.S.) *fyllan*, *hesse* 'kiss,' vb., O.E. (W. Sax.) *cyssan*, &c.; *i*-forms: *milke* 'milk,' W. Sax. *mylen*, *thanne* 'thin,' W. Sax. *pyne*, *bisie*, W. Sax. *bysig*, *pitte* (also *putte* in Chaucer), W. Sax. *pytt*, 'pit.' The *ū* [y] sound is common also in Norm. Fr. words: M.E. *jugge* 'judge,' *juste*, &c. This vowel has precisely the same history as the native Engl. sound.

Simplification of O.E. diphthongs in M.E.—§ 20. O.E. *ēa* became *æ*, and is so written, occasionally, in Late O.E. This spelling still survives in Early M.E., but *e*, together with the traditional *ea*, is more frequent. In later M.E. *e* is the normal spelling. There is no doubt that the sound very early became [ē], and was thus identical with that derived from the lengthening of O.E. *ē* (§ 7 (b)) and that derived from O.E. *æ*¹ and *æ*² (§§ 11 and 12). Examples in M.E. are *dēthe* 'death,' O.E. *deāp*, *dēfe* 'deaf,' O.E. *deāf*, *chēs* 'chose,' O.E. *čēas*, pret. sing. It would be quite accurate to say that the vowel in these and similar words was derived from Late O.E. *æ*.

§ 21. O.E. *ǣ*.—The only source we need consider here is that derived from the O.E. fracture diphthong *ea* (§ 3, 1 (c)). This was also monophthongised to *æ* in Late O.E., and shares the fate of original O.E. *æ* (§ 9). Thus O.E. *hearn* becomes *hærm*, whence M.E. *herm* and *harm*; *geard* 'yard' becomes *yærd*, whence M.E. *yard* and *yærd*. The London dialect usually has the *ā* type, but Chaucer still uses *yærd*. In the combination *ea* + *ld*, O.E. *eald* 'old,' *beald* 'bold,' the same change to *æld*, *bæld*, takes place and this vowel undergoes lengthening, so that we get Late O.E. *æld*, *bæld*, whence M.E. *æld*, *bæld*, with [ē] from *æ*² as in § 12.

The distribution of this fractured type is a dialect problem (cf. §§ 95 and 96). In the greater part of the Midland area, however, the fracture of *æ* before *l*-combinations does not take place, and instead of *eald*, &c., we get Late O.E. *āld*, *bāld*, *cāld* 'cold.' This early became the prevailing London type, and indeed it had spread over nearly the whole country by the end of the 14th century. This *ā* is treated in M.E. exactly like the other O.E. *ā* (§ 10), and is rounded to *ō*, so that we get very widely *ōld*, *bōld*, *cōld*, in M.E.

§ 22. O.E. *ēō*.—The history of these diphthongs, both long and short, may be treated together. (1) In some areas, especially in the extreme East, *eo* and *ēō* were monophthongised as early as the 10th century to *e* and *ē* respectively. (2) In others farther West and South the diphthongs were retained as such, and went apparently through the following stages [*eo* < *eo* < *ē*]. This last stage is probably reached in the early 12th century, and the rounded vowel is very soon unrounded to [ē], thus arriving by a different process at the same result as the first-mentioned type. The *ē* of this origin is invariably tense [ē]. This is the London type, derived perhaps by process (2). (3) In the more Westerly areas of the Sth. and Midl. the process followed is (2) above, but on reaching the [ē] stage, instead of becoming [ē] the vowel is raised to [y], thus retaining its rounding. For this sound the symbol *u* is often used, as for the other similar sounds discussed in §§ 18 and 19. (For the distribution of the types see §§ 92 and 95.) Examples of the London type are, for the long, *dēre* 'dear,' O.E. *dēor*, *chēsen* 'to choose,' O.E. *čēosan*, *hēld*, pret. 'held,' O.E. *hēold*; for the short, *erthe* 'earth,' O.E. *eorpe*, *herthe* 'heart,' O.E. *heorte*, *nether*, O.E. *neopor*.

§ 23. O.E. *eo*.—These diphthongs only occur in W. Sax. (§§ 3, 6; 3, 7 (h); 85, 2). In those M.E.

dialects where they exist they are expressed by the spelling *u*, which stands for the Late W. Sax. *y*, e.g. W. Sax. *hyrde* 'shepherd,' M.E. *hurde*; W. Sax. *ieldu*, *ylidu* 'age,' S.W. M.E. *ulde*; W. Sax. *hēran*, *hīran*, S.W. M.E. *hūren*, &c.

The mutation of O.E. *ē* in the non-W. Sax. dialects is *ē*, and this survives, so written in M.E., e.g. *hēron* 'hear,' from O.E. *hēran*, *ēlde* 'age,' O.E. *ēlū*, *herde* 'shepherd.'

§24 In the Late M.E. period the following vowels were in use in the Sth. and Midlands: [ā, ā, ē, ē, ō, ȝ, o, ū, ī, ȝ], and the diphthongs [ai, oi, au, ou, eu, iu].

THE MODERN PERIOD.—§25. *Changes in Stressed Vowel Sounds since c. 1400.*—M.E. *ā*.—This sound has been fronted to [æ] by an isolative change. There is no doubt of the fact; the only question is, When did the present sound develop? It is not till 1653 that Wallis, and in 1685 Cooper, describe a vowel which can only be the present sound in *bat*, *cap*, *dash*, *grand*, *hat*, &c. On the other hand, we get spellings such as *sedress* c. 1420, *thankyng* 'thank' 1442, *wetch* 'watch' 1469, *jesper* c. 1465, and so on, which seem to show that the full M.E. sound was no longer pronounced, at least in some circles. Shakespeare in *Ven.* and *Ad.* rhymes *scratch*—*wretch*, which would hardly have been possible had the old sound still existed. It would probably be safe to say that in the best London English the new sound came into use rather later than in some provincial dialects, but that it was established in the former by the end of the 16th century.

§26. *The combination -al*.—This first became [au], and then was gradually monophthongised to the present [ɔ]. The latter process will be dealt with under the treatment of M.E. *au*, §36. During the 15th century such spellings as *Saulysbury*, *Tawbot*, *cawbyrd* 'called,' *schawl* 'shall,' show at least that the diphthong had already developed.

§27. *M.E. ā after w, wh, qu*.—In words like *was* (when stressed), *wash*, *what*, *quality*, &c., the vowel is rounded to [ɔ]. The process is one of rounding, and presumably took place when the vowel was still in the [ā] stage. *Wosse* is written in the third quarter of the 15th century for *was*, and the same spelling for *wash*, c. 1550. Watson, 1593, rhymes *songs*—*swans*. The *o*-spellings do not become very frequent till the middle of the 17th century. The words *quality*, *quantity*, were long pronounced by some speakers with [æ], and this persisted into the first third of the 19th century among old-fashioned persons. On the other hand, *quollity* occurs as early as 1683 in the Verney Memoirs.

§28. *M.E. ā before w, f, th (þ), and r*.—In these positions *ā* normally became [æ], according to §25, but was subsequently lengthened. Thus *path*, *bath*; *pass*, *last*; *laugh* (Late M.E. *lāf*), *chaff*; *are*, *hard*, &c., were pronounced in later 16th-century English and down to well on in the 18th century among some speakers as [pæθ, pæs; læf, tʃæf, ær, hær], &c., as in the S.W. of England and in many parts of America to-day. This long front vowel was subsequently retracted to [ā], the present sound in Received Standard English. The lengthening probably took place during the first part of the 16th century; the later retraction, at varying dates among different classes of speakers. There are indications that among some speakers [ā] existed already in the late 17th century. This is the chief source of present-day [ā].

§29. *M.E. ā*.—This sound was first fronted and then diphthongised to the present sound. The process was probably [ā-æ-ē-ē-ē]. As early as c. 1430 Bokenam writes *credyll* for M.E. *crādel* 'cradle,' and in 1420 the rhyme *cāre*—*wēre* occurs. Other 15th-century spellings are *came* 'came,' *take* 'take,' &c. It is clear that some sort of fronted

vowel is indicated, but it is impossible to say which precise stage in the series was reached at a given time. In the 16th century Ld. Buckhurst rhymes *speake*—*make*, and Spenser states—*seates*, which almost certainly points to [ē]; cf. §31. The present-day diphthong is first definitely described by Batchelor in 1809. If a front vowel had already arisen as early as the first third of the 15th century, it seems probable that in Chaucer's day the old M.E. *ā* could no longer have been pronounced. The shift towards the present sound had at least begun.

§30. *M.E. ē=[ē]*.—This vowel, no matter what its origin (cf. §§11, 13, 22, 23), has been merely raised to [i]. There are plenty of 15th-century spellings with *i*, *y*: *hyre* 'hear,' *myte* 'meet,' *dyme* 'deem,' *symed* 'seemed,' *spyde* 'speed,' &c. These spellings are very frequent in the 16th century, Q. Eliz. being especially prone to them in her letters. From the moment that these spellings occur it can hardly be doubted that the new sound has developed, or at least one which hardly differs from it.

§31. *M.E. ē=[ē]*.—We have seen that this vowel had numerous sources, and that it was kept distinct from the other *ē* in M.E. rhymes. It has now caught up the tense *ē*, and there is no difference in sound between *meet*, M.E. *mīten*, always tense, and *meat*, M.E. *mīte* (with lengthened vowel), originally slack. The first change was that when [ē] became [i], the other *ē* became tense. The rhymes as late as Pope, and even as Cowper, show that in a large number of words this type, with [ē], remained in use in such words as *sea*, *seat*, *cheat*, *heat*, &c., for a long time. On the other hand, there is evidence, rather doubtful for the 15th, quite positive for the 16th and 17th centuries, that among some groups of speakers the [i] sound had already developed. In 1528 *clean* (M.E. [ē]) rhymes with *been*; in 1550 the spellings *brylyng*, *spykyng*, occur in Machyn; *būve* (O.E. *veāfan*) in Gabr. Harvey's letters 1573–80; and Q. Eliz. writes *bequived* 'bequeathed.' These forms make it certain that the new type already existed, but it was not yet widespread. There is plenty of evidence for the existence, side by side, of both forms in the 17th and 18th centuries, though during the latter the new type was gradually taking the place of the old more and more among a wider circle and in an increasing number of words. What has happened since Pope is not that his pronunciation of *heat* to rhyme with *meat* has changed by natural development into ours, but that his type has been abandoned and another substituted. Our pronunciations of *great*, *break*, *steak*, are probably survivals of the older type. Note that before *r* the vowel did not become tense, e.g. in *bear*, M.E. *bēren*, *tear*, vb., M.E. *tēren*, &c. The vowel in *spear* is anomalous.

§32. *M.E. i*.—The diphthonging of this vowel probably began in the 15th century at latest. The new sound was soon levelled with that of M.E. *oi*, and we find *anynted* in 1430, *defoyled* 'defiled,' *pyson* 'poison,' later in the century. In 17th century we get *gine* 'join,' *byled* for 'boiled,' &c. Pope rhymes *line*—*join*, &c. The normal development of this diphthong was [ai], whether from *i* or *oi*, but the spelling has affected the pronunciation of the latter, so that 'ile' for 'oil,' 'bile' for 'boil,' &c., are now vulgar, though very common in the dialects.

§33. *M.E. ō² (slack=[ɔ])*, cf. §§7 (b), 10.—This vowel, which occurred in *hōm*, *lōp*, *gōt*; *hōpe*, *thrōte*, &c., became [ɔ] after old tense *ō* had become or was about to become [ū], and this sound lasted at any rate till late 18th century. The present diphthongal pronunciation is first noticed by Batchelor, 1809.

§34. *Un-rounding of M.E. ō*.—This was apparently a West-country change. A form *starme*

'storm' occurs in a Wilts text c. 1420. This type of pronunciation is still heard in the West, and in American English. The un-rounded forms are found sporadically in the letters of all classes in London English from 16th century onwards: the vulgar Machlyn (1530) has *Dusset* 'Dorset', *harse* 'horse', *cuffen* 'coffin'; Lady Hungerford 1569 writes *swaen* 'sworn'; and Q. Eliz. has *stap*. Note that Shakespeare rhymes *folly* with *dally* in *R. of Lucr.*, 554-556. The pronunciation became fashionable during the 17th and early 18th centuries, as may be seen from Vanbrugh's burlesque of it in the character of Ld. Foppington. The 17th-century Verney Memoirs have *folly* 'folly,' *sassages*; and Mrs Basire writes *George* 1655. The forms *strap*, *Gad*, survive to-day, and *plat* for *plot* (of ground) occurs in the Authorised Version.

§ 35. *M.E. ð¹ (tense)*.—This developed into something like the present sound already in M.E. (§ 16). Spellings with *ou*, *goud*, *houk*, &c., and with *u*, *gud*, &c., are quite common in the 15th and 16th centuries. We have three groups of words at the present time whose vowels all go back to this M.E. *ō*: *moon*, *spoon*, *rood*, where the new [ū] remains unchanged; *hook*, *book*, *good*, &c., where the vowel has been shortened, perhaps during the last 150 years; *blood*, *month*, *flood*, *glove*, *mother*, &c., where the new vowel was first shortened in the Early Mod. period, and then treated like old *ū* (§ 39, below). This differentiation is apparently the result of dialect mingling in Received Standard. The age of the first shortening was clearly prior to that in which M.E. *ū* was altered, and on this see evidence in § 39. The spellings *fludde*, *bludde*, in 16th century probably represent the early shortened forms, which by this time had undergone a further change in the direction of our present sound in those words.

§ 36. *M.E. and Early Mod. au*; also *M.E. ou*.—This includes words like *law*, *saw*; *cause*, *haunt*, *caught*; and the later group *all*, *stalk*, *tall*, &c. (§ 26); further, *thought*, *daughter*, &c. The process of change to the present sound was probably [au-ou-ū]. M.E. *ou* in *pochte*, *doughter*, &c., was caught up by old *au* at the first stage above indicated. Surrey (in Tottel) spells *tought*, M.E. *taughte*, rhyming with *yverought*, M.E. *wroughte*; and Ld. Buckhurst rhymes *wrought*—*caught*, showing that the two sounds had become identical. The 16th century also saw the simplification of the diphthong, as is shown by such spellings as *also* 1535, *ont* 'aunt', *a nobe* 'an alb' c. 1550. The above is the main source of our present [ɔ] sound.

§ 37. *M.E. ai, ei*.—These two original diphthongs were identical in sound in Late M.E., and = [ai]. The first element was fronted, and then the second was dropped, so that the sound became identical with that from M.E. *ā* and *ē* [ɛ]. Thus the process was [ai-ɛi-ɛ-ɛ]. The sounds were probably united at the [æ] stage in the 15th century, where they are both often written alike—a for old *ai*: *sa*, 'say', *feth* 'faith', M.E. *feith* c. 1442, &c.; and conversely, *ai* for *ā*: *maid* for M.E. *māde* 1421, *snayke* for M.E. *spāke* 1539, and so on. Henceforth the history of *ai* is that of M.E. *ā*, which has already been outlined.

§ 38. *M.E. ā*.—The words *how*, *cow*, *house*, &c., all contained this sound. We have retained the old spelling (explained § 5), but have diphthongised the vowel. Spellings such as *abaught*, M.E. *aboutē*, *saunde*, M.E. *found*, *aur*, M.E. *our*, &c., occur in the Paston Letters of the 15th century, and *sauth*, M.E. *south*, in the Godstow Register of the same century. There is no doubt that a diphthong is intended, but we cannot be sure how far it has gone towards the present sound. The 16th-century orthoëpists describe the diphthong as made up of *o+u*; in 1625 a French writer transcribes *how* as

haow, which must mean something very like our own sound. In any case the starting-point of diphthongisation was earlier than the development of the new *ū* (§ 35), and we have seen that this, for various reasons, must be placed probably not later than the third quarter of the 14th century at latest.

§ 39. *M.E. ū (including Engl. and Fr. u [y])*.—This vowel has undergone un-rounding, and has passed into the characteristic sound heard in *but*, *cut*, *run*, *hunt*, &c. The old sound still survives in some words, after lip-consonants: *put*, *pull*, *bush*, *bull*, &c. At the moment when the un-rounding started there were four classes of words which had all the same *ū* sound: (1) M.E. *ū* in above examples; (2) those containing M.E. [y], written *u*: *bundle*, *thrush*, *cudgel* (§ 19); (3) French words containing Fr. *u*=[y]: *judge*, *public*, *study*, &c.—classes (2) and (3) must have altered their vowel, by retraction, to the *ū* sound; (4) words containing M.E. tense *ō*, which had become the new [ū] and been shortened: *flood*, *glove*, *done*, &c. (§ 35). Thus sounds of four different origins had all become identical, and their common sound underwent in all cases the same change. There are 15th-century spellings which at least suggest that un-rounding has already taken place: *gannes* 'guns,' *sadanly* 'suddenly,' *camyth* 'cometh' (M.E. *cām-*), &c. It does not follow that this implies a sound identical with that of to-day.

§ 40. *M.E. ū (= French ū [y]; and M.E. ēu; eu = [ēu]; iu)*.—These sounds appear to have been all levelled under a single form [jy] in Late M.E. Examples of the several groups are: *ūse*, *dūke*, *dūe*, *issūe*; *knēw*; *hūe*, M.E. *hēu*, pret. 'hewed,' O.E. *hēow*; Bokenam rhymes *greu*, pret. with *vertū*; *sewer* 'sure,' *dewke* 'duke,' *dew* 'due,' *indewer*. In 16th century we find *blue* 'blew,' *nu* 'new,' &c. Opinions differ as to when [jy] developed into the present sound [jū]. The 17th century orthoëpists differ in their statements; many assert that 'long *u*,' as they call it, meaning the sound in *tune*, *duke*, &c., still had the French sound, while others state that the English sound is different from the French. It seems certain that all the above words had the same sound. In 15th century at least the only question is, What was it? How soon did the present sound arise? The fact probably is that some speakers retained [jy] far into the 17th century, while others already pronounced [jū] as at present.

The spelling *youes*= 'use,' vb., which occurs in 1569 (Lady Hungerford), seems to make it certain that that lady pronounced as at present, and the spelling *youst* 'used,' *young* 1647, *youmore* early 18th century, all point in the same direction. On the other hand, to quote an authority not generally cited in this connection, Voltaire in the *Dictionnaire Philosophique*, in the article 'Langage,' says: 'Les Anglais qui ont corrompu toutes les voyelles . . . n'ont point abandonné *u* . . . il disent *vertu* et *true* et non *vertou*, *troue*.' This as clearly points to [y], and Voltaire spoke and wrote English fluently. We thus cannot be sure whether Shakespeare and Milton pronounced *duke*, *dew*, as we do at present, or whether they said [djyk, djy], but we can be sure that both pronunciations were in vogue in the English of their times.

§ 41. THE VOWELS IN UNACCENTED SYLLABLES.—The habit of 'slurring,' shortening, or 'obscuring' vowels in unstressed syllables is not of recent origin. On the contrary it has been characteristic of English speech at every period of its history. To this habit

it is due that an inflexional system of O. E. crumbled almost to nothing in M. E. During the latter period a new series of vowels often appeared in unstressed syllables; some due to new compounds, some to the adoption of foreign words, others again which for some reason had escaped an earlier reduction, experienced the process in the later M. E. period. In many French words of two syllables the accent was formerly on the second syllable; later, according to English habits of speech, the stress was shifted to the first, and the second was shortened or obscured. The following brief list of occasional spellings drawn from documents ranging from the 15th to the 18th century tends to show that the present-day pronunciation of unstressed syllables, or something very like it, must have been established certainly before the end of the 15th century. In some cases the examples are found in each of the four centuries; in others, they have been found in writings from later periods. The earliest available only are given, as a rule, for economy of space.

It will be noted that in some instances, owing to the influence of the traditional spelling, a new pronunciation is now current which is supposed to correspond more exactly to this. The examples are arranged under the different vowels before various consonants. They are mostly, though not always, drawn from private letters and diaries. -*ed*: *beloued* 1420, *wrechid* 1451; -*eth*: -*ith* and *yth* very common in London and other Engl. in 15th century; -*es*: *massis* 1450, *chargis* 1455, *versis* ib.; -*est*, *eldyste* 1450-70, *fairyst* (superl.) 1490; -*en*: *oftyn* 1430, *kechyn* 1451; *el*: *unkyl* 'uncle' 1451, *appyl-tre* 1430; -*less*: *harmys* 1465; -*ness*: *kindnis*, *happinis* Q. Eliz.; -*ess*: *dutchiss* 1705; -*ledge*: *knowliche* 1447; -*et*: *markyt* 1473, *bullis* 1708; -*ac*-, *stomechere* 1478, *stomachers* 1645, *stonick*, *Izic* 1724; -*age* (-*ange*), *messyngere* 1450-70; -*ave*: *St Olafes* (St Olave) 1462, *Olive* 1701; -*age*: *marriges* 1556, *vicarige* 1605, *corige* 'courage' 1641; -*nas*: *cryustynmus* 1550, *crismus* 1634; -*on*: *sesyn* 'season' 1451, *reasyen* 1512, *matten* 1529; -*o*:- *dysabey* 1451; -*of*-, *men a waire* 1531, *tenne a clocke* 1573-80; -*of*: *fagets* 1661, *som't* 1701; French -*ure*: *paster* 'pasture' 1420, *moister* 'moisture' ib., *unscripterlye* Bp. Latimer, *manner* 'manure' 1535, *tortering* Shakespeare 1st fol., *jointer* 'jointure' 1570, *futer* 1664; French -*ure*: *comyned* together 1447, *mysseforten* 1550, *misfortin*, *fortin* 1642, 1645, 1663, &c., *forting* 1663—said also by Tony Lumpkin; French -*uite*: *condytte* 'conduit', *byskitt*, *minite* (a note) 1473-83; French -*u*:- *repetition* 1469, *monimentary*, *miraculous* 1677, *vertuous* 1708; French -*u*:- *newys* (= *nevys*) 1550, *valy* 'value' 1642, *nevie* 1655; -*aw*, *ow*: *felas* 'fellows' 1430, *fellyschyp* 1470-80—Pope rh. *fellow*—*prunella*; -*night*: *senet* 'se'nnight' 1656, *fortnet* 'fortnight' 1654; -*ain*: *certyn* 1447, *certyne* Anne Boleyn, *captin* 1642, *vilin* 1655; -*day*: *Mundy* 1573-80, 1647; *Fridy* 1642. These few examples are enough to show how old are the habits which some now condemn. The examples are nearly all taken from persons of the upper class. A full discussion of the subject and numerous examples will be found in Wyld's *History of Mod. Colloquial Engl.*, ch. vii.

CONSONANT CHANGES IN MODERN PERIOD.—§42. The various modifications of consonantal sounds which can be traced, some from 14th century, some from 15th, fall generally under the following heads: (1) Isolative Changes without loss or addition; (2) Combinative Changes involving neither loss nor addition; (3) Loss of Consonants; (4) Addition of Consonants. The results of some of these processes still survive in ordinary speech, others have disappeared in Received Standard owing to the recent tendency to assimilate pronunciation to the sup-

posed 'correct' forms suggested by the traditional spelling. This tendency is comparatively recent, and far on into the 18th century the best speakers were unaffected by it. There are many other categories of which space forbids mention, and the following are only a few from many examples. The writers of the following nearly all belong to the upper classes, some are well-known authors.

§43. *Isolative Changes without loss or addition.*—(a) M. E. -*gh* becomes *f* (spelling still retained): *thorff* 'through' 1465, *troff* 'trough' 1553; to *laffe* 1553. (b) M. E. -*ht* becomes -*ft*: *unsoffethe* 'unsought' 1450-70 (= [ansoft]), *daughter* rh. after 1604, *dafter* very common in 17th century. (c) Substitution of -*n* for -*ng*: *holdyn*, *drunkyn* 1389; *wrytyn*, noun, 1443, *hangyn*, *walkyn* 1450, *hangyns* 1520; *sytyng*, *rydyn* 1550, *besichen*, Q. Eliz., *seem*, *bein*, *comin* 1642, *shullins* 1657, *disoblegin* 1664, *takin*, *dynyn*-room, *approchin*, *mornin*, *writins*, &c. Lady Wentworth 1705. Pope rhymes *gardens*—*farthings*, and so on. The reaction against this pronunciation seems to have started c. 1830, but has by no means completely triumphed.

§44. *Combinative Changes without loss or addition.*—(a) -*sz*-, *ti*-=[*s*, *tj*] become [*f*], also -*su* [-*sjū*] becomes [*ju*]: *consheus* 1469, *derecsheus* 1470-80, *instrocshens* 1544, *commysshin* 'commission' 1539, *suspsheously* 1649, *mentshoned* 1650, *pashens* 1664, *Prushee* 'Prussia' Lady Wentworth 1705; *ishu* 'issue' Gabr. Harvey's Letters 1573-80. (b) Initial -*su*- becomes 'shu': *sheute* 'suit' 1593, *shur* 'sure' 1642, *shuite* (of clothes) 1653, *ashoure* 'assure' 1653. (c) -*di*- becomes [dʒ]: *surgears* 'soldiers' 1550, *teges* 'tedious' 1647, *contages*, *Injan* 1701, *edjuicate* 1801.

§45. *Loss of Consonants.*—(a) of initial aspirate: *alf* 'half' 1389, *alpeny* ib., *astely* 1463, *ouldre* 'hold' 1503 (Mary, daughter of Hen. VII.); *ede*, *cliff*, *ard*, *elmet* 1550. (b) *swo*- becomes *so*: *sor* 'swoire' 1451, *sord* 'sword' 1593, *sowlen* 'swollen' 1593, *sord*, *solen*, *sorn* given as proper pronunciation for *sword*, &c. 1701; *ku* (qu) become *k*-, *coting*=quoting in *Euphuus*. (c) Loss of *l* before lip and back consonants and some others: *behaf* 'half' 1442, *Fukonbrige* 1465, *Mamsey* 'Malmsey' 1570-80, *stauke* Q. Eliz., *swolne* ih. *bemoan* E. of Surrey in Tottel, *swone* written by Machyn 1550, *shuuld* Elyot's *Governour* 1531 and Gabr. Harvey, *wood* 1665. (d) Loss of *r*. The earliest examples are before -*s*: *wurst* rh. *adust* 1441, *wosted* 1450, *passell* 1470-80, *mossele* c. 1460, *church* rh. *suck* 1528, *skasely* 1544 and 1556, *furst* ih. *dust* E. of Surrey in Tottel, *Fotescue*, *Fottescue* 1635-36, *quater* 'quarter' 1642, *Gath* for *Garth* Lady Wentworth 1705-11, *Dotchester*, *Molbery* 'Marlborough' ib. 18th-century writers affirm that *nurse*, *purse*, are pronounced like 'nuss', 'pus,' &c. (e) Loss of *d* before and after other consonants, medially and finally: *reenly* 'friendly' Hoccleve, *Wensday*, *myssomer* 1450, *Wostrett* 'Wood St.' 1550, *stannestill* 1593, *Lonan* 'London' 1654, *Lunnon* 1757, 1765, 1787, *blын* 'blind' 1389, *husbon* 1440, *my Lor* 1470-80, *rebowne* 1528, *bylne*, *cote harbour* 1550, *friten*, p.p., 1642, *thousan*, *Sunderlin*, *own* 'owned', *Richmon*, &c. Lady Wentworth. (f) Loss of *t* in same positions: *fonstone* 1420, *morgage* 1448, *offen* 'often' Q. Eliz., *wascote* 1593, *Christmas* 1639, *bustling* 1701, *Seynt Johan* pe *baltis* 1389, *nex* 1462, *excep* 1470, *uprigh* 1503, *Egypte* 1550, *respects* 1629, *Papeses* 1655, *pagyn* 'pageant' 1701, *prospeck*, *strick*, *tex* 'text' Lady, and P. Wentworth 1705-11; Pope rhymes *neglects*—*sear*. (g) Loss of *b*: *Lameth* 'Lambeth' Archbp. Cranmer 1534, *tremlyng* 1557, *nimlest* Q. Eliz., *Cammerwell* 1607, to *clyme* 1580.

§46. *Addition of Consonants.*—(a) Of *w* initially before *one* and *ho*:- *won* 'one' 1420, 1426, 1466, 1549,

1593, &c. &c.; *wholle* 'whole,' earlier *hole*, 1420, *whome* 'home' 1442, *wolde* 'old' 1479, *whot* 'hot' ib. and 1550, &c. (b) Addition of consonants finally: *Jaylades* 1420, *lynand* 'linen' 1470, *wyld* 'will' 1449, *synst* 'since,' *downed* 'down' 1528, *varment* 'vermin' 1539, *sermont* ib., *surgiant* 1573-80, *mush-rompe* (*Euphues* 1586), *orphant* 1582, *vilde* 'vile' common in Shakespeare 1st fol., Donne 1h. *vilde*—*child*, *schollards* 1641, *micklemost* 1642, *night-gownd* 1683, Swift rh. ferment—vermin, *sarment* 'sermon,' *laught*, inf., *saft* 'safe,' *lost* of time, *gownds* Lady and P. Wentw. 1711-13.

(For more information on the Consonants see ch. viii. of Wyld's *Colloquial English*.)

ENGLISH INFLEXIONS.—§47. *Definite Article*.—The full inflexion of this in all genders and numbers must have been considerably impaired in most areas, in the spoken language, before the end of the O.E. period. In Midl. by the middle of 12th century the indeclinable *pe* is a word in frequent use in written English. In the more southerly areas the old *per*, gen. and dat. fem. sing., *pen(e)*, acc. sing. m., and *pon*, &c., dat. sing. m., occur as late as the 13th century. The old neut. sing. *pet*, *pat* is used first as the article; but more and more with a demonstrative force as at present. It survives, however, into the Mod. period in the *tone*=*that one*. The old M.E. acc. or dat. survives in *for the nonce*=*for then ones*. In the place name *Atterbury* the dat. fem. survives, =*at per*, whence *atter-bury*. The pl. *pō* is used as late as 15th, and, rarely, as the 16th century. With disuse of the fem. and neut. forms of the article, grammatical gender disappeared and was replaced by natural gender.

§48. *Nouns*.—After the O.E. period, owing to the weakening of *-a*, *-u*, to *-e* in unstressed syllables, and the tendency to level all declensional types under one of two types, the chief questions are what is the poss. sing. and what is the pl. form of nouns. Speaking generally, nouns either form their poss. in *-es*, according to the old chief masc. and neut. type, or, less commonly, in *-e*, which may represent either an old *-a* of a masc. decl., the *-e* of a fem., or, possibly a weakening of *-an*, the old weak gen. In the middle of 12th century *pes cuēnes* 'the queen's' occurs in Midl., but in the south the *-e* poss. occurs fairly often in the 14th century, and, sporadically, much later. In E. Midl. *steore nāme* (13th century) we have presumably a survival of the O.E. weak gen. *steorran* 'star's,' and also in *huerte loue* 'heart's love,' South-west. Chaucer writes *-es* for poss. in all genders, but has occasional *-e* in old fem. *widewe*, *churche*, *ladye*. He has one example of an old *-u* stem—*sune* 'son.' Phrases like *oure lady matins* occur in Caxton, and as late as 1567; throughout the 16th century isolated examples of these fem. poss. are found, and *our Lady Day* last in 1688; *Lady Chapel*, *Lady Day* are the last survivals. The *-s* is omitted after nouns in *-r*, *father*, &c. as late as the end of 16th century—the *father good will*, 1593; after group-combinations—the *bishop of London palles*, 1550; before words beginning with *-s*—the *younge kinge stomache*, 1588; sometimes in other cases, as late as early 18th century—a *parson widdoe*, 1705.

Such groups as the *King of England's daughter*, &c., are thus inflected occasionally already in Late M.E. In the 15th and following centuries these constructions become increasingly frequent. The normal M.E. construction is *pe kinges suster of France*, cf. the *bailiff's daughter of Islington*. This survives in the 16th century, cf. Lord Berners's *the kynges daughter of Englande*. Where we now say *King Stephen's brother*, &c. the M.E. construction was *pe kinges brother Stephnes*. In 1460 we find the *Lordys wyffe Newyle*, the noun in apposition not being inflected. During the 16th century quite long groups take the inflexion on the last

word of the group—e.g. *our holye father of Romes eares* (Bishop Latimer).

§49. *Plural of Nouns*.—The commonest type in O.E. is the masc. class, which has nom. and acc. pl. in *-as*. This becomes *-es* in M.E., and is by far the commonest type, being extended to most other classes. The only type which at all competes with it in M.E., and that only in some areas of the South, is that derived from the O.E. weak decl. which has *-an* in nom. and acc. pl., M.E. *-en*. This suffix is found, especially in Kentish, attached to old strong (*-as*) nouns: *applen*, *honden*, *dēden* 'deeds,' *bruggen* 'bridges,' as well as the old weak words—*hunen* 'hunters,' *herten* 'hearts,' &c. In Early Mod. Engl. occasional weak pls. are used by good writers—*All soullen college* 1535, *Alhalowentydc* 1483, *Alhalonday* 1567, *housyn* 'houses' (Ascham), *Peason* (Gabriel Harvey), &c. In Kent. texts of M.E. the old weak gen. pl. *-ena* survives occasionally as *-ene*—*kingene*, &c.

Such invariable plurals as *deer*, *sheep*, are survivals of old long-syllabled neuters, which have no suffix in nom. and acc. in O.E. The type still survived in 15th and 16th century English to a far greater extent than at present. Words expressing weight, distance, measure and number, and words used collectively are the chief words affected, but there are others as well, which are more truly survivals of the old type. Of the former—*three thousand pounde* (Bishop Latimer), *three hundred thousand pound*, *an foote thyke* (Life of Wolsey), *2 yeere* (Verney Mem. 1641), *iij fethem* (Gregory, 1460), *ij lambe* 1533, to *bring forth apple* (*Euphues* 1586); of the latter—*all thinge* (Lord Berners), *I trust I shall receve your thanke* (Q. Eliz.).

§50. Of minor classes the mutation-pls., of which *teeth*, *geese*, *lice*, *mice*, &c. are examples, may be mentioned. Originally these were more numerous, and included words of all genders. O.E. *bē* 'books' survives as *bēch* in a 12th-century Kent. text; *geet* O.E. *gāt* 'goats,' and *kēne*, a South-eastern form for *kīne* 'cows,' are found in Caxton.

§51. *Irregular Plurals*.—*Children* is from M.E. *childre*, O.E. *childru*, with the additional weak pl. suffix; *brethren* has both mutation and the weak suffix; in Early Mod. we get this form, also *brotheryn* (1480). In M.E. all the relationship words except father often occur with *-en* in the pl.: *sustren*, *modren*, *dowzren*, &c. On the analogy of *children* and *ēren* 'eggs,' O.E. *ēgru* with *-en* added, we get also *lambren* 'lamb's,' by the side of normal *lambre*, and *calfren* by the side of *calfre* 'calves.'

§52. *Survival of Old Datives*.—The forms *meadow*, *leasowe*, are old datives; O.E. *mædwe*, *læswe*; M.E. *medowe*, *lesowe*, &c.; *bury* in dat. from O.E. *byrig*, nom. *burg*, which gives us *borough*.

§53. *Adjectives*.—In O.E. adjectives have two types of declension, the weak, which is used after the article and which resembles the *-n*-declension of nouns, and the strong, which is used in other cases. The characteristic suffixes of the str. adj. are those of the pers. prons.—*-ne* acc. sing. masc.; *-re*, dat. sing. fem.; *-ra*, gen. pl. In M.E. the weak declen. disappears after the end of the 12th century, unless indeed the final *-e*, commonly used as an attributive suffix in the 14th century as the sole inflexion, without deduction of gender, number, or case, be a weakening of *-an*. The typical strong adjectival endings survive sporadically in the South as late as the 14th century, but on the whole they are rarities after the 12th century. A few cases of *-ne* occur in Worcs. in the 13th century, and rather more in the South and in Kent. A dat. sing. *godere* appears in the S.W. Midl. text of Ancrén Riwe (early 13th); as a gen. pl. *-re* is rather commoner in the 13th century both in E. Midl. and in the South. Even Chaucer still has

such phrases as *your all cost*, and fossils like *alderbest*, where *alder*=O.E. *altra* 'all' are used by him, while a belated *God our aller Creatour* ('of us all') survives in the 15th century (Letter of Richard III. to James III. of Scotland).

§ 54. A curious usage, derived from French, is the addition of the pl. suffix *-s* to adjectives. This is found occasionally in Chaucer when the adj. is used attributively and stands after the noun—*places delitable, goodes temporels*; it is rarer when the adjective precedes the noun—in the *sovereyns devynes substances*, or when the adj. is used predicatively—*romances that ben royales*. In the 15th and 16th centuries these forms are occasionally used in technical phrases—*Lordes spiritualz and temporelz, lettres missives*, &c.; still more remarkable are such constructions as *demures and wise sustris*, &c. (15th century).

§ 55. *Comparison of Adjectives*.—The suffixes *-er*, *-est*, are derived from O.E.; they may represent Prim. O.E. *-ir*, *-is*, or *-or*, *-ost*. In the former case they mutate the vowel of the adj. The forms *eldra* 'elder', *eldest*, *streng*, *strengest*, *lengra*, *lengest*, from *ald*, M.E. *old*, *ströng*, *lōng*, are among the most frequent mutated comparatives and superlatives. *Lenger*, *strenger*, *lengest*, *strengest* are used far into the 16th century; *elder*, *eldest* have long had a specialised meaning, but *elder* is still used by Lily and Spenser, and even by Congreve, as late as 1700 as the ordinary comp. of *old*. The use of *more*, *most* with adjectives which have the comp. and superl. suffixes is fairly frequent in the 15th and 16th centuries. Caxton has *more gretter*; Latimer, *more diligenter*; Caxton, *most strengest*; Lord Berners, *moost outrageous people*, &c. So correct a writer as Lily uses the form *badder* instead of *worse*.

§ 56. *Adverbs*.—These are formed in O.E. (a) by the addition of *-e* (Instr.), *wide*, 'widely'; (b) by addition of *-lice* 'like', *sōþlice* 'truly'; (c) *-unga*, *-lunga*, *-linga*, *eallunga* 'altogether', *grundlunga*, *grundlunga* 'to the foundations'; (d) *-mælum*, *styccemælum* 'piecemeal', &c. From (b) is derived the commonest adverbial suffix, *-ly*; from (c) *darkling* 'in the dark', *heallong*, &c. Further, the gen. and dat. of nouns or adjectives in O.E. are often used adverbially—*ealles* 'completely', *dæg* 'by day', and, on the analogy of this, *nihtes*, which corresponds to *o' nights*, where *o'* stands for M.E. *on* 'in,' and is here redundant; *micelum* 'very' (dat. sing.), *hwitum* 'at times' (dat. pl.), whence with altered meaning 'whilom'; *seldom* is another of this class.

Once, *twice*, *thrice*, M.E. *ānes*, *twies*, *pries*, *always*, *nowadays*, are all old genitives. The last resembles the formation of *o' nights* (a from *on*). It is at earliest a M.E. formation, since in O.E. *on* would take a dat. after it here.

PERSONAL PRONOUNS.—§ 57. *Singular, First Person*.—O.E. *ic*, weakened to *i* in unstressed syllables in M.E. which gradually becomes the prevailing form, except in S.W., where it survived far into the 19th century. Chaucer still uses *ich* occasionally, but generally *i*. Acc. and dat. *mē* call for no remark, as they survive with the normal change of vowel. Generally *mīn* is used as a real genitive in O.E., and occurs after verbs governing gen.—*God helpe mīn* 'God help me', &c. It is also used as a poss. adj., and is inflected like other strong adjectives. The inflexions *mīnne*, *mīnre* (or *mīre*) are still found in 13th century. In M.E. *mī* 'my' occurs before consonants, *mīn* before vowels.

§ 58. *Second Person*.—O.E. *þu*, *þē(c)*, *þīn* survive in M.E. and later with the normal vowel changes.

§ 59. *Third Person Masculine*.—O.E. *hē*, *hīne*, *hīm*, *his*. The nom. dat. gen. (poss.) survive to present day. Acc. *hīne* survives in S.E. Midl., and is used

still more frequently in the South during the 13th century. Gradually *him* is more and more used indifferently for acc. and dat. Many rustic dialects still retain *hine* in form of *ʼin* [ən], used perhaps more of things than of persons.

§ 60. *Third Person Feminine*.—O.E. *heo*, acc. *hie*, *hi*, gen. dat. *here*. Except in Nth. and occasionally in E. Midl. the old nom. survives in M.E. till the 14th century, and in the W. much longer. Peterb. Chron. (1154) has already *sē* 'she'; the earliest Nthn. texts have *swē*, *schē*, &c. In W. Midl. (14th century) *schē*, *shē* are used alongside of old *huc* (*hēo*) and *zhē* *Schē*, &c. early becomes the regular form in London English. As late as 1420 the Wilts S. Editha has *hē*, *hec* as the only forms. The M.E. acc. dat. and gen. are normally *here*, *hir*, *her*, *her*. The weak form a 'he' is used by non-dialectal writers as late as 17th century.

§ 61. *Third Person Neuter*.—O.E. nom. and acc. *hit*, other cases as in masc. *Hit*, together with all other pronouns in *h*, often loses the aspirate already in the 13th century. Thus *it*, as well as *e*, *im*, is all occur, in unstressed positions, in 13th century. On the other hand, *hit* is frequently written by Q. Eliz., and this is still common in Scots dialects. The new poss. *its* is not recorded till late in 16th century.

PLURAL FORMS OF PRONOUNS.—§ 62. *Third Person*.—*They*, *their*, *them* are Scandinavian forms, compared with O.E. *hie*, *heora*, *heon* (*him*). In the nom. all Sthn. texts write various *h*-forms, *heo* and more frequently *hē* down to and during 14th century. The Wilts S. Editha still has *hec*, *hoc* in 1420. The London poems of 1327 still use *hii*, but all later texts appear to use *pei*, *thei* only. The E. Midl., with the exception of Oim (1200), have *hī*, *hē* down to end of 13th century; after 1300 *pe* appears, at first occasionally, and then as the usual or only form. W. Midl. has *hii*, *heo*, and *pei* in 1350, thereafter apparently only *pey*, *thai*. The Nthn. texts have only the *th*-forms in M.E. Some Sthn. texts have *ha*, *a* as unstressed forms.

§ 63. In dat. and poss. the *th*-forms are later and slower of introduction than in nom. All Sthn. and Midl. texts, well into the 15th century, have *hem* and *here* as the usual forms; *þeȝm* (= *them*) is found by the side of *hem*, and *þeȝre* by side of *heore* in Oim, and during 14th century *them*, *theim*, *peyr*, &c. occur occasionally by the side of more usual *h*-forms. Nthn. texts always have the Scand. *th*-forms. The London documents invariably write *hem*, *her(e)* down to the end of the 14th century, and even Caxton still uses the *h*-forms more frequently than the *th*-. The weak form *em* is used in the third quarter of the 15th century. After the beginning of the 16th century the *th*-forms, *their*, *them*, are practically universal; and the others, during this century, may be regarded as rare curiosities. *Her* is found, however, in *Nut Brown Maid* (1500) in Surrey's poems (once), a few times in the early folios and quartos of Shakespeare. The latest known colloquial use of *her* is in Maclyn's Diary. As regards *hem*, this survives to this day in the form 'em (the apostrophe indicating the supposed derivation from *them*). 'Hem is written in Ben Jonson's *Every Man in his Humour* (1598), and *-am* in Chapman's *All Fools* (1605). During the later 17th and the greater part of the 18th century 'em is used very frequently in comedies, private letters, and in serious literary works. The forms *his*, *us*, *hes*, *es* are used as acc. = 'them' down to first half of 14th century in Kent, and frequently during the 13th century in the S.E. Midl.

§ 64. *Second Person Plural*.—O.E. noun *ȝē*, acc. and dat. *ēow*, gen. *ēower*. The M.E. *you*, *ȝou*, *youre*, *ȝoure*, &c., whence Mod. *you*, *your*, owe their initial consonant to the old nom. M.E. *ȝē*, the earliest

M.E. *ou* soon gives place to forms with *y*, &c. In 14th century *ye*, *you* are already used as mark of respect in addressing a single person, and the distinction between this and the more familiar *þu*, *þe* is preserved into 16th century. Down to the middle of the 16th century writers generally distinguish between nom. *ye* and acc. dat. *you*. After that both forms are used indifferently for the nom.; Q. Eliz. seems to use only *you* for all cases. *Ye*, though more rarely, is occasionally used as an oblique case. *You* and *ye* are sometimes both used as nom. in the same sentence in 16th century for the sake of variety. *Ye* survives in *how d'ye do* [*haudulū*], and as the familiar and now obsolescent *thank ye* [*þenki*]. It should be noted that present-day *you*, *your* [*jū*, *jū*] are derived from the M.E. unstressed and shortened forms *yū*, *yūre*. Chaucer still uses *you*, *youres*, with long vowel rhyming with *thou* 'thou,' and *oures* 'ours.' These forms have been lost.

§ 65. *First Person Plural*.—O.E. *wē*, dat. acc. *ūs*, gen. *īre*, M.E. *wē*, *ous*, *us*, *oure*, correspond exactly to the present-day forms, except that *us* [as] is derived from the M.E. unstressed form *ūs*, the stressed *ous* having been lost.

§ 66. *VERBS*.—Verbs in English, as in other Germanic languages, are distinguished into strong and weak. The former have a change of vowel in the pret. and p.p., but no suffix with *-de*, *-d*. The latter form the pret. in O.E. with the suffix *-ede* or *-ode*, and the p.p. with *ed* or *od*.

§ 67. *Personal Endings*.—Pres. indic. sing. O.E. *e*, *-est*, *-(e)þ*; pl. *-ap* for all pers. In M.E. the sing. remains on the whole unchanged in Sth. and in Midl.; the pl. has *-ap* in Sth., *-e(n)* in Midl. In London English the third sing. usually has *-eth* almost exclusively till far into the 16th century, though *-es* appears occasionally. During the 16th century *-es* becomes increasingly common, until by the beginning of the 17th it is gradually becoming the prevailing form. The *-eth* suffix, however, survives as the only form in the Liturgy and in the Authorised Version of the Bible. It persists also in occasional use even in private letters during a great part of the 17th century. The pres. pl. is usually *-e* or *-en*, after the Midl. type in Chaucer, and *-en*, *-yn* are found frequently till the end of the 15th century. This ending is originally due to the analogy of the subj. or to the strong pret. pl. The Sthn. ending *-eth* also occurs occasionally in London English of 14th and 15th centuries, and quite sporadically in the writings of persons who do not otherwise employ Regional dialect forms in the 16th and 17th centuries. It is not uncommon to find pres. pls. in *-es* even in literary works and in private letters of the later 16th and 17th centuries. This form is probably due to the analogy of the sing. As regards the *-es* of the pres. sing. in London and literary English, this has been held to be due to Nthn. influence. It is true that *-es*, *-is*, *-s* are the typical Nthn. endings from the Late O.E. period onwards, but it is difficult to show that the Nthn. dialect exerted direct or even indirect influence on London English. The E. Midl. dialects, through which the influence might have come generally, has *-eth*, *-yth*, almost as late as London itself. On the other hand, an occasional *-es* is found in the Sthn. dialects in the 15th century, when Nthn. influence is out of the question. It therefore seems more probable that the *-s* suffix in London and the Sth. is due to the analogy of the extremely frequent *is*.

§ 68. *Infinitive*.—In O.E. *-an*, *-ian* (Prim. O.E. *-jan* and *-ōjan* respectively); M.E. *-en*, *-ien*, *-e*, *-ie*, &c. In the London dialect of the 14th century practically the only type is that in *-en*, which often drops the *-n*. In the 15th century *-e* is usual, but *-en* occurs occasionally—e.g. in Caxton, but more frequently in

more or less provincial writers. An exceptionally late example is found in Sackville: *I can accusen none*. The old *-jan* suffix, which occurs principally in weak verbs, mutates the root-vowel (cf. § 3, 7), hence *tēcan* 'teach,' from *tāh-jan*, &c.

§ 69. *Present Participle*.—O.E. *-ende*, M.E. *-end(e)* Midl., *-inde* Sthn., *-auil(e)* Nthn. The early London dialect has both the Sthn. and Midl. forms, but by Chaucer's time the new form *-ing* is alone used. This is derived from the verbal nouns *lern-ing*, &c. Already in late 14th century the *-ing* interchanges with *-in*, *-yn*, and it seems probable that the normal pronunciation of this ending, among educated people, at least to the end of the first third of 19th century, was almost universally *-in*. Then a tendency arose to restore *-ing*, which rapidly gained ground, though *-in* survives to the present day among wide circles of speakers of every degree of education, though less perhaps among middle-class speakers than elsewhere.

§ 70. *Past Tense and Past Participle in Weak Verbs*.—The old suffixes *-ede*, earlier *-ada*, and *-ode*, earlier *-ōda*, are kept distinct in Early O.E., but later tend to be confused, and the same is true of the p.p. endings *-ed*, *-od*. The suffixes *-ida*, *-ud* mutate the vowel of the root if this is susceptible of the change. Thus original **fōd-ida* 'fed' produces in O.E. *fēd-de*, the *-i-* being lost after having wrought the change; the p of this verb is *ge-fēd-(e)d*. The suffixes are sometimes added to the root without any intervening vowel, as in O.E. *tāh-te* 'taught,' *sōhte* 'sought.' Here the root-vowels are unmutated, since neither *-i-* nor *-j-*, as in the pres. and inf., was present to produce the vowel change. The difference between the consonants in the inf. and pret. of these and other verbs ending originally in *t*, O.E. *ð*, is due to the early pre-O.E. change of *-kt-* to *-ht-*, **sōk-ta* becomes **sōh-ta*, &c. The form *sōk-ta*, from earlier *sōk-da*, is due to the unvoicing of the *-d-* of the suffix after *k*.

§ 71. *Strong Verbs*.—The verbs which, instead of the suffixes *-ede*, *-ed*, &c., have merely a change in the vowel of the root to distinguish pres. and inf. from the pret. and p.p., fall into seven classes in O.E. They must be studied in special works, but a few points may be noted here. The types of the pres., the pret. sing., the pret. pl., are in some cases all distinct. Thus *bræcan* 'break,' pret. sing. *bræc*, pret. pl. *bræcon*, p.p. *broc-en*, &c. In M.E. a simplification gradually occurs, by abolishing distinction between sing. and pl. in pret. and either using the sing. type for both sing. and pl., or the p.p. type for both numbers of the pret. as well. In Chaucer the variety in the strong verbs is still very largely preserved; thus *finde* 'find,' pret. sing. *fōnd*, pret. pl. *funden*, p.p. *funden*, O.E. *fīndan*, *fānd*, *fūndon*, *funden*. M.E. gets rid of such differences as are seen in O.E. *ēōsan* 'choose,' *lēas*, *curon*, *coren*, by eliminating the consonantal differences in the pret. and p.p., on the analogy of the type of inf. and pres.; thus inf. *chēsen*, pres. *chēse*, pret. *chēs*, *chēse(n)* or *chōse(n)*, p.p. *chōsen*. Some verbs, e.g. those of the 'write' class, show only such differences in M.E. compared with O.E. as consist in normal change in the vowels: O.E. and M.E. *writē*; pret. O.E. *wrāt*, M.E. *wrōt*; p.p. *writen* in O. and M.E. The pret. pl. type, O.E. *writen*, survives unchanged in M.E., but the tendency is to use either *wrote* or *writ* for both sing. and pl. *Bite* belongs to the same class, but has long lost the pret. *bote* (O.E. *bāt*), which survived in 15th century. *Bit* is due to the p.p. type. Strong verbs may pass from their original class into another. Thus our p.p. *spoken* is formed on the analogy of *broken*, the O.E. being *sprecen*. As a matter of fact, the two verbs agree entirely in their vowels in O.E. except in the p.p. The pret. *spoke* is formed on the analogy of the new p.p.

The vagaries of the strong verbs, owing to the various possibilities arising from analogy and confusion of classes, have been so numerous since Early M.E. right down to the 17th century, that the history of each class, and indeed of each verb, must be specially studied. A single point of resemblance between two classes may produce a new form; thus, doubtless, the common *drave*, instead of *drove* in the 16th century, arose from the analogy of *gave*, the point in common between the two verbs being *driven*, *given* in p.p.

§ 72. In O.E. the p.p. of uncompound verbs usually has the prefix *ge-*. In M.E. this, though lost farther Nth., survives as *y-*, *i-* in the Sth. and S. Midl. It remains in London English into the early 16th century, but exists now only in such archaic forms as *yolept* 'called.'

ENGLISH DIALECTS.—*The Present Day*.—§ 73. At the present time the innumerable varieties of English speech may be generally grouped as *Regional Dialects* on the one hand, and *Class Dialects* on the other. The former are associated with particular geographical areas, the latter with social divisions. Among Class Dialects we must place what is often called *Standard Spoken English*, and also the various vulgar deviations from this which are heard among uncultivated speakers. It is proposed to call the best and most refined form of Standard English, as heard among the upper ranks of society, *Received Standard*, and the vulgar variants, *Modified Standard*. In origin, Received Standard was that variety of S.E. Midl. spoken in London, and more particularly at the Court. This was the dialect in which Chaucer and Caxton wrote, and it gradually became, not only the sole form of English, in which, with a few notable exceptions, literary works were composed and printed, but also, though this was a slower process, the recognised medium of speech, used by the upper classes and by persons of education, all over the country. As this form of English spread to remote areas, and among different social grades, who abandoned for it the use of their native Regional Dialects, the standard underwent modifications. It was influenced partly by the Regional speech, partly by the different speech habits which arose among the various sections of society. Thus side by side with a practically uniform upper class English (Received Standard) there developed a host of variants, often tinged with provincialisms and vulgarisms, which we call *Modified Standard*.

Turning to the Regional Dialects pure and simple, which are heard in their least corrupted form among the populations of rural areas, we find a great wealth of variety, and it should be remembered that the principal features of the several Regional Dialects are not, as some suppose, the result of faulty and imperfect attempts to reproduce Received Standard, but are traditional, in many cases of considerable antiquity, and that they have grown up and been handed down quite independently of the historical development of Received Standard and of the main stream of literary English.

English dialects, like other more important divisions of speech, are classified according to certain features which they possess in common, the existence of which in several languages or dialects is believed to show closeness of genealogical relationship and community of origin.

§ 74. These features may consist in (a) phonological character, (b) peculiarities of accent and grammatical usage, (c) the nature of the vocabulary. For the present purpose the above order is probably that of relative importance. By phonological agreement is meant the identical treatment of the same original sound. This kind of agreement is closer the farther back we trace the history of

dialects, though in later times fresh differentiation may occur. Thus if at the present day one dialect pronounces *stone* as 'steen' [stɪn] and another as 'stane' [stæn], it is evident that in spite of the present difference they both go back to a common type in which O.E. *ā* was fronted, and belong to a large group of dialects which shared this feature, and not to another group which rounded *ā* to *ō*, to which Sthn. English belongs, and which pronounces O.E. *stān* as [stɔn, stoun, stœn], &c.

The least satisfactory basis for classification is vocabulary, since words, especially in the Modern period, pass easily from one district to another, through the medium of books and newspapers as readily as by word of mouth.

The classification of Modern English dialects presents extraordinary difficulties, and Wright (*Dialect Gr.*, 1905), while adopting in the main the division proposed by Ellis (*Early English Pronunciation*, pt. v., 1889), is careful to point out how difficult is the task of classification, and how unsatisfactory the results of the most careful attempt, though based upon a vast collection of facts.

§ 75. The truth is that at the present time many of the old landmarks have perished, and the old boundaries which once divided one type of English from another have been broken down. Owing to various social and political upheavals, owing also to the shifting, in many areas, of the population into widely distant parts of the country, the Regional dialects now present, in many respects, a most confused picture. Not only have some dialect forms passed far beyond their original home, but the problem is further complicated by the continuous influence of Standard English, which has been steadily exerted for centuries, both directly through the squire, the parson, and the schoolmaster, and indirectly through printed literature. Among the problems of the future, as yet hardly approached, is the task of disentangling the accretions (a) from other neighbouring or remote Regional dialects, and (b) those from various forms of spoken Standard, which have become almost inextricably intermingled with the fibre of every Regional dialect during the last three centuries at least. This can only be done by tracing the history of each modern dialect back through the intervening centuries to the nearest M.E. type of which a record survives. At the same time a comparative survey must be undertaken of geographically related groups of dialects as they now exist, with a view to discovering when and along what lines the differentiation took place of each from an earlier common ancestral type. In this way we may hope to discover, first of all, what in a given dialect is really old and original, and what is new and derived from external sources; then, but not before, it may be possible to obtain a real genealogical classification of the dialects, based upon their old and historic character, and not confused and clouded by the presence of recent and alien forms.

§ 76. Wright's classification of the existing dialects, giving his main groups and omitting the numerous subdivisions of each, is as follows:

1. *The Scotch Dialects* (of those areas where Nthn. English and not Gaelic is spoken). *N.E.*—The English spoken in the N. of Ireland has much in common with Scots.

2. *Northern English*, including all the Northern counties, the N. and E. Ridings, part of the W. Riding of Yorks., and N. Lancs.

3. *The Midland Division*, which includes S.W. and S. Yorks., Mid. and S. Lancs., right across the country from Chesh. to Notts, and including Lincs.; from Flint, Denbighshire, N.E. Shropsh. to Leic., including also N. Warwics. and N. Wores.

4. *The Eastern Division*, which includes Rutl., the greater part of Nthants., but excluding S. Nthants., Cambr., Norf., Suff., Essex, Beds, Bucks, Herts, and Middlesex.

5. *Western Division, N. and S.—Western (N.)* includes the greater part of Shropsh., a small portion of Montgom. *Western (S.)* includes E. Mon., nearly all Heref., greater portion of Radn., E. Breck., and a narrow slip of Shropsh.

6. *Southern Division* includes S.W. and S. Pembr., parts of Glam., S. Warwcs., S.W. Nthants., E. Heref., Worcs. (including N. Worcs.), Glos., Oxf., and the whole of the rest of the southern areas from E. to W. not already enumerated.

In dealing with his material, however, so as to show the distribution of the various features, Professor Wright finds it convenient to depart considerably from the classification, and to speak of Nth. Country, E. Country, W. Country, &c., of N. and S. Midl., and so on. It is noteworthy that in this more general grouping he puts the dialects of Glos., Oxf., and Bucks into S. Midl.

These attempts at classification are tentative rather than final, and it is probable that with a proper historical and comparative treatment of the existing dialects we shall get a very different grouping. Much of the work on Modern dialects so far is chiefly descriptive and statistical. Very little has been done in connecting the existing forms with their ancestral M.E. types, and the history between the M.E. period and the present day is almost a blank.

§77. *The Older Dialectal Divisions.*—Our knowledge of the precise areas in which many of the literary remains of O. and M.E. were written is at present far less minute than could be desired. Thus the classification usually accepted for the dialects of O.E. is at present of a very general character, and that adopted for the M.E. period, though rather more specific, is still very elementary. Thus for O.E. we distinguish a *Northern* type, a *Mercian* or *W. Midl.* type, *West Saxon*, which includes the speech over a large area from Hants to Devonshire, the variants of which we cannot yet assign with certainty to particular regions within this area, an intermediate type sometimes loosely referred to as a *Saxon Patois* which is exhibited in the Blickling Homilies and in some other homilies and glosses, and which belongs probably to the S.W. Midl. of Worcestershire. Finally, we have examples of a *Kentish* type, preserved chiefly in charters, and, in its later forms, in some glosses and hymns, and a metrical Psalm.

We possess also a 9th-century charter in the dialect of *E. Surrey*, a form of English which closely resembles the Kentish type. Of Eastern O.E. we know next to nothing; the only E. Anglian documents so far available are two Suffolk charters of the late 10th and early 11th centuries.

§78. In M.E. we have at once a greater variety of dialect types preserved, and are more fortunate in being able to allocate a certain number of texts to definite areas. It is usual to adopt the following general classification of M.E. dialects: *Northern English*, including the English of Scotland, which in its earliest forms has not yet been clearly distinguished from Nthn. English; *Midland*, which we are able to divide into N.E. and N.W. Midland, S.E. and S.W. Midl. We are hardly yet in a position to distinguish the *Central Midl.* of Staffs., Derbysh., Leic., N. Worcs., and Warwick. In the *Southern* area we distinguish *S. Western*, *S. Eastern*, which includes Kent, while we have apparently a border region in Surrey, which partakes of the characteristics of East and West, an area which is clearly distinguishable from Hants on the one hand and Kent on the other, although it has some of the features of both.

§79. Another more important meeting-place of dialect types in the M.E. period is London. The dialect of the metropolis, at any rate in the 14th century, partakes of the character of the Sthn. (Saxon) type of Middlesex, of the S.E. Midl., and of Sth. Eastern. The latter elements are generally considered as Kentish, but it is more probable that they passed into London speech from Essex, which region was almost certainly the main channel through which S.E. Midl. features came. The features which the London dialect shares with the Sthn. dialects are most probably indigenous to Middlesex, and these are the predominant features in London documents for many centuries. The London dialect was formerly regarded, and spoken of, as a *mixed dialect*, which, owing to its geographical position and to the social and political conditions prevailing in the capital, had received many of its characteristics from without, through the influx of persons from various parts of the country. With the increase of our knowledge of the M.E. dialects, however, and the consequent widening of our views, it is becoming more and more probable that we should rather regard the London dialect as a unity, showing, if it is true, some features which are characteristic of one area, and others which are found elsewhere, but a genuine product of the rather wide area over which it was spoken—that is to say, we can no longer accept the theory of 'mixture' quite in the crude way in which it was formerly stated. It is one thing to assume that a dialect feature has been introduced directly by a group of strangers, from E. Anglia, say, and that it has gradually been accepted and made current in Middlesex; it is quite another to believe that a particular tendency of change, or a specific type of speech, has gradually percolated through the population of an area, although its starting-point may have been a region more or less remote from some of the districts in which it is subsequently found. It appears more and more reasonable to distrust the older view of hard-and-fast limits for dialects, each, so to speak, with a ring-fence round it which presented an impassable boundary to the gradual spread of a speech-character from remoter areas, a boundary which required to be taken at a single bound, if crossed at all, by a specific immigration of speakers from without.

§80. It seems more in accordance with facts to refuse credence to the theory of rigidly fixed speech areas, shut off from the influence of immediately surrounding areas, and to regard dialects rather as shading and melting almost imperceptibly one into the other, just as geographical areas dovetail one into the other. Rivers are often regarded as forming natural barriers, and as important factors in isolating from each other the communities living on opposite sides. It is quite certain that rivers may, and often do, play such a part. On the other hand, it is equally certain that they may also serve as lines of communication, and that the traffic to and fro across the stream may be lively and continuous.

§81. In classifying English dialects in the earlier periods, regard must be had, less than in the past, to the occurrence or absence of *isolated* features, and more to the characteristic *group* of features exhibited by the texts of the various areas. Thus, formerly, whenever *ð* was found in a M.E. text for Early O.E. *þ* (cf. §§18; 19), as in *cende* 'nature,' &c., O.E. *gēcýnd*, that text was assumed either to be Kentish, or to show the influence of Kentish dialect whether in the author or the scribe. It is now recognised that this particular feature existed over a wide area, in dialects quite remote from, and unconnected with, that of Kent, in those of areas as far away as S. Linc. and Norf., for instance. The

occurrence of *ð* for earlier *ȝ* can help us very little by itself in determining and localising minutely the dialect of a text, beyond ruling out a wide western area in the South and Midlands. We have to inquire with what other features, phonological and inflexional, this particular characteristic is associated. According to the answer to this question, we might place the origin of a given text in Surrey, or Middlesex, or Essex, in Suffolk, Norfolk, Cambridgeshire, or Lincoln.

§ 82. If the characteristic phonological and inflexional features of the London dialect in the 11th century are enumerated, it appears that there is not one which is not found in many other dialects of the same period. What is peculiarly characteristic, on the other hand, is the combination, the grouping, the association, of just such and such features together in the same dialect. It is this *characteristic combination* which is typical of London speech, and which does not occur outside a comparatively restricted area.

It was sometimes forgotten, from the older, rather narrow standpoint, that dialectal conditions do not remain the same in all parts of a wide area. Over such a comparatively vast region as that which may properly be called West Midland, we should expect to find in M.E. a not inconsiderable differentiation. Nor are we disappointed. But having decided that a given text was of W. Midl. origin, students were sometimes disconcerted to discover in it certain features which were commonly held to belong to the South. For instance, the ending *-eþ*, *-eth* in the pres. indic. pl. of verbs is undoubtedly a feature of Sthn. dialects. If this ending appears in a text which on other grounds had been assigned to the Midland area, how is it to be explained? Must we assume that the author, if a Midlander, had lived in the South and had learnt to use this form, or that he was really a Southerner who retained this feature of his native speech, although writing for the moment in a Midl. dialect? Again, 'was he the victim of a Sthn. scribe, who copied his text accurately on the whole, but who betrayed himself by writing *-eþ*, where a genuine Midlander would have written *-en* or *-un*?

§ 83. Any one of these explanations is legitimate and possible, but they do not exhaust the possibilities. The question arises, Was there not perhaps an area in the W. Midl. where *-eþ* was the normal dialect form, and might it not be associated with other features which every student would agree are typical Midl. forms? This question cannot be answered with certainty until the regional distribution of the *-eþ* plurals is precisely known. An important line of investigation then, at the present time, is the exact distribution of typical dialect features. The more tests we are able to apply, the more possible it becomes to narrow down the area within which a given text must have been written. A real difficulty exists in the elimination of features foreign to the original dialect in which a text was written, features imported into it in one of the ways suggested above. How can it be ascertained what is really an alien element introduced from without? This is the great problem that is for ever arising in the study of M.E. dialects, and it can only be solved by patient investigation of every available source of information, and by comparing text with text as minutely as possible. It is precisely in attempting to settle the question of possible scribal or other influence on the dialect of a given text that the importance of applying as many combined tests as possible is exhibited. If a particular grouping or combination of features can be shown to exist not merely in a single text, but in several, written by different scribes, then it may be taken as certain that that particular combination of dialect features is characteristic of the

genuine dialect of a definite area, and that the texts in question are all written in this dialect. It is inconceivable that several scribes writing independently, and perhaps at different periods, should all hit upon precisely the same way of corrupting the original dialect. For instance, on grounds which appear from the application of the above method, it has been claimed that the Jesus text of the *Owl and Nightingale*, as we have it, is written in the genuine dialect of W. Surrey of later 13th century. There are certain features which, appearing in the same text, were formerly supposed to be discrepant, that is, some of them were thought to be imported by the scribe. It turns out, however, (a) that precisely the same combination of features is shown in a Surrey chartulary written at about the same date as the MS. of the *Owl and Nightingale*; (b) that several phonological features in the poem which were supposed to be impossible in the Surrey dialect are found not only in the chartulary, but also in forms of Surrey place-names from various sources, written down before, and after, as well as at the same period, as that in which the MS. of the poem was written. Future investigation must lie in the direction of wide yet minute comparative surveys of the features of the dialects of every area for which evidence is available in M.E. For the main tests of dialect see §§ 85-97.

§ 84. But if nearly everything is still to be done for the history of English dialects down to the end of the 14th century, still more, if possible, remains to be accomplished in relating the M.E. dialect types to those Regional dialects which still survive. The gap between M.E. and the Mod. period has to be bridged. It is only quite recently that the beginnings of a detailed knowledge have been acquired of the history of *Received Standard* (spoken) English during the 16th, 17th, and early 18th centuries. The practice of the first systematic writers on English dialects was to start with O.E. (often with W. Sax.) and to pass straight thence to the present-day local dialect, thus ignoring the intervening nine hundred years. The result was that no problem was solved, none of the vital questions which we should now ask were stated; indeed, their existence was not suspected. The study of English dialects according to the old methods has reached the end of its tether. The problems are now being stated afresh in the light of new knowledge, from hitherto unexplored sources, of the history of English at every period. The point of view from which the study is approached is changing, and there is an ever-increasing attempt to link up the facts collected about the language of the different periods, so as to present a picture of continuous development. The old view of circumscribed dialect areas with rigidly fixed boundaries is slowly disappearing, and we are beginning to realise that an ideally 'pure' dialect hardly exists, except, perhaps, in the very centre of a dialect area. As research progresses upon new lines, some of which we can already foresee, it is inevitable that much of the elaborate, but inadequate, system of the past will vanish. Our methods will be ampler, more historical, our analysis more penetrating and subtle, our classifications surer and more precise.

§ 85. PHONOLOGICAL CHARACTERISTICS WHICH DISTINGUISH THE CHIEF DIALECTIC TYPES IN O.E.—*W. Sax.* This, the most important of all the O.E. dialects, on account of its literary development, displays certain features which, so far as we know at present, are not found in any other form of O.E.

1. *Diphthonging of front vowels after front consonants.*—This very characteristic *W. Sax.* feature has been illustrated above, § 3, 6.

2. Development of diphthong *ē* as *i*-mutation of the old diphthongs *ēā*, *ēō*, no matter what their origin. See § 3, 7 (*h*). This *ē* becomes *i* already in Early W. Sax. in King Alfred's dialect; in the more westerly area, it first remains, but appears later as *ȳ* (see § 95 (g) for M.E. developments).

3. Survival of Prim. O.E. *æ* as *such*. See § 2, 1. For non-W. Sax. see § 86, 3.

4. Un-rounding of *ȳ* to *i* in part of W. Sax. area, before *ēg*, *ē*, *sā*, *ht*, *n*: *drūhten* 'lord,' *brīce* 'useful,' *bricg* 'bridge,' *risc* 'rush,' *cining*, &c., for earlier *dryhten*, *brȳce*, *brycg*, *rysē*, *cyning*, &c.

5. Combination *sel-* becomes *siel-*, later *sil-*, or *syl-*; cf. 2, above, for treatment of *ie*: *sellan*, *sulan*, *syllan* 'give, sell,' from *sellan*; *sietf*, *sulf*, *syf*, from *self*.

§ 86. FEATURES SHARED BY ALL NON-W. SAX. DIALECTS.—1. Absence of *ē* as *i*-, *j*-mutation of *ēā* (§ 3, 7 (*h*)): non W. Sax. *hēran* 'hear,' *beldan* (or *bældan*) 'encourage,' *ermþu* 'misery.'

2. Absence of diphthonging of front vowels after front consonants (§§ 3, 6; 85, 1).

3. Raising of Prim. O.E. *æ* to *ē* (§§ 2, 1; 85, 3). This is found in the earliest non-W. Sax. texts: *dēd* 'deed,' *sēton* 'they sat.' See, however, § 97 (*b*), below.

4. Prevalence of *u*-mutation. All non-W. Sax. dialects tend to diphthongise *i* and *e* when followed in next syllable by *-u*, *o*, *a*: *geofu*, from *gefū*, *sceopum* dat. pl. of *sēp* 'ship,' *begeotan* from *begeatan*, &c.

§ 87. Characteristic Features of Kentish.—1. Raising of O.E. *æ* (*i*-mutation of *a*, cf. § 3, 7 (*b*)) to *ē*.—In distinction to the great majority of the O.E. dialects, Kentish texts of the 9th century habitually write *ē* in *clēwa* 'cleaner,' *dēlan* 'divide,' *mest* 'most,' &c. This process was certainly not confined to Kent, though owing to the considerable number of texts from this area which have survived it is more generally recognised as a feature of Kentish than of any other dialect. It is found, however, in a 9th-century Surrey charter, and in two others from Suffolk. It was certainly not a feature of the more westerly dialects, nor, in the old period, of the Nthn. See § 12 on the M.E. distribution.

2. Typical Kentish *u*-, *o*-mutation.—This process seems to have been more unrestricted in Kentish than elsewhere, and it is characteristic of the dialect that the diphthonging takes place before back consonants, no matter what the initial consonant of the word may be: *brego* 'prince,' from *brego*; *forespreoca* 'advocate,' from *forespreca*.

3. Earlier O.E. *ȳ* becomes *ē*.—In Late O. Kentish such forms as *gelt* 'guilt,' *senn* 'sin,' &c., earlier *gylt*, *synn*, &c. (§ 3, 6 (*f*) and (*g*)). There is evidence that the change had occurred in the 8th-century Kt., though not expressed in the spelling till later as a rule. The *e*-spellings occur also in a 10th-century Suffolk charter, and if the early records of the S.E. and S.E. Midl. dialects were complete, it would probably be shown that the distribution of these forms was far wider in the O.E. period than can be conclusively proved at present. See §§ 18, 19 for the M.E. conditions.

4. Absence of fracture of Prim. O.E. *æ* before the *l*-combinations (cf. § 3, 1 (*c*)).—It seems certain from the evidence of the early charters that in parts of the Kt. area, at any rate, diphthonging did not take place, since such forms as *haldan*, W. Sax. *healdan* 'hold,' occur. The Surrey charter also has unfractured forms.

5. Prim. O.E. *æ* becomes *ē*: *dey* 'day,' after 'after,' *weter*, from *dæg*, *æfter*, *wæter*.

§ 88. Mercian Features.—1. *æ* becomes *ē*.—This change, as in Kentish, appears in the Sthn. Mercian area.

2. *u*-mutation of Prim. O.E. *æ* (*a*): *ic fearu*

'I go,' W. Sax., &c., *fare*; *steadelas* 'foundations,' from *stædulas*. This change appears to be confined to Merc.

3. Levelling of *ē* and *ēā*.—The latter diphthong, which in Merc. undergoes no further change from *i*-mutation, is written *eo*, and is indistinguishable from original *ēō*: *weorþeþ* 'becomes,' from **wiorþip* (W. Sax. *wierþ*); *eorre* 'angry,' from **iurri* (W. Sax. *ierre*); *lēoseþ*, from **cūsiþ* (W. Sax. *cūsep*). (Cf. § 89 for Nthmb. treatment.)

4. Absence of fracture of *æ* before *ll*, &c.: *cald* 'cold,' *ald* 'old,' *all* 'all.' See also § 87, 4; and § 3 (*c*).

5. 'Smoothing' of Diphthongs before back and front consonants.—As in Nthmb., diphthongs were monophthongised in Merc. in this position: *hūh* 'high,' from *hēah*; *bilēc* 'locked,' from *bilēac*; *ēc* 'also,' from *ēac*.

§ 89. Northumbrian Features.—1. O.E. *æ* remains in Nthmb., and is not raised to *ē* as in Merc.

2. O.E. *æ* is not diphthongised as in Merc. by *u*-mutation.

3. Distinction between *ē* and *ēō* is preserved: *gestrōna* 'to gain,' &c., Merc. *-stirōnan*; *þrōstro* 'darkness,' Merc. *þrōstro*; *hiorde* 'shepherd,' Merc. *heorde* (W. Sax. has *ēē*).

4. (*a*) *weo-* (fracture of *e*) becomes *wo-*: *worþu*, from *weorþan* 'become'; *sword* 'sword,' from *sweord*. (*b*) *weo-* (*u*-mutation) becomes *wo-*: *woruld* 'world,' from *weoruld*, in Northern Nthmb. area.

5. In combination *we-*, the vowel is rounded and written *oe*: *woeg* 'way,' from *weg*; *cwoeða* 'to speak,' from *cweðan*.

6. In Sthn. Nthmb., Prim. O.E. *eo*, whence later *ēā* (§ 2, 4), remains at *ēō* stage: *dēōþ* 'death,' elsewhere *dēap*; *dēōf* 'deaf,' elsewhere *dēaf*.

7. Nthn. Nthmb. writes *ea* for earlier *ēō* (§ 3, 1 (*b*)): *hearte* 'heart,' elsewhere *heorte*; *earðu* 'earth,' for *eorþe*.

8. Sthn. Nthmb. of 10th century writes *eo* for *ea* (§ 3, 1 (*c*)): *eorm* 'poor,' instead of *earm*.

§ 90. M.E. DIALECT FEATURES.—All that can be attempted here is to enumerate some of the main characteristics which distinguish severally the great dialect groups, without entering into detail as to the more specific combinations of features found in particular localities within each area. The references to the paragraphs where the general development of M.E. is dealt with will, as a rule, make it unnecessary to add examples.

§ 91. THE NORTHERN GROUP.—(*a*) O.E. *ā* fronted to [ǣ-ē-ē], &c., whence Mod. Nth. Engl. and Scots [stēn, stīn] 'stone,' &c., instead of being rounded as in Midl. and Sth., § 10.

(*b*) O.E. *æ*¹ and *æ*², both levelled under [ē] by 14th century in some areas, in others distinguished as [ē (i)] and [ē (ē)] till later.

(*c*) O.E. *ō* was fronted to a vowel of the character of [ȳ] and rhymes with French *ū*, e.g. *fortune*—*sūne* 'soon'; the vowel is variously written *u*, *oi*, *oy*.

(*d*) The *i*-mutation of O.E. *ēā* is *ē*, cf. § 86, 1.

Verbal forms.—(*d*) Pres. sing. and pl. *-is* endings; (*e*) inf. without ending; (*f*) pret. pl. of strong verbs according to singular type; (*g*) p.p. of strong verbs, no *i*-prefix; ending *-en*, or none; pres. part, *-and*; pres. pl. of *Be*, *are*, *ar*, *bēs* (*bēn*).

Nouns.—(*h*) Strong type almost universal.

Pers. Pronouns.—(*i*) 3rd fem. sing. *scho*, &c., cf. § 60; 3rd pers. pl., Scand. *th*-type in N. G. D., cf. § 62.

§ 92. WEST MIDLAND DIALECT FEATURES.—

(*a*) O.E. *æ* becomes *e* (e in Sthn. area), § 9.

(*b*) O.E. *ā* becomes *ō* in South (§ 10).

(*c*) O.E. *æ*¹ (§ 11) is tense [ē].

(*d*) O.E. *æ*² (§ 12) is [ē].

(c) O.E. *ȝ* (§§ 18, 19) largely preserved, and written *u*.

(f) O.E. *eo* (§ 22) appears frequently as [ȝ], written *eo*, *oe*, *ue*, *u*.

(g) *i*-mutation of O.E. *eo* is *ē*, cf. § 86, 1.

Verbal forms.—(h) Pres. sing. as Sth. or *-uþ* in 3d pers., but 2d and 3d pers. sometimes *-s* in more northerly area; (i) pres. pl. *-en*, *-un*, *-in*, in central area, but *-ep*, *-ip*, in Sth. part, and *-us*, *-is*, in Nth. of area; (j) pres. part. *-ing* very early in Sthn. area; *-end(e)*, *-and* further Nth.; (k) p.p. of strong verbs no prefix, ending *-en*, *-un*; (l) pres. pl. of *Be*, *arn*, *bēn*, *bēp*.

Pers. Pronouns.—(m) 3d pers. fem. generally *hwe*, &c., but *sche* also in 14th century; (n) pl. forms of 3d pers.: Engl. and Scand. forms in N., Engl. forms in G. and D.; (o) unstressed flexional sylls. often *-ud*, *-us*, *-un*, but also *-id*, *-is*, &c.

§ 93. EAST MIDLAND FEATURES.—(a) O.E. *ā* becomes *ō* as in Sth. and W. Midl.

(b) O.E. *æ* usually *ā*, but *e* in some early texts from southerly area.

(c) O.E. *æ*¹ appears as [ē].

(d) O.E. *æ*² generally [ē], but also [ē] in some more southerly areas.

(e) O.E. *ȝ* generally *ȝ*, but *ē* also common in most areas in the 14th century, and probably developed already in O.E. period in Sthn. parts of area.

(f) O.E. *eo* appears as *ē*, which probably developed in Suffolk at any rate, in late O.E. period.

(g) *i*-mutation of O.E. *eo* is *ē* (§ 86, 1).

Verbal forms.—(h) 3d pers. sing. *-ep*, but *-es* early in Lincs.; (i) pres. pl. *-en*; (j) pres. part. *-end(e)*, *-and* in northerly area, *-ing* in early 14th century in Lincs.; (k) pres. pl. of *Be*, *aren*, *bēn*.

Pers. Pronouns.—(l) 3d pers. fem. *scē*, *schē*, &c., very early, also more rarely *ghē*, &c.; (m) pl. forms of 3d pers. *hē*, *he*, predominate, except in Lincs. in 13th century, later *thei*, &c., though not sole form; in dat. *hem* predominates except in Lincs., in gen. *here* far more common before 15th century; (n) note the peculiar acc. pl. *hes*, *hus*, *es*, *is*, as in S., Eastern, which occurs sporadically in S.E. Midl.

§ 94. CENTRAL MIDLANDS.—Of the special dialect features of this area, we have at present practically no knowledge for the M.E. period, beyond the important point that the sound of O.E. *ȝ* was largely retained, written *u*.

§ 95. SOUTH-WESTERN DIALECT FEATURES.—

(a) O.E. *æ* remains at first as a front vowel *e*, but is very early exchanged for the Midl. *a* type.

(b) O.E. *æ*¹ and *æ*² both survive as a slack vowel [ē].

(c) O.E. *ȝ* survives in part of the area, and is written *u* and *uy* respectively, but there appears to be a considerable area stretching from the extreme west to the east as far as Wilts, and gradually contracting in Glos. and Hants, in which un-rounding took place.

(d) O.E. *eo* (cf. § 22) appears as [ȝ] written *u* as in W. Midl.; there are traces (*dure*, O.E. *deor* 'dear') as late as *Shillingford's Letters* (Devon, 1447-50); in early M.E. the *u*-forms must have been current as far east as the western borders of Surrey.

(e) The O.E. combination *-eald* (fracture before *-id*, § 3, 1 (c)) appears in early texts as [ēld], written *-ēld*, *-eald*, but soon gives way to the Midland *-old*-type, from *-ald*, cf. § 21.

(f) Survivals of L. W. Sax. *cy-* from *cie-* (§§ 3, 7 (h), and 23) appear in some early texts as *chule*, O.E. *ciclu*, &c.

(g) W. Sax. *ē* late W. Sax. *ȝ* (§§ 3, 7 (h), and 23) survives at first, written *u*, or *ui*, *uy* when long, but by the end of the 14th century is largely ousted by the non-Sax. type *ē*—*ēlde* instead of W. Sax. *uile* 'age', *hēren* 'hear', instead of W. Sax. *hūren*.

(h) Initial *f*, especially in Eng. words pronounced voiced, and written *v* or *u*.

Verbal forms.—(i) Pres. sing. 2d pers. *-est*, 3d *-ep*;

(j) pres. pl. *-eþ*; (k) pres. part. *-inde*; (l) p.p. strong and weak verbs, prefix *i-*, *y-*, from O.E. *ge-*; (m) p.p. ending of strong verbs *-e*; (n) inf. *-e*, *-ie*, *-y*; (o) pres. pl. of *Be*, *bup*, *bēp*, *bēp*.

Pers. Pronouns.—(p) 3d fem. *sche*, &c. unknown before 15th century, normal forms *heo*, *huc*, *he*, *hi*; (q) 3d pers. pl. nom. *hi*, *heo*, *ha*, *hoe*, *þey* in 15th century; dat. *hcom*, *ham*, *hom*; gen. *hor(e)*, *hare*, *here*, *hure*; (r) there is no trace of acc. pl. *his*, &c., as in S. Eastern (§ 96).

§ 96. FEATURES OF S.-EASTERN GROUP, INCLUDING KENTISH.—(a) O.E. *æ* survives as a front vowel, *ē* longer than in other areas, especially in Kt. and Essex.

(b) O.E. *æ*¹ became [ē] in Kt. early in O.E. period and remains as such in M.E.; in Essex, however, the slack type [ē] was also current (§ 11).

(c) O.E. *æ*² (§ 12), the change of this to *ē*, tense, is typical of Kt. in O.E. period (§ 87, 1), and this type remains in M.E.

(d) O.E. *ȝ* written *e* in Kt. texts in later O.E. period (§ 87, 3), and the *ē*-forms remain typical of pure Kt. in M.E., with occasional *i*-forms; in Essex both *e* and *u* are written, and the same is true apparently of Sussex.

(e) O.E. *eo* (§ 22) was written *ie*, *ye*—*huerte*, *friend*, &c., in Kt. texts as late as 14th century, and to some slight extent also in Essex texts; also O.E. *eo* constantly written *ia*, *ya* (*dyap*, &c.) in Kt. It is very doubtful whether these spellings indicate diphthongal pronunciation, but they are nevertheless a mark of dialect. Cf. the very different development in S.W. (§ 95 (d)).

(f) O.E. *-eald*, *-earn*, survive as *-ēld*, *-ern*, longer in this area than elsewhere (cf. S.W. conditions in § 95 (e)).

(g) Initial *s* often written *z*, and *f* as *v* or *u*.

Verbal forms.—(h) Pres. sing. 2d and 3d *-est*, *-ep*; (i) pres. pl. *-eþ*; (j) pres. part. *-inde*; (k) p.p. prefix *i-*, *y-* typical; (l) strong p.p. ending *-e*; (m) inf. *-ie*, *-ye*, *-y* typical; also *-e*; (n) pres. pl. of *Be*, *bēp*, *bēp*, *bēp*.

Pers. Pronouns Pl.—(o) Engl. *h*-type only; (p) fem. sing. *hi*, never *sche*, &c.; (q) *his*, *hes*, &c. very typical as acc. pl. 'them' (§§ 63, 93 (n), 95 (o)).

§ 97. FEATURES OF LONDON DIALECT IN M.E.—This, the most important form of English in view of its subsequent destiny, is to be regarded primarily as a variety of S.E. Midl. It has been frequently referred to in the *General Introduction*, in the preliminary remarks on Engl. Dialects, and incidentally in the various sections dealing with *Sounds* and *Inflections*. The following is a brief summary of the chief features presented by this dialect in the 14th century, especially as exhibited in the works of Chaucer. They should be compared especially with those of E. Midl. and S.-Eastern groups.

(a) O.E. *æ* represented universally by the Midl. *ā*-type.

(b) O.E. *æ*¹ predominately [ē] so far as can be tested by the rhymes, but occasionally the [ē] type is used.

(c) O.E. *æ*² usually appears in slack [ē] type, but occasionally rhymes with undoubted [ē] words.

(d) O.E. *-eald*, generally *-ōld* in Davie and Chaucer (from O.E. *-ald*-type), but also slight traces of *-ēld* (from O.E. *eald*-type). The fractured forms regular in 13th century.

(e) O.E. *-earn* usually *-arm*, but the other type in *yerd*.

(f) Mutation of O.E. *eo*, always *ē*, according to non-Sax. type.

(g) O.E. *eo* always *ē*. (Note, however, the typical *fill* from O.E. *fēoll* 'fell,' perhaps shortening of [ē], which had already approached [i] stage.)

(h) O.E. *ȝ* appears in all three forms—*u*, *i*, *e*. The *e*-forms predominate in many words, as

Chaucer's rhymes show; the *u*-forms are well represented, but gradually give place to *i*-forms.

(i) O.E. *eh*, *ēz* though often written *eh*, *ehh*, *ey*, have become *ih*, *i*, as is shown by Chaucer's rhymes. From this type are derived Mod. *high*, and (the pronunciation of) *eye*, O.E. *hēh*, *ēze*.

(j) Pres. sing. 2d pers. -*est*; 3d pers. *ep*.

(k) Pres. pl. -*en*, -*e*, very rarely -*eth* in Chaucer. In 13th century, however, -*ep* seems still the normal form.

(l) Pres. part. -*inde* in 13th century, always -*ing* in Chaucer.

(m) P.p., prefix *i-*, *y-*, regular in early documents and in Chaucer, but dropped in an official late 14th-century petition.

(n) Strong p.p. ending -*e* before, and in Chaucer's works, but -*en* in late 14th-century petition.

(o) Pl. pres. of *Be*, *bēp*, *bēon*, *bēn*, before Chaucer; Chaucer himself usually *been*, *bee*, rarely *arn*; later documents *been*, *bup*, *arn*, *ar*.

Pers. Pronouns (see §62).—(p) 3d fem. sing. *she*, &c. always in Chaucer.

(q) Pl. 3d pers. *hi* in N. before Chaucer, who has only *they*; Engl. *h*-forms in gen. and dat. in Chaucer; *them*, *their*, unknown till early 15th century, and then but rarely used.

(r) Acc. pl. *his*, *hes*, occur in 13th-century Lambeth Homilies, which must represent the dialect of London area, but no trace of such forms occurs in any actual London documents.

BIBLIOGRAPHY. [For O. and M.E. Dialects see general Bibliography above.]—*Works on Modern English Dialects*.—A. J. Ellis, *Modern English Dialects* (Pt. V. of Early English Pronunciation); J. Wright, *English Dialect Grammar, English Dialect Dictionary, Grammar of the Windhill Dialect* (1892); T. O. Hirst, *Grammar of the Dialect of Kendal* (Westmorland), Bonn, 1906; A. Hargreaves, *Grammar of the Dialect of Adlington* (Lancs.), Bonn, 1904; J. Cowling, *Dialects of Hackness* (Yorks.), Cambridge, 1916; H. Mutschmann, *Phonology of the North-Eastern Scotch Dialect* (Bonn, 1909); J. A. H. Murray, *Dialect of Southern Counties of Scotland* (Trans. Phil. Soc. 1872-73); W. Grant and J. M. Dixon, *Manual of Modern Scots* (Cambridge, 1921); A. Vikar, *Durham Dialect* (1922); H. C. Wyld, *Standard English and its Varieties* (Mod. Language Teaching, Dec. 1913).

The above are among the most important general and special works. The publications of the English Dialect Society consist chiefly of a number of dialect glossaries representing many of the counties. They are often uncritical, and are now largely superseded by Wright's *Dialect Dictionary*.

English Literature is, in its largest sense, the mind of the English-speaking races, expressed in successive generations by the fittest representatives of each succeeding form of thought. All conflicts of opinion through which decisive action has been reached lie, with their opposing arguments and with the passions they excited, in the books that form the literature of a people; these show for each nation, in strength and weakness, all the workings of the mind that shaped its history. Such a literature must express also the slow forward movement towards higher civilisation, coloured variously by the influences of race and climate, and brought home to us by fellow-feeling with the individualities of earnest men.

Before the English came with power into Britain there was a Celtic population of the Gael and of the Cymry, each with a literature diffused chiefly by rhythmic recitation. Many traditions of later invention, with perhaps a few snatches of the oldest song, that passed with no great change from lip to lip of generations living in some secluded home among the hills, carry the mind back to a Gaelic literature that gathered much about Fionn, Oisín, and the battle of Gabhra, said to have been fought in the year 284. In like manner we have traces of a Cymric literature, strongest in the time

of battle for home and country against English invasion. Tribes of the Celts in Britain gathered their forces for a last firm stand, and were overthrown at Cattraeth; Aneurin's poem, the *Gododin*, which celebrates the chiefs who fell, tells us of this battle. To the battle of Cattraeth there has been a date assigned, the year 570. If King Arthur ever lived, he lived in that 6th century, and shared its struggle.

Various Low-German tribes from the other side of the North Sea (see ENGLAND) had been finding their way over to the eastern and southern coast for many years before the time of the six settlements which Bede described (449-547). By the year 570 the settlements of English on the eastern and southern coasts had made sure their predominance. With them they brought the common lore of the Germanic peoples, the matter epic and elegiac, and no doubt lyric, of their minstrels' poetry. When this poetry was first written down is not known, but several surviving poems and fragments preserve the memory of the common Germanic world upon which the eyes of the minstrels were turned, from which they drew their subjects and their heroes with no visible tribal partiality. The poet of *Widsith* ('Far-traveller') may have lived in the 7th century; some think the 6th. *Deor's Complaint* shows us the minstrel in elegiac mood. *Beowulf* (q.v.) and the fragments of *Finn'sburh* and *Waldere* are the only remains of our old epic. The Exeter Book (see below) contains, besides *Deor*, a fine group of early elegiac poems, *The Seafarer*, *The Ruin*, *The Wanderer*, *The Husband's Message*, *The Wife's Complaint*, poems in which winter landscapes and sea pictures of great beauty are invested with an atmosphere of reflective melancholy. In all the poems yet mentioned the Christian element, where it is present at all, is easily separable. It may often be an interpolation by a duller versifier. Purely pagan literature is hardly to be found.

But there is another body of Old English poetry which is definitely Christian. Its strength was in the north. The fervour of the Celt brought to the conversion of the northern English a noble zeal and self-devotion. The abbess Hilda, who drew Cædmon into the fellowship of her monastery at Whitby, in which men and women worked together for the spreading of the gospel, was taught in the Columban school. The work of Cædmon was to spread among the people knowledge of the Bible story, in what is now called a 'paraphrase,' that took the form of poems shaped for recitation by the people to each other upon festival occasions, or by the men who made it their vocation to chant tales of battle and adventure. A hymn of Cædmon's has been preserved. Whether any part of the so-called 'Cædmonian' *Genesis*, *Exodus*, and *Daniel* be his is very doubtful (see CÆDMON). Cædmon died about the year 680; and Bede, who tells us of him, was in the year 680 a child of seven. Aldhelm, whose English songs, familiar in King Alfred's time throughout the country, are now lost, was then a young abbot of twenty-four, who had devoted his life and fortune to a work at Malmesbury like that of the abbess Hilda at Whitby. With these monasteries were associated many forms of labour for advance of civilisation, including, of course, the formation of schools. Bede in the monastery at Jarrow became the first great teacher. He shaped, in Latin, manuals for use in education, and thus his works serve as an encyclopædia of the best knowledge of his time. He gathered also, by wide inquiry, materials that were digested into the first *History of England*; that was his *Eccelesiastical History*, finished in 731. The history of the church in those first days was inseparable from that of

the people among whom it had laboured in its missionary work.

The 8th century, to which Bede's work belongs, was the golden time of Old English literature. To it probably belongs *Beowulf* (see above), which, like the *Cædmonian* paraphrase, survives only in a single MS. With few exceptions the other pieces of the oldest English literature have as narrowly escaped total destruction. We owe our knowledge of them to the preservation of two MS. collections; one known as the Exeter Book was presented by Bishop Leofric, near the time of the Norman Conquest, to Exeter Cathedral; the other is the Vercelli Book, which was discovered in 1822 in the cathedral at Vercelli. One poet's name is preserved—Cynewulf (q.v.)—interwoven by himself in runes with pieces of his verse. He wrote *Elene* and other church legends in verse of merit, but his date is doubtful. Probably he lived in the 8th century, or early in the 9th. In that time of greatest energy of thought among the Anglo-Saxons, the empire of Charlemagne drew light from a Yorkshirian, Alcuin, who was appointed to do for its monasteries and their schools what might be called the work of a great minister of public instruction. He had been born in 735, the year in which Bede died, and it was in 782 that he took up his residence at Aix-la-Chapelle.

But when Alcuin died in the year 804, the simpler question of the establishment of Christianity had passed into the more complex forms of battle against heresies, of struggle to maintain full uniformity of theological opinion. At the same time advance of thought was being checked in England. There were continued attacks of the Northmen, some of whom were trying the mettle of King Alfred, at the same time that others were following Rollo up the Seine to lay the first foundation of the Norman power. Those who followed Rollo in 876 learned in Normandy the language of the women of the country from which their descendants afterwards crossed over to England to make conquest of a kindred people. In the 9th century John Scotus Erigena, born possibly in Ireland, possibly in Ayrshire, was an acute thinker established at the court of Charles the Bald. He wrote a Latin book *On the Division of Nature*, which, by its endeavour to bring the teaching of theology into philosophical harmony with other teaching in the schools, yet without opposition to a single dogma, laid the foundation of what is called the Scholastic Philosophy.

King Alfred was then living, and working strenuously for the revival of lost learning. Ruin of a monastery meant in those days the annihilation of a school; and the ravages of the Danes had caused such decay of learning that in re-establishing the ruined schools Alfred translated the most important books of the schools into the language of the people. For Latin could no longer be the language through which studies were pursued. Orosius, whose *Universal History* had been a school-book, was thus translated, with omission of whatever was not practical, and with addition of new geographical detail. Bede's *History* was translated. A favourite school-book for ethical training had been Boethius *On the Consolation of Philosophy*. That also was translated by King Alfred. For the higher training of the clergy the king, justly named Great, turned into English Pope Gregory's book on the *Pastoral Care*; and to him also is ascribed the foundation of the continuous record of the annals of the country, known as the *Saxon Chronicle*, which now and then had afterwards an entry in verse, especially, under the year 937, a poem on the battle of Brunanburh (q.v.). The noble work of Alfred, who died in October 901, filled his kingdom of Wessex

with new life, and the centre of intellectual energy was thus removed from north to south. The work of Alfred's son and grandson spread this new influence, until, in 954, the grandson, Eadred, free of the last of the under-kings, ruled over all England from the Channel to the Firth of Forth. The centre of intellectual energy was then the midland region, which included the five boroughs that had been strongholds of the Danes in Mercia. But after the death of Alfred, Old English literature passed into work associated with honest endeavour to restore religion by restoring strictness of monasticism. The chief interest of this period for us is in the *Homilies* of Ælfric, who wrote books also to aid his work of teacher in the school at Winchester. Ælfric's *Homilies* were upon the series of days kept holy by the church, and thus we have in them an exposition of the doctrines of the Church of England at the end of the 10th century. The first of the two sets in which they were arranged was written in the year 990. A poem on the battle of Maldon near the same date tells a victory of the Danes over Byrhtnoth, who was killed in the battle. It has much of the old spirit of the poems written, as this also was, for recitation to the people.

The Norman Conquest brought a royal court in which French was familiar, while Latin was the common language of the learned throughout Europe. Friends of the Conqueror held all the places of high trust, and of those who had money to spend few would pay it for written records of the English pieces still recited to the country-people. From 1066 till about the year 1200, except in a few religious writings of no great importance, literature speaks the thoughts of Englishmen through French or Latin. The *Chronicle*, however, went on till 1154. The literature in the language of the people had not ceased to be; but there was nobody who cared to put it upon record. Even where it was already written, it might be rubbed from the parchment to make a palimpsest in which English was replaced by French or Latin.

Of the literature written in Latin after the Norman Conquest, a very large part was monastic chronicle. Every great religious house set up its chronicle, which might begin with Adam or with Hengist and Horsa, but which, wherever it began, was a compilation of no value till its record came near to the date of writing. Then it included facts yet within living memory, and became more and more valuable as a record of the past, until it became, for the occurrences of each successive year, the testimony of a living writer. From these chronicles we have our surest knowledge of the past. They were written usually by men whose sympathies were with the church and with the people, who cared little for pomp and show, but had clear notions about duty. There was strength of England in their practical simplicity. The most important of the monastic chroniclers were Ordericus Vitalis, who wrote an *Ecclesiastical History of England and Normandy*, and William of Malmesbury, who wrote a *History of English Kings*. Each closed his chronicle and probably his life about the same time, 1141-42. In William of Malmesbury the arrangement of the narrative showed a chronicler who had the genius of a historian. Milton placed him next to Bede. About the year 1147 a stream of romance broke from among the hills in the *History of British Kings*—British as distinguished from English—by an imaginative Welsh ecclesiastic, Geoffrey of Monmouth. This Latin chronicle, enriched by its author's fancy, began with the mythical origin of Britain in Brut, a great-grandson of Æneas, and went on through tales of kings, as Gorboduc and Lear, from which our poets afterwards drew

subjects for their verse. These led to stories of King Arthur, who in this book came to life again, and became the hero of that cycle of romance in English literature which answers to the cycle of the Charlemagne romance in France and Italy. Geoffrey of Monmouth's Chronicle was abridged by Alfred of Beverley; it was turned into French verse by Geoffrey Gaimar and also by Wace, whose version supplanted Gaimar's and abides in literature as Wace's *Brut*. Romances of Arthur, Merlin, Lancelot, Tristan, were supplied abundantly as the demand for them increased. Walter Map was a man of genius, chaplain to Henry II. He (if it was he) attacked abuses of the church with witty Latin poems, setting forth a Bishop Gollas as type of the fleshliness in which the spiritual life of the church was being lost. Walter Map perhaps arranged the chief Arthurian tales into a sequence, and put soul into them by uniting them inseparably with the spiritual allegory of the Holy Gail. Thus, within forty years after they had first come into our literature, the tales of King Arthur were associated, as they still are, with the spiritual life of the English people.

After the year 1200 English regained its place in literature as the language of the country, and we have an increasing number of MSS. containing works by Englishmen written in English, as well as in French and Latin. To a date near 1205 is assigned an English poem of about 56,000 lines, in which the famous story told by Wace in French was told again by Layamon, a priest living near Bewdley by the Severn. Layamon's *Brut* is the first extensive piece of literature in Early Middle English, and near to it in date is a large fragment of a work named from its author, a canon of St Austin's order, Brother Orm or Omin, the *Ormulum*. This was a metrical arrangement of the series of gospels appointed to be read in church throughout the year, set forth in simple narrative, each of them followed by a little homily upon it, written in like manner for pleasant recitation to the people. Both are interesting to the prosodist. The old alliterative verse is in decay. Layamon wavers helplessly between alliteration and rhyme. Orm rejects both for wooden regularity. To this period belongs also the rise of the Robin Hood and other ballads, and the telling in English verse of romances, such as those of *Havelok* and of *King Horn*. To this period belongs also a much greater achievement. Dialogue literature was no new thing in English—we have an Old English *Salomon and Saturnus*, for example—but *The Owl and the Nightingale* is Chaucerian long before Chaucer, 'the most miraculous piece of writing,' as Professor W. P. Ker put it, 'among the mediæval English books.' It may be by Nicholas of Guildford or by John of Guildford, or by some other totally unknown. It is assigned to the reign of John.

The foundation of the Dominicans as preaching friars for the maintenance of orthodoxy in religion, and of the Franciscans for the spread of the religious life by brotherhood with the poor, was in the beginning of the 13th century. Books being forbidden property to the Franciscans, they escaped from bondage to their records of opinion, looked straight to nature, and advanced the knowledge of the outward world. The first rector of a Franciscan house at Oxford was Robert Grosseteste, who in 1235 became Bishop of Lincoln, and made strenuous war against abuses of the Roman government of the church. He found that three times the revenue of the king of England was being paid for the support of absentee Italians, to whom the pope gave English church livings. Roger Bacon, who settled at Oxford as a Franciscan under Grosseteste, died after the year 1294, and had produced the most advanced body of scientific know-

ledge, the result of independent thought and experimental research, then to be found in Europe. He set it forth in his *Opus Majus*, *Opus Minus*, and *Opus Tertium*, all poured out in fifteen months to satisfy the pope's request for an account of what he knew. Robert of Gloucester's chronicle from the siege of Troy to the death of Henry III. in 1272 put English history into verse for diffusion among the people, still chiefly by recitation. In the reign of Henry III. appeared in October 1258 the first proclamation in English since the Conquest. There was not another in that reign. At the close of the 13th century the wisdom of the people was gathered also into the metrical *Proverbs of Hendyng*.

At the beginning of the 14th century the religious spirit of the people was expressed by Robert of Brunne's metrical version—as the *Handlyng Synne*—of a *Manuel des Pêchés* that had been written in French by a Yorkshireman, William of Wadington. There was in the popular poem of 'The Land of Cockayne' a homely satire on the sensualism that had spread among the monks, who now had too much to live upon and too little to do. The miracle-plays that first came into use after the Conquest had developed greatly. Early in the 14th century long sequences of Bible story, then first set forth in the language of the people, were so dealt with by trade-guilds as to be a great means of bringing the Bible into the street, and vividly presenting to the people the events on which the forms of their religious faith were founded. Such sequences of miracle-plays have come down to us—the Chester, the Coventry, the Wakefield or Towneley, and the York. There are known to have been more than these, and they did not wholly go out of use until the reign of Elizabeth. Englishmen then had Bibles to read in their own tongue, and had learned to read them, so that there was no more need for the device of an *Ormulum* or of a sequence of miracle-plays to show what they contained. To the beginning of the 14th century belongs also an outburst of lyric of singular freshness and delicate beauty.

While English literature was in such ways the voice of the nation, the genius of Dante had raised literature in Italy to its highest artistic form, the higher for close union with all that was felt to be most real in life. The year 1300 is the assumed date of the *Divina Commedia*. Dante, who died in 1321, was followed by Petrarch (born in 1304), and by Boccaccio (born in 1313). Petrarch and Boccaccio were the great living poets of Italy when Chaucer's genius was being shaped in England. They died nearly at the same time—Petrarch in 1374, Boccaccio in 1375, when Chaucer was in ripest manhood, and the better artist for the influence these great Italians had upon his work.

But energies of thought in care about essentials were the main cause of the strength of English literature in the 14th century. There was continued provision of monastic chronicles, also of religious poems, one of them, the *Cursor Mundi*, of great length. But a new mind found utterance. Decay of spiritual life in the church, as its wealth became its weakness, and caused poets and reformers to lament 'the fatal gift of Constantine,' had given cause for earnest questionings and struggles for reform. At the university of Paris, in 1324, Marsiglio of Padua had controverted the sacerdotal limits of a church, had declared only Christ the judge of heresy, and had broken with the medieval view of papal authority. In this country William of Ockham, called the invincible doctor, argued boldly against the pope's power in temporal affairs. It was he who brought the Scholastic Philosophy to a close by reasoning upon doctrine without faith in the infallibility of dogma. The great movement of the 14th century towards reform

was prompted by visible corruption. Wyclif himself as a reformer looked at first mainly to discipline, with which questions of doctrine became gradually more involved. For seventy years, from 1309 to 1378, the popes were at Avignon under French influence, and this quickened English resistance to their claims. For the next forty years or more the influence of the papacy was further weakened by the rivalry of two popes, one in France and one in Italy. Thus, while John Wyclif, who died on the last day of the year 1384, having secured between 1360 and 1382 a complete translation of the Bible into English, represented in our literature of the 14th century a strenuous reform movement within the church, William Langland, in a great poem addressed to the people at large, the *Vision of William, concerning Piers the Plowman*, sought to animate men to the search for Christ, and battled vigorously with church corruptions. Five great pestilences in the 14th century—the greatest the Black Death of 1348–49—were regarded as signs of divine wrath against sin, and added much to the intensity of feeling. Langland, who wrote his Christian poem, which made love ‘the triacle of heaven,’ between 1362 and 1400, seems to have been urged to utterance by the great pestilence of 1361. Multiple authorship has sometimes been claimed for his work. *Piers the Plowman* is written in the old alliterative verse which, with a changed rhythm, but otherwise fairly well preserved, had in some obscure way lived on to emerge in the 14th century. A greater than Langland was among its practitioners, the anonymous ‘Gawain poet,’ the strong imaginative genius who, probably in Lancashire or Cheshire, wrote the romance of *Sir Gawain and the Green Knight*, the allegory of the *Pearl*, and the didactic *Cleanliness and Patience*. Contemporary with him was at least one other alliterative poet of merit, ‘Huchown of the Awle Reale.’

The Jack Straw rebellion of 1381 caused John Gower, a wealthy gentleman, religious, liberal, and with distrust of Wyclif’s followers, to seek the source of all ills of the land by a review in his Latin poem, *Vox Clamantis*, of all orders of society. In this, although an orthodox churchman warning against heresies, and one who had no sympathy with popular violence, he wrote with emphasis of the corruption of the papacy and the gross appetites of the religious orders. Gower wrote three great books, and wrote them in what still were the three languages of English literature. His book written in French, *Speculum Meditantis*, was lost till 1896; that in Latin was the *Vox Clamantis*. In his English poem, the *Confessio Amantis*, Gower, like Chaucer, followed the lead of Boccaccio’s *Decameron* in threading together upon a connecting narrative a series of tales. Like Chaucer’s, they were told in verse. Gower’s tales were moralised to illustrate the seven deadly sins, and one book dealt with a question pressed on the country by the gross misrule of Richard II., the duties of a king. Gower lived until 1408, blind during the last eight years of his life. Geoffrey Chaucer died in 1400. In the *Canterbury Tales*, with their Prologue and the rest of the connecting thread of narrative, as well as in other writings, Chaucer shows a genius akin to Shakespeare’s. Not only is there a rare dramatic power manifested clearly, but he had also the calm sense of highest truth, and that kindly breadth of human sympathy without which a power such as Shakespeare’s cannot be. In his other poems Chaucer seems in earlier life to have been influenced by the French poets fashionable at court; but he came more and more under the influence of the great Italian masters. His *Troilus and Cressida* and his *Knight’s Tale* are free

versions of two of the most famous poems written by Boccaccio, and the influence of Dante was upon his later work. In the north, while Chaucer wrote, the spirit of liberty maintained by the endeavours of the kings of England to extend their sovereignty beyond the Tweed produced from John Barbour, Archdeacon of Aberdeen, his poem of the *Bruce*, which was half-finished in 1375. To Barbour has been attributed also a collection of church legends which were printed in 1881–82.

In the earlier half of the 15th century there were many influences adverse to the maintenance of the high standard of English literature. There were civil wars and there was foreign war of aggression, part of the endeavour of the kings of England to maintain and extend sovereignty in France. None of these wars were inspiring to the men on the south side of the Tweed. Scots and French were driven to alliance against a common danger; and in battle for their independence the Scots bred the better poets. In England at the beginning of the 15th century there were, indeed, two poets of mark, John Lydgate and Thomas Hoccleve or Hoccleve, each of them about thirty years old when Chaucer died. Hoccleve was a clerk in the office of the Privy Seal, who wrote in English his chief poem *De Regimine Principum*, on the duty of kings, that it might be humbly presented to King Henry V. as a reminder to him that Hoccleve and other clerks in the government service could not get payment of their salaries. Without disloyalty Hoccleve pointed out the evil of aggressive war. John Lydgate, an accomplished monk of Bury St Edmunds, had travelled in France and Italy before he became the most famous teacher in his time of rhetoric and poetry. He drew many to the monastery school of Bury St Edmunds, and himself wrote much good verse that was in high repute. Besides many short pieces and lives of saints, he wrote especially three larger poems—one was his *Troy Book*, on the siege of Troy; another was the *Story of Thebes*, with a pleasant introduction linking it to Chaucer’s *Canterbury Tales*; the third, his most important work, was the *Falls of Princes*, a version through the French verse of Laurent de Premierfait, from the Latin prose of Boccaccio’s *De Casibus Illustrium Virorum*. James I. of Scotland, captured as a child, instructed in English manners as a prisoner at the English court, married to a cousin of Henry V., and crowned at Scone in 1424, was too manly to be made a puppet in the hands of England. His poem, the *King’s Quair*, celebrating his love for Jane Beaufort, is one of the best pieces written as in the school of Chaucer; and if, as is now hardly accepted, he was also the author of a piece so homely and vigorous as *Pebbles to the Play*, with its humorous scenes of life among the people, he had a master’s breadth of power.

Wyclif’s followers were rigorously persecuted in the earlier years of the 15th century. In 1449 Reginald Pecock was raised from the bishopric of St Asaph to that of Chichester, and on the part of the bishops undertook an answer to the complaints made by the Lollards against the higher clergy. His answer, the *Repressor of over much Blaming of the Clergy*, a large work in English prose, admitted their right to be reasoned with, and gave to reason the same place that was assigned to it long afterwards by Richard Hooker, when he opposed the Puritan view at the end of Elizabeth’s reign. There are, indeed, many points of resemblance between the arguments of Pecock’s *Repressor* and those of Hooker’s *Ecclesiastical Polity*. But Pecock, because he reasoned with the people in their own tongue, instead of compelling obedience, was condemned by his own order, and imprisoned for the rest of his life in Thorney Abbey; while Hooker

for like service in a later time won honour as a champion of the church. Civil as well as religious liberty was represented even in our scanty 15th century literature by Sir John Fortescue, Chief-justice in the reign of Henry VI. Fortescue, when his king's cause was lost and he was an exile in France with the queen and the young prince who might hereafter be king in England, gave to the prince a lesson on the limits of an English king's authority, comparing it with the absolutism of the king of France. He wrote like a sound constitutional lawyer on the *Difference between Absolute and Limited Monarchy*, and about the year 1463 *De Laudibus Legum Angliæ*. By that time new powers had begun to work in Europe for the shaping of the future. The capture of Constantinople by the Turks in May 1453 drove into exile many learned Greeks, who earned their living in Italy and elsewhere by teaching. They had a ready welcome at Florence, where Cosmo de' Medici was establishing his power. There began in this way a diffusion of Greek studies, through which Plato came to life again, and his doctrines came in strong aid of the movement against fleshly corruptions of the church. A saying that arose then, *Cave a Græcis, ne fias hæreticus*, shows the supposed tendency of these new studies. At the same time a new force, which would quicken greatly the formation of opinion in the world at large, was coming into life through the discovery of the art of printing with movable types. In 1455 the printing of a Bible with such types was finished. The working printers, presently dispersing, carried their profitable skill to other places. There was a press at Rome in 1466, at Paris in 1469, and the new art was brought into England by Caxton about 1477. The 15th century closed with another event fruitful of great consequences—the discovery of the New World (1492).

Luther and Raphael, born in the same year, 1483, were youths of eighteen in the first year of the 16th century; Michelangelo and Ariosto were young men of twenty-six. The intellectual predominance obtained by Italy through the free life of her republics was not immediately destroyed by the establishment of petty tyrannies as single families won mastery over their fellow-citizens. The new lords, of whom Lorenzo de' Medici (who died in 1492) was a great typical example, spent freely the money of their subjects upon luxuries of art. They led the way in encouragement of every form of intellectual life that could keep active minds busy upon other questions than those which concerned their ancient rights. At the little Italian courts every gentleman was, to the best of his power, a small artist who cultivated ingenuity in clothes, in manners, and in words. When our English youth travelled, in Henry VIII.'s time, into Italy for polish, they brought home fashions of speech and writing that developed in new form an Italian influence upon our literature. This was not, as in Chaucer's time, the influence of one great writer on another, but the diffused social influence of a prevailing fashion.

Struggle for independence had raised poets in Scotland, of whom there is a long list in William Dunbar's *Lament for the Makars*, first printed in 1508, when Andrew Millar and Walter Chepman had just set up the first press in Edinburgh. Robert Henryson, schoolmaster of Dunfermline, shrewd, homely, and religious, author of the first pastoral in our literature, *Robin and Makyn*, of a sequel to Chaucer's *Troilus and Cressida*, the *Testament of Cresseid*, and of translations from Æsop's fables, was then dead. William Dunbar himself, the next great poet after Chaucer, may have been about forty years old when he received, in 1500, a pension of £10 Scots from James IV., whose marriage with Henry VII.'s daughter Margaret, in

1503, he celebrated with his poem of the *Thistle and the Rose*. It was probably in 1501 that Gavin Douglas dedicated to James IV. his poem of the *Palace of Honour*. In July 1513, two months before the disaster at Flodden, Gavin Douglas finished the earliest translation of the *Æneid* in our literature, with verses of his own to introduce each book. Gavin Douglas, become Bishop of Dunkeld, died of the plague in 1522, a pensioner at Henry VIII.'s court. Dunbar was dead in 1530. David Lyndsay, who became Sir David Lyndsay of the Mount, was associated with James V. of Scotland from his infancy, and addressed to him many admonitions on the sorrows of the people and the duty of a king. Lyndsay's *Satire of the Three Estates* was the most important example in our literature of the Morality Play that expressed moral teaching by the dramatic action of personified attributes and forms of life. It shadowed forth the reform wanted in the Church of Scotland; and the passing by the Estates in 1540 of what was called a friendly act of reformation was prepared for by the public acting of this satire in the presence of the king. Lyndsay's last poem, the *Monarchie*, was finished in 1553, and in this 'the Scottish poet of the Reformation,' as he has been called, becomes distinctly Lutheran. The vigour of these poets of the north was not equalled in the south under Henry VII., where Stephen Hawes, a gentleman of the king's chamber, wrote, among other poems, a *Pastime of Pleasure*, with an allegory of the course of life in knightly adventures, that show distinctly, but in form only, the advance of allegorical literature towards its crowning work in Spenser's *Faerie Queene*. John Skelton, who had been chosen for his scholarship to be a tutor to Henry VII.'s children, wrote in the reign of Henry VIII. satires against church corruption, in little torrents of short lines with continuities of rhyme, verse called Skeltonical. It poured out the complaints of *Colin Clout*, who represented the poor Englishman of country and of town, and it boldly attacked Wolsey himself in the height of his power. From Skelton, with whom he had fellow-feeling, Spenser borrowed afterwards for himself the name of Colin Clout.

Greek scholarship was still advancing, and was still associated with the free advance of thought. William Grocyn, having learned Greek in Italy, first taught it at Oxford in 1491. The physician, Thomas Linacre, who had also learned Greek in Italy, taught also at Oxford. In 1497, when Erasmus sought to learn Greek, he came from Paris to Oxford for it. John Colet, the founder of St Paul's School in 1510, and William Lily, its first headmaster, were Oxford scholars, associating their Greek studies with ideals of true life and a wise liberality of thought. Thomas More when at Oxford was inspired by these men, and his *Utopia* (Latin, 1516; Eng. trans. 1556) imagines a commonwealth in the New World lately discovered, and through playful wit brings thought inspired by Plato and by Plutarch into the Christian ideal of a higher policy than statecraft yet had known. More sought also to bring home the teaching of the Gospels by a Latin paraphrase. Translation of the Scriptures into the language of the people had many learned advocates who were restrained only by fear of mistranslations that would, as they thought, corrupt the Word of God.

Luther's translation of the New Testament into German appeared in 1522. Tyndale's translation into English followed in 1525. Sir Thomas More was its adverse critic, because he found Lutheran bias in the choice of words. In 1530 Tyndale finished printing his translation of the Pentateuch, made with Miles Coverdale's help. In October 1536 Tyndale was strangled and burnt near Brussels. In the same year Coverdale's completed translation of the Bible was admitted into England, and work

towards the production of a translation that would satisfy all judgments was continued.

From Italy there flowed new streams of literature. The *Arcadia* of Sannazzaro, finished in 1504, was in a form of pastoral that spread to other lands. The first eclogue of mark in France was Clément Marot's *Complaint on the Death of Louise of Savoy*, mother of Francis I., written in 1531, and paraphrased afterwards by Spenser in the eleventh eclogue of the *Shepherd's Calendar*. George of Montemayor, a Portuguese, produced in 1542 a *Diana Enamorada*, which joined force with the *Arcadia* of Sannazzaro as an influence on English literature. Blended with influences from the Spanish romance of chivalry, it led to Sir Philip Sidney's romance of *Arcadia*, first published in 1590, after Sidney's death. Of the same parentage came also a long line of French romances, which continued far into the 17th century.

The modern drama, based upon the form of Latin plays then usually acted, had its rise in Italy. Ariosto first wrote comedies about the year 1498; his earliest, *I Suppositi*, was based on the *Eunuch* of Terence, and the *Captives* of Plautus. Trissino's *Sofonista*, dedicated to Leo X. in 1515, and first printed in 1529, was the first Italian tragedy of mark. The Italian sonnet was first imitated in Henry VIII.'s reign by Sir Thomas Wyatt and the Earl of Surrey. Experiments in unrhymed verse by the Italian poets led to the first use of blank verse in English literature, when the Earl of Surrey used it in translating two books of the *Aeneid*, which had been so turned into Italian.

The great question of church reform became more passionate, and divided all Europe into two camps, which came to have their headquarters, one at Madrid, the other in London. Luther had died in 1546, when Calvin's age was thirty-three, and Calvin died at Geneva in 1564. Hugh Latimer preached before King Edward, and was burnt by Mary. John Knox, indignant against three ruling Maries, sounded from Geneva his *First Blast of the Trumpet against the Monstrous Regiment of Women*, just before the accession of Elizabeth. He could not make his peace with her, but, warned from England, he landed at Leith, and stirred Scotland to the heart with religious zeal. It had its aims in accord with the teaching of Geneva, but was associated by Knox with a masterly reshaping of provisions for the education of the people.

In Elizabeth's reign the struggle for all that they most prized, against Spain enriched by the wealth of the New World, lifted the hearts of men as the hearts of the old Greeks were lifted when they fought for freedom against Persia. Fashions and follies there were then as now, chiefly brought in from Italy, with an exuberance of ingenuity that touched alike the clothing of men's bodies and men's thoughts. Thus the Italian influence, which became dominant over outward forms, introduced that straining for conceits and dainty turns of speech, alliteration, and antithesis, which was so common as to need a name. It was called Euphuism from *Euphues*, the hero of a book by John Lyly, published in 1579, and written in the fashionable manner. Lyly wrote in that manner to win hearing. His aim was to advance a view of the need and nature of true education, which had been urged by one of the best scholars of the day, Roger Ascham, in his *Schoolmaster*, first published in 1570, two years after its author's death.

In the first twenty-one years of Elizabeth's reign English energies were growing. *The Mirror for Magistrates* is in the mediæval succession, but its 1563 edition had one contributor of genius, Thomas Sackville. In 1579 Edmund Spenser, aged about twenty-six, produced his first book, the *Shepherd's Calendar*, following Clément Marot in his way of

applying pastoral images to the religious conflicts of the time, and boldly taking his place beside the disgraced Archbishop Grindal, with whose firmness in encouraging free search for Scripture truth the poet was in sympathy. In the same book Spenser paid homage to Tityrus (Chaucer) as his master. He took the style of Chaucer for his model, avoiding the false emphasis laid on tricks of thought and phrase. Spenser was Chaucer's successor, Milton's predecessor. In the great fragment of his *Faerie Queene*, which represents man through all his powers for good striving heavenward, and attaining only by the intervention of the grace of God—of which Prince Arthur is the bearer—all militant forces of his time have their expression. The *Faerie Queene* is throughout an intense utterance of the spiritual life of England under Elizabeth, in all that were then the forms of the long battle towards a higher life for man. England was full of song. Men felt proudly the rising vigour of their country. A tailor (John Stow) was inspired to write its annals. An attorney (William Warner) wrote in verse of *Albion's England*. The defeat of the Spanish Armada in 1588 removed the common danger that had knitted Englishmen together. In 1589 the Maiprelate tracts against the bishops, and the replies to them, brought oppositions of opinion in the English Church into that bitter conflict of which Francis Bacon, then twenty-eight years old, pointed out the unseemliness in a paper addressed to the government on *Controversies in the Church of England*. Shakespeare's age was then twenty-five. He had come to London probably when twenty-two, two years before the defeat of the Spanish Armada, and at that time the English 'regular' drama was but twenty-five years old.

The first English comedy, *Ralph Roister Doister*, a version of the *Miles Gloriosus* of Plautus, had been written between 1534 and 1541 to be acted by Eton boys. It was a schoolmaster's chance substitution of English for Latin in a play written by him for his boys; and it was acted under conditions that would not prompt imitation. Its production, therefore, was an isolated fact. But the first tragedy, *Gorboduc*, by Thomas Sackville and Thomas Norton, acted in the Inner Temple at Christmas, 1560—actually on the first of January 1561—was a substitution of English for Latin in an English play written in the manner of Seneca, that drew to itself the attention of many young men who could write. Its grave dwelling upon the need of union to keep a people strong, a truth of deep significance to England at that time, pleased Elizabeth. The play was acted again before her, by command. It set an example that was followed at court, where English plays came into request. It showed also to young wits how they might furnish themselves with money by writing English plays to be acted by those gentlemen's servants who already had formed little companies for playing *Interludes*. Such interludes, short entertainments in dialogue by a few servants of the house, who used their skill in mimicry for the amusement of their lord and his guests, produced a form of literature in which John Heywood excelled. But these short pieces had no developed plots. Desire grew towards the new way of showing tales in action. It was an improvement on the most dramatic recitation by a single story-teller. But in the twenty-five years from 1561 to 1586 few plays of high mark were produced. There was little more than a wide spreading of the taste for the new kind of entertainment, and a development of companies of actors. At length a civic opposition drove the actors privileged to play in London out of rooms and inn-yards in the city into buildings of their own, just outside the jurisdiction of the mayor and corporation, which they erected for sole use as

theatres. These first theatres were built in 1576. Ten years afterwards Shakespeare came to London when the new conditions of the stage had made the way ready for plays of higher mark. John Lyly had produced court plays chiefly mythological. George Peele had already pleased the queen with his *Arraignment of Paris*. Christopher Marlowe began with *Tamburlaine* upon the public stage in 1586 or 1587, his short and brilliant career ending in 1593. Robert Greene, who died in 1592, Thomas Lodge, Thomas Kyd, and others maintained a poetical drama during the six, or about six, years of what may be called Shakespeare's apprenticeship. During these years he made himself generally useful, acted, and sometimes turned old plays into new. At the end of the six years this group of dramatists, the pure Elizabethan, passed away; and for the next six years, 1592 to 1598, in which Shakespeare was master, writing plays of his own, he seems to have had no strong competitors. But in or about the year 1598 many young dramatists—Ben Jonson, Dekker, Marston, Thomas Heywood, Middleton—who were to earn fame in the next reign began to write, while Shakespeare went on with his work, remaining foremost of all. Beaumont and Fletcher, Massinger, and Ford did not write any plays until after the death of Elizabeth. Webster wrote his two finest plays in the reign of James I., and emphasised, like others in his time, that element of terror in the drama which Aristotle had joined to pity. Webster lived into the middle of the 17th century. James Shirley, who was only nine years old when Elizabeth died, and who wrote plays chiefly in the reign of Charles I., lived until 1666, the last of those who are usually called Elizabethan dramatists. The period of highest achievement in our English poetical drama falls, then, within the first ten or twelve years of the reign of James I. But already in this best time of fruitage there are conditions of decay, which make it hard to say where ripening ends and rotting begins. The energies of struggle had developed a dramatic literature in Spain as in England. Influence of the Spanish drama, coinciding with a lower social tone in James's court, caused many of the plays of younger dramatists to find in intrigues of animal love the sole groundwork of invention. On the stage of Elizabeth's time there was no such restriction, but interest was shown in all the trials of the life of man.

The 17th century, from the accession of James I. in 1603 to the Revolution of 1689, was occupied by new forms of struggle about the limit of authority. Becket's struggle with Henry II. had been for sovereignty of the church over the king. From that time onward, Reformation movements chiefly were for war against the pope's claim of dominion. While England was in contest against Spain, Elizabeth was leader of her people. When removal of the danger from abroad gave freedom for domestic difference, the queen became unpopular. There was dread that civil war would come again after her death. The two chief heroic poems at the close of her reign, Drayton's *Barons' Wars* and Daniel's *Civil Wars of York and Lancaster*, were designed—as other poems and plays were then designed—to press on Englishmen a feeling of the ills that follow when this house is raised against this house. When James I. sought less wisely than Elizabeth to maintain and magnify the power of the sovereign, he soon made the question of the limit of authority political as well as religious, and prepared the way for civil war in the next reign.

Revolt against authority of mere tradition in the teaching of the schools had its chief leader in Francis Bacon, whose analytical mind looked in his *Essays* upon the nature of man himself, and in

his philosophy upon the nature of the world without him. His two books of the *Advancement of Learning*, with which he began to lay foundations for his *New Organon*, were published in 1605, and his work as teacher of the right way of experimental search into nature, unimpeded by tradition, was suggested by a strong reaction against bondage to common opinion (the Idol of the Forum) or the teaching of great men who have played large parts on the stage of life (the Idols of the Theatre). Men with a bent for science began to inquire as Bacon counselled that they should, and grew in desire towards unbiased inquiry by well-planned experiments. They were searchers into nature so inspired who were incorporated in London as a Royal Society in 1662.

But James I., though Bacon's patron, knew little of the whole advance of free inquiry that Bacon represented only in one form of study. To obtain freedom of worship, English Puritans sailed for New England in the *Mayflower* in 1620, and added strength to the foundations of an England on the other side of the Atlantic, which had its origin in the vigour of Elizabethan navigators. Part of the region that Sir Walter Raleigh named Virginia, after the virgin queen, was granted by James I. in April 1606 to a London company, whose first settlers called their town Jamestown, in honour of the king, and who produced in Captain John Smith the author of a *True Relation of Virginia*, published in London at the close of the year 1608. This may be regarded as the first book in the English literature of America. The settlers in New England who had left Old England for conscience' sake, and who included many graduates, of Oxford and especially of Cambridge, brought a new strength to the New English world that is well represented in the record of the Mather family.

John Milton went to Cambridge in the year (1625) when Charles I. became king. He joined fine scholarship and the poet's temperament to strenuous endeavour towards freedom of thought. His high ideals were expressed with the power of a master poet who had subjected his mind to long and patient training. His earlier verse was pastoral, as he thought suited to a time of preparation for a higher flight; but the period of his prose works intervened between his earlier verse and the later in which he rose to the epic with *Paradise Lost*, published in 1667. His other epic, *Paradise Regained*, was published in 1671 with *Samson Agonistes*, his one drama, modelled on the Greek. In the controversies of the day about religion, Milton was the best representative of the first principle of the Independents. They would unite all men as fellow-Christians who built their faith upon the Bible, and would leave to each the right of joining himself to an independent congregation of the worshippers with whom he best agreed in his interpretation of the Bible. Richard Baxter was the ideal type of the Presbyterian who thought the Episcopal Church less scriptural than a church managed by presbyters and elders, but was as desirous as the ruling church to bring all Englishmen into accord with one church discipline and one form of belief. Of the church established by Elizabeth as *via media* between Rome and Geneva, the church of which Richard Hooker in his *Ecclesiastical Polity* had, at the end of Elizabeth's reign, best maintained the cause, Jeremy Taylor was in Stuart days the ablest supporter. God made us to differ that by wrestle of opinion we may win the victory for truth.

Milton's early poems were written at a time when the English drama seemed to break in its fall into a rainbow-tinted spray of song; Herrick, born lyricist, Wither, Suckling, Cartwright, Habington, Thomas

Traherne, Randolph, Cleveland, Lovelace, Cowley, Crashaw, George Herbert, and Henry Vaughan represent the graces and the follies and the grossnesses of life, the stife of parties, and the highest aspirations towards the divine ideal. Milton's *Comus*, the most beautiful example of the masque, which before Milton had been best developed by Ben Jonson, was an indirect plea for the high use of the poet's art, when Prynne had just expressed the Puritan antipathy to plays, masques, dances, in his *Histriomastix*. *Comus*, acted at Ludlow in 1634, was also a setting forth of the beauty of temperance and purity, at a time when the course of fashion, aided by the readiness of the king's friends to show that they were no Puritans, was bringing sensuality into repute. Dr Thomas Browne of Norwich—not Sir Thomas till the time of Charles II.—in his *Religio Medici*, published in 1642, joined faith in doctrines of the church with a free, reverent spirit of inquiry. Every page of that book was rich with subtle utterance of independent thought. Milton's prose pamphlet *Areopagitica* in 1644 enshrined in a piece written carefully after the manner of a Greek oration the cardinal principle that for the advance of truth there is no safeguard to be relied upon but free exchange of thought. 'Let truth and falsehood grapple,' Milton said; 'who ever knew truth put to the worse in a free and open encounter? Her confuting is the best and surest suppressing.'

This is the battle that runs through the history of English literature. All the prose writings of Milton in the Commonwealth time dealt essentially with the question of the limit of authority; they sought the best solution of the problem between king and people that had stirred up civil war. The Commonwealth was an experiment that failed. The Restoration was a going back to a new starting-point, and trying again for an answer to the problem. It was found at last in 1688. The argument for absolute authority had its best expression in the political philosophy of Thomas Hobbes, whose *Leviathan* appeared in 1651 as his contribution to the great controversy of the time. James Harrington's *Oceana* in 1656, and Richard Baxter's *Holy Commonwealth*, show the energies at work which have made English literature at all times a true and full expression of the people's life. They were in George Wither's verse and Andrew Marvell's satire; in Butler's *Hudibras* with a wide reach of wisdom in its wit that struck at everything insincere; in *Paradise Lost*, that shapes an epic to maintain God's love among the discord of disputes about predestination and free-will; in *Paradise Regained*, with its calm burden of Rest in the Lord, enforcing faith and patience in the darkest times—dark even as the times seemed to religious men who looked at the court and country in 1671—and in *Samson Agonistes*, which was added as a scriptural example of such faith. In all work of the best writers there was the best life of the time engaged upon its most essential problems. John Bunyan's *Pilgrim's Progress* in 1678 and 1684 found its answer in the religious feeling to which it appealed, still strong throughout the body of the people. The masterpiece of John Dryden, *Absalom and Achitophel* in 1681, and the poems that next followed, dealt altogether with those vital questions of the day which pointed to the coming revolution.

Strain for ingenious conceits had been an Italian fashion that spread to Spain and to France as well as to England. In all three countries it became laboured, and took the form called by Samuel Johnson 'metaphysical,' in the poetry of which John Donne in the reign of James I. was the favourite writer. At the same time Marino in Italy and Gongora in Spain illustrated the same form of decay. Our days of Euphuism were repre-

sented in Spain by the school of the 'Conceptistas,' and those whom we may call our later Euphuists were represented by the school of 'Cultos.' In France reaction against this laboured extravagance had begun in the days when English royalists of the time of Charles I. were in political adversity and lived in Paris. They who afterwards in England were patrons of literature attended the *salons* of the Marquise de Rambouillet, and were in contact with the critics and the poets who prepared the way for the predominance of France. Boileau, the master critic of this school, began his satires about the time of the Restoration, and summed up his views in his *Art Poétique* in 1673. A taste for criticism now spread; even the small wits prided themselves on sense. Boileau lived until 1711. Critics who followed his teaching in the letter rather than the spirit swarmed about him and survived him. The period of Latin-English thus came in, when writers, to avoid the low association of ideas with homely words, sought their vocabulary from the Latin side of the language, and wrote sentences that they would never speak.

Boileau opposed the strain of writers for extravagant conceits—which he called the paste brilliants of Italy—by fixing attention on the simplicity that graced the highest art in Roman literature of the time of Augustus. Works of Virgil and Horace were the models through which he would have nature to be studied. This was right counsel, but many misapplied it. In England they grew blind to the art of their own best writers who were not in obvious relation with the new French school. Deaf to the music of Chaucer and Spenser, they supposed that Waller, whose earliest verse was written in the reign of Charles I., and who died, aged eighty-two, in 1687, had been the first in England who wrote smooth verses and invented the right use of rhyme. Sir John Denham's poem on the view from *Cooper's Hill*, first published in 1643, was exaggerated into epic dignity. Dryden described it as a work that, 'for the majesty of the style, is and ever will be the exact standard of good writing.' Dryden was then advocating the disuse of blank verse in our plays, and he used for a few years the rhymed couplets preferred in France which found their way into the heroic play of the Restoration. These heroic plays, of which the first had been Davenant's *Siege of Rhodes*, were sustained in popularity by Dryden himself with plays like his *Tyrannic Love* in 1669, and *Conquest of Granada* in 1670. They retained much of the extravagance against which, on behalf of good sense, Boileau made elsewhere successful war; and the *Rehearsal*, by the Duke of Buckingham and others, produced in 1671, was a burlesque meant as a plea for good sense even in the theatre. The heroic plays passed into rhetorical tragedy, of which only two pieces by Otway, *Venice Preserved* and the *Orphan*, avoiding royal heroes, were distinguished by domestic pathos. But Charles II. left Otway to starve. The rhetorical tragedies became associated with an artificial stage delivery until the time of Garrick, who went straight to nature. In the comedy of the Restoration, Sir George Etherege's profligate young gentlemen, who call themselves men of sense and have no reason in their lives, reproduce with a light touch, a grace of gracelessness, the fashionable manners of the time. But Molière, greater than Plautus or than Terence, had raised comedy in Paris to an intellectual supremacy that was felt by the best comic dramatists in England. Wycherley, whose four comedies were produced in the reign of Charles II.; Congreve, whose plays were all written under William III.; Sir John Vanbrugh, and Farquhar, who wrote also in the reign of Anne, learned from Molière to put a larger life into their art as dramatists, and produce what

has been entitled the Prose Comedy of English Manners.

Until nearly the end of the 18th century this French influence prevailed. It was maintained by the just predominance of French literature, which had reached its Augustan age; but this influence, like that of Italy, had in its strength an element of weakness that increased with years. In due time it was shaken off by one more great reaction, out of which came the forms of literature in the present day.

The 18th century in English literature shows especially the course of thought between the English Revolution of 1688, of which John Locke expressed the true ideal, and the French Revolution of 1789, that sought to establish an ideal of true citizenship. It failed, but showed the way to a success much slower of attainment, towards which the English literature of the 19th century labours in every generation with more conscious resolve. The 18th century was not an age, as Carlyle once called it, 'of shams and windy sentimentalities.' There were plenty of these; but the spirit of the century lies really in the great reaction against them. Corruptions in that section of society which usually calls itself the World, that touched religion to the quick, and put formal convention in the place of truth, had stirred resentment. Pierre Bayle, in his *Dictionnaire Historique*, implied in all his pictures of the lives of men a world without a God. A scepticism of earnest, honest minds grew up, that denied God because it could see no truth in his priests. The corruption of society, greater even in France than in England, great in both countries through the evil lives of men whose high social position made them leaders of the weak, made vice appear to be the sand upon which civilisation had been built. Mandeville's *Fable of the Bees* began, even in Queen Anne's time, the satirical expression of this doctrine, which had its highest expression afterwards in France, through the writings of Rousseau. First there was this growing conviction of wrong; then followed in France the passionate desire for remedy.

There arose in Queen Anne's reign, from the genius of Daniel Defoe, the real beginnings of the modern newspaper and of the periodical essay. Newsletters, intended to give information to one side or other in the time of civil war, had already been published before the Commonwealth. After the Restoration, Sir Roger L'Estrange, having obtained for himself the 'sole privilege of printing and publishing all narratives, advertisements, mercuries, intelligencers, diurnals, and other books of public intelligence,' produced in August 1663 the first number of his *Public Intelligencer*. When the plague drove the court to Oxford, he produced, in November 1665, the first number of his *Oxford Gazette*, which became, when the court returned to London, the *London Gazette*, on the 5th of February 1666 (see GAZETTE). Other newspapers arose, which expressed opinion indirectly by representing facts in the form most agreeable to their subscribers. Daniel Defoe, having been sent to Newgate in 1703 for an ironical pamphlet against passionate attacks on the Dissenters, began, after his liberation, his journal, the *Review*, of which the first number appeared on the 19th of February 1704, and which appeared in and after 1705 three times a week until June 1713. This paper had two features which were new, and upon these the growing power of English journalism at its best was based. Defoe aimed at exact truth, palatable or unpalatable, in his record of facts; and he joined to his record independent comment. Thus he became the founder of what is now known as 'the leading article.' He also added to his *Review* a monthly

supplement that dealt wholesomely with follies and fashions of society. The notion of this was developed afterwards by Richard Steele when he established the *Tatler* in April 1709. Out of the *Tatler* came Steele and Addison's *Spectator*, which began on the 1st of March 1711, and opened the way to many later efforts of the same kind to better and refine the ways of men.

In the foundation also of the modern novel of real life, which displaced the French romances of Gomberville, Calprenède, and Madeleine de Scudéri, themselves due, as we have seen, to Spanish romances and Italian pastorals, Defoe led the way with his *Robinson Crusoe* in 1719. This did not profess to be a novel, but was, like all following novels of Defoe, written in imitation of some other form of literature that had for its chief features a true record of experience of life. Defoe's picture of a single man battling against circumstance, unflagging in the energetic use of his own resources, with unfailing trust in God, expressed so completely the new interest in the development of man, that Rousseau afterwards, in his *Emile*, made *Robinson Crusoe* the first book to be put into the hands of the ideal pupil. As the movement towards larger assertion of individual and national life advanced in Germany, imitations of *Robinson Crusoe* were so many as to form a group in literature that became known as the *Robinsonaden*.

Pope, under Queen Anne, followed the critical fashion of the time, and made his mark first in 1711, with an *Essay on Criticism*, which was writing about writing about writing. His *Rape of the Lock*, in 1712-14, was, perhaps, the daintiest trifle ever written; but it was half-earnest play upon the idleness of fashion. Under George I. Pope earned money by translating Homer. But under George II. he had grown with the growth of his time, and to the full extent of his powers he dealt in his *Essay on Man*, his *Satires* and *Epistles*, with the deeper questions of life, and felt with the world about him that 'the proper study of mankind is man.' From the beginning of the reign of George II. our best literature expressed the growing interest in questions of the nature and the prospects of society. Swift, under Queen Anne, had followed the critical fashion of the time with his *Battle of the Books*, but joined to it the keen use of his wit in dealing with the dissensions about religion. That was in his *Tale of a Tub*. His other writings in Queen Anne's reign belonged almost without exception to those controversies of the day that shaped the course of history, and to the labour to let light into the lives of men. Under George I. Swift was Dean of St Patrick's, deep in politics of Ireland. At the end of that reign his *Gulliver's Travels* (1726) expressed the meanness to which life and its aims had sunk, not more contemptuously than Gay's *Beggars Opera* (1728), and its sequel *Polly*, which placed highwaymen a little above, savages high above, the pollutions of a civilised society. In 1725 and 1726 Allan Ramsay's *Gentle Shepherd*, Thomson's *Winter*, and Dyer's *Grongar Hill* sent a healthy breath into our literature, the first sign of a renewed sense of the beauty of outward nature. Thomson completed his *Seasons* in 1730, showing, with distinct reference to the scepticism of the time, in the world that surrounds us, God, 'parent of good.' Pope sought in his *Essay on Man*, in 1732-38, to reason against those who believed that man and nature replied 'No' to the question, 'Is there a just God?' Butler's *Analogy* was published in 1736—an effort of sheer reasoning against the same creed of despair.

The same controlling force was upon all forms of life. It touched alike the pulpit and the stage. Garrick's triumph as an actor was a triumph of natural over conventional expression. 'If this

young fellow is right, we are all in the wrong,' said the old actor Quin. Even as late as 1768 and 1772, when Goldsmith's comedies, the *Good-natured Man* and *She Stoops to Conquer*, were produced, conventional notions of dignity and traditions of false sentiment caused alarm in the breasts of managers. Sheridan's *Rivals* in 1775, and *School for Scandal* in 1777, continued the emancipation of good wit from trammels of an artificial style. Collins's poems, first collected in 1765, and Gray's in 1768, foreshadowed, with exquisite art, something of the new in the forms of the old.

Good Samuel Richardson was with his time more fully than he knew when in his first novel, *Pamela*, in 1740, he asked his readers to care for the sorrows of a maid-servant. Henry Fielding in his novels painted life full of the spirit of the coming change. Byron afterwards described him as 'the prose Homer of human nature.' Fielding's *Tom Jones*, published in 1749, is a great landmark on the way from the English Revolution of 1688 to the French Revolution of 1789. Nature reasserts herself in the fresh liveliness of Smollett's novels, the last of them published in the year of his death, 1771. Fanny Burney's *Evelina* and *Cecilia* followed in 1778 and 1782; without breaking from the conventional, long-worded style, they were unconventional in substance. There was quick, fresh observation, with a grace of wit in their invention and character-painting. They were followed at the beginning of the 19th century by the works of Maria Edgeworth and Jane Austen.

Samuel Johnson died in 1784, after forty-seven years of life in London. In 1738, after his first year's struggle with poverty as a Grub Street author, he had published his *London*, a phrase of Juvenal's third satire. He won his way as a man of letters, never rich, but always firm to his own sense of right, delighting in the society of men, strong in wit combats, deeply religious. By his character he first gave its right dignity to the position of the professional man of letters. His toast to the next insurrection of the blacks, and his interest in the negro Francis Barber, whom he took as a servant, educated and treated as a friend, in visible protest against the valuing of man by the colour of his skin, may stand among many evidences of Johnson's part in the new sense of the fellowship of man. His *Rambler*, in 1750-52, following the *Spectator* in its aim, reduced to system the critical theory of the time, that sought for dignity on the Latin side of English. But Johnson lived with his time and led his time, and the style of his *Lives of the Poets*, written in 1779-81, is not that of the *Rambler*. When in 1764, Goldsmith in his *Traveller*, which, according to its second title, was a 'Prospect of Society,' expressed the spirit of the time in mournful review of the nations of Europe, it was his friend Johnson who added those last lines that spoke the language of the 19th century, by showing that the solution of the great problems of life lies for each man within himself. Goldsmith's *Deserted Village*, in 1770, expanded a passage in the *Traveller* into a picture of depopulation caused by greed of wealth, and yet more strongly expressed the new sense of social inequalities. It also combined a charm of simplicity with what was really dignified and graceful in the old style that was giving way before impatience of formalism. The *Vicar of Wakefield*, in 1766, in substance and in manner a poet's novel, expressed even more completely the advance of time. The transition from rhetorical forms to a style founded directly upon nature is well marked in Goldsmith and in Cowper. They are on the way to Wordsworth. A strong spirit of freedom was in them. In her old age, the daughter of his friend Lord Clare described Gold-

smith, whom she had known in her youth, as 'a strong republican in principle, who would have been a very dangerous writer if he had lived to the times of the French Revolution.'

In other forms of literature there was a corresponding movement. David Hume, whose philosophy raised honest questions which put more clearly and forcibly the doubts that startled a faith based only upon traditional opinion, completed his *History of England* in 1761. Begun as a history of the Stuart times before the English Revolution, it became the first work in which the whole course of English history was told with an intellectual sense of sequence in the affairs of men. The first volume of Edward Gibbon's *Decline and Fall of the Roman Empire* appeared in 1776, the year of the death of David Hume. The last volume was published in 1788, the year before the fall of the Bastille. The book was suggested by the sight of Rome in ruin. Its design was, in days when modern states seemed tottering, to draw from Rome a study of the causes of decay. The scepticism of the 18th century was in Gibbon the more strongly marked by an elaborated pomp of words that contrasts with the philosophic calm and simplicity of David Hume. The year of the first volume of Gibbon's great work was the year also of the publication of Adam Smith's *Wealth of Nations*, crown to an arch formed by a series of studies on the nature of society and on the grounds of its well-being, that had its spring in the days of Charles II. from Sir William Petty, and passed through Locke's second *Essay on Civil Government* to Adam Smith. The first volume of Blackstone's *Commentaries on the Laws of England* appeared in 1764, and Jeremy Bentham began his career as a political economist with *A Fragment on Government, being a critique on Blackstone's Commentaries*, published in the same year as the *Wealth of Nations* (1776), the year in which Malthus was born. Thenceforward the study was continuous, though the social system it contemplated was just about to be transformed.

The year of the publication of the *Wealth of Nations* was the year also of the Declaration of Independence on the 4th of July by the English American colonies, which on the following 9th of September were first termed by Congress the United States. When the political action of this country made such an issue likely, the eloquence of Burke was spent in the endeavour to avert the revolution. The colonists would not bear taxation for imperial purposes without representation. The English government maintained the right to tax. 'Assert the right,' said Burke, 'but do not use it.' That was, in brief, the policy of the Rockingham administration which Burke inspired, and in association with which he began to devote his mind to the great questions that touched the destiny of nations. The American Declaration of Independence gave to the world another England in the New World as an independent civilising power. It was one result in the long process of evolution that has quickened the development of the whole race of man. If Burke, who seemed to be a friend to the Americans, was a bitter opponent of the French, it was because his Conservative mind, Liberal in its tendencies, sought to avert in one case the revolution that he dreaded, and sought in the other case to suppress a revolution that had broken out, and might possibly involve a struggle to secure great change by violence in his own country.

The thin volume published at Kilmarnock in 1786 revealed to the world in Robert Burns a lyrical poet and satirist of the first order, who found time later, amid the troubles of a short and stormy life, to fashion from his heart such love-songs as the world had never heard. William Cowper in his *Task* (published in 1784) said of the

towers of the Bastille that there was not an English heart that would not leap to hear that they were fallen. When they felt hearts of young poets in England did leap. William Wordsworth—then a youth of nineteen—conceived the high ideal that was sought by many who set loose the passions of the ignorant, and hoped within the lifetime of a generation to lift to its full height the race of man. He found his way to France, even took some part in the work of revolution; grieved over its failure, because his young spirit had seen heaven where Edmund Burke saw hell: the younger and the older man being alike sincere, alike inevitably drawn by bias of their minds to their appointed sides in the great controversy. The failure of the revolution did not fill Wordsworth with despair. While still cheishing his aspiration towards what Tennyson afterwards called a 'crowning race of man,' he came to feel that the way to such a race was long, since no state could be better than the citizens of which it is composed. But with unbroken hope he set himself to teach through verse the strength that grows out of the simple lives of men.

Thomas Campbell's *Pleasures of Hope*, in the last year but one of the 18th century, was a testament of hope left by the 18th century to the 19th. Wordsworth's *Excursion* in 1814, the year before Waterloo, was a poetical foreshadowing of the work of individual development into which the 19th century should grow. In its own time it was little understood. The tumult of the revolutionary spirit was in Byron; its pure ideal was in Shelley; its practical outcome was in Wordsworth; and a breath of health passed wherever Walter Scott's novels were read. Open expression of the reaction against Latin-English and the diction encouraged by the period of French influence was in Wordsworth's defence by preface and appendix of the style of the *Lyrical Ballads*, first published in 1798. He argued, and he acted upon his belief, that there is no separate book language; that the best thoughts are best expressed in a selection of the words in ordinary use. Again and again he laid stress on the word 'selection.' He was misapprehended, and gave some little cause for misapprehension by a defiant use in his poems of words and phrases which his better judgment, when the critical war was over and his cause had triumphed, led him afterwards to alter.

The impulse out of which Scott's poetry and Scott's novels grew it is usual to term Romanticism, as its most essential element was a revolt from the severity of classical form alike in choice and treatment of subjects for poetic expression. It was a revolt towards a more emotional and fearless expression of the relations of the human soul to the mystery and romance of the world around it. The vivid directness and imaginative power of Percy's *Ballads* (1765) gave a rude shock to the dull didactics of the 18th century, and the imitative work of the young Chatterton also revealed what influence our earlier poetry could effect upon a capable imagination. Cowper and Burns revealed the capacity for poetic expression of simple, natural language, and the earliest creations of Blake's strange spiritual genius foreshadowed a romantic revival in literature and art, which was to give us in the poetry of Coleridge, Shelley, Keats, and Rossetti almost the greatest poetic triumphs of the next century. Scott's romance was a direct issue of romanticism, and a host of imitators, under the mighty spell of the same impulses that made our greatest novelist, carried reverence for the past to strange ends in literature, art, and even religion. Charles Lamb turned 17th-century models to the best use, and disclosed the riches of the earlier drama. Not the least gain has been that

revival of interest in English literature and language, which has revolutionised the modern study of our tongue and created anew an audience for Chaucer, for the lesser Elizabethans, and even, as time went on, for *Gawain and the Green Knight*, for *The Owl and the Nightingale*, and for Cynewulf. Englishmen have awoken to the fact that they possess a native literature infinitely richer in quality and larger in quantity than any people in the world.

The past was studied and the future battled for with independent energy. Above all things truth must be found. History stood more and more pledged to an accurate inquiry into the trustworthiness of all its facts. Every statement must be traced to its original authority; that ascertained, let each man reason on it as he would. Greek history was restudied by Grote and Thirlwall; Roman, by Merivale; the history of the Jews and of Latin Christianity by Milman; the history of England by Macaulay, Freeman, Stubbs, Froude, Brewer, Gardiner, Green. Buckle and Leckie studied history and theorised upon it. The *Edinburgh Review* (1802) and the *Quarterly* (1809) inaugurated a new era of criticism. Science made wonderful advance both in knowledge and in its application, as Francis Bacon would have it applied, to enlargement of the dominion of man. It not only abounded in results of accurate research, but developed a large power of generalisation founded upon patient experiment, by which especially Charles Darwin influenced 19th-century thought.

In church questions there was the same advance of fearlessness in the inquiry after truth, and the same strenuous endeavour to make truth bear fruit within the lives of men. Every tendency of religious thought had its faithful representative in Whately, Keble, Pusey, Newman, Dr Arnold, Maurice, Dean Stanley, Canon Liddon, Dr Martineau, and many more. The periodical press opened a free plain for ready encounter of all forms of thought in honest grapple with each other. George Henry Lewes in 1865 established the *Fortnightly Review* for the free conflict of opposite opinions within the lists of a single journal. This good example was followed promptly, in 1866, by the establishment of the *Contemporary Review*; and the *Nineteenth Century* appeared in 1877. With the increase of reading power, the novel of the 19th century took the place occupied in the 16th by the drama. Women among the novelists came to the front in literature as earnest helpers to a better day, and novels came to be used for study of the deepest problems of the time. Miss Somerville in science, Miss Browning in poetry, the Brontës and George Eliot in fiction, marked the advance from days when, with few exceptions, only men took part in the mind-labour of successive generations. The civilising power of the highest literature was diffused by the energies of vigorous and earnest men, William and Robert Chambers, Charles Knight, and others. Side by side with the free literature of England, a sister literature has grown in America which adds its forces to our own. The volume of the mighty stream of English literature has increased into an expanse that can be shown here by no more than a vague suggestion of its breadth and the direction of its flow. Our last great period in English literature is marked especially by the variety of forms in which all writers who obtained a large hearing dwell on individual fidelity to duty, in a life that is sincere and simple, as the one way to the highest possible for man. It was so in all the writings of Thomas Carlyle, of Dickens, of Thackeray, of George Eliot, of Matthew Arnold, and of Robert Louis Stevenson. It was so in Alfred Tennyson, whose *Idylls of the King* figure King Arthur throughout as Conscience, the king within the human breast. It was so in all

the writings of Robert Browning, who waxes by many forms of dramatic expression against the vague ideal: and who represents the poet in his highest utterances, as he is throughout all literature, the voice of the worker when he feels most deeply the meaning of his work.

Tennyson's death left English literature in a headless state. But new forces were at work among the survivors—Meredith and Swinburne, Hardy and Biddes—and amidst the uncomfortable artificiality of the *fin de siècle* time new prophets were arising who became dominant a little later. Technique was studied. French, Russian, Irish, and Norwegian influences were felt in novel, short story, poetry, and drama. The war of science and religion drew towards its close. Evolution in its triumph was transformed. Through Butler and Nietzsche and Bergson the individual was related anew to the race and to the activity of the universe. Psychologists explored the hidden regions of his mind. Instincts became better known, less feared, and more respected. Man, like the universe, was found to be less simple than the old orthodoxies had chosen to think. Meanwhile, the humanitarian movement was ripening in democracy and social conscience. The consequences in literature of these changes in the spirit of the time are manifold.

American literature is dealt with under UNITED STATES, and there are paragraphs under AUSTRALIA and CANADA on the literature of those great British dominions. Scottish literature is treated at SCOTLAND. There are separate articles on BIOGRAPHY, the DRAMA, LETTERS, NOVELS, NEWSPAPERS, PERIODICALS, POETRY, ROMANTICISM; and the subject of English literature may be further studied in the articles devoted to the several authors named above, and to many others whom in such a sketch it is impossible to include.

Phila. 1859-71); Thomas Arnold's *Manual of English Literature* (1862); Hippolyte Taine's *Histoire de la Littérature Anglaise* (4 vols. 1863-64; translated by H. van Laun, 1871); William Minto's *Manual of English Prose Literature* (1872); A. W. Ward's *History of English Dramatic Literature to the Death of Queen Anne* (2 vols. 1875); Henry Morley's *First Sketch of English Literature* (1878; enlarged in 1886), and *English Writers* (10 vols. 1887-94); Stopford Brooke's *Primer of English Literature* (1880); Richard Wulker's *Grundriss zur Geschichte der angelsächsischen Literatur* (1885); Bernhard ten Brink's *Geschichte der englischen Literatur* (1877-88; trans. 1883-94); Bierbaum's *Manual of English Literature* (1883); Schofield, *English Literature from the Norman Conquest to Chaucer* (1906); *The Cambridge History of English Literature*, edited by Ward and Waller (1907 et seq.); Perry's *English Literature in the 13th Century* (New York, 1883); Hettner's *Englische Literatur* (6th ed. 1894); Korting's *Geschichte der englischen Literatur* (1887); Scherer's *Essays on English Literature* (trans. 1892); Leslie Stephen's *Hours in a Library* (1874; new ed. 1892); Stopford Brooke's *History of Early English Literature to the Accession of King Alfred* (2 vols. 1892); George Saintsbury's *Elizabethan Literature* (1888), *Specimens of English Prose* (1885), *Seventeenth-century Lyrics* (1892), *Essays in English Literature* (1891), and *Nineteenth-century Literature* (1896); Gosse's *From Shakespeare to Pope* (1885), *Literature of the Eighteenth Century* (1889), and *Jacobean Poets* (1894); Henry Morley's *Library of English Literature* (5 vols. 1876-82); Chambers's *Cyclopædia of English Literature* (2 vols. 1842; new ed. 3 vols. 1901-3); Ward's *English Poets* (vols. i. to iv. 1880; vol. v. 1918); Craik's *English Prose Selections* (4 vols. 1892-94); Cour-

thope's *History of English Poetry* (1895-1910); Garnett and Gosse, *English Literature: an Illustrated Record* (4 vols. 1903-4); the 'Handbooks of English Literature,' edited by Hales, and including *The Age of Pope* by Dennis (1894), *The Age of Dryden* by Garnett (1896), and *The Age of Wordsworth* by Herford (1897); Jusserand's *The English Novel in the Time of Shakespeare* (trans. 1888), and *Literary History of the English People* (trans. 1895, et seq.).

English River. (1) an estuary on the west side of Delagoa Bay; (2) another name for the Churchill River (q.v.).

Englishry. With the Norman conquerors of England, 'Englishry,' like 'Jewry,' was a term of contempt. In cases of murder, the hundred was punished, unless it could make a 'presentment of Englishry,' showing that the person slain belonged to the conquered race; and this invidious race-privilege was not abolished till the reign of Edward III.

Engrailed, a line composed of semi-circular indentations. See HERALDRY.

Engraving, in the strictest sense of the word, is the art of scratching or incising marks or figures upon tablets of any hard substance. Certain forms of the art—such as decorative engraving for purely ornamental purposes upon metal, engraved writing upon tablets for the purpose of record, gem-engraving for the production of signets, cameo-engraving, &c.—are of extreme antiquity. But, in its more especial and restricted sense, the word engraving is understood to designate the cutting or incising of designs upon metal plates or blocks of wood, for the purpose of printing impressions from them in ink upon paper, or other similar substance. Engravings of this sort are divided into the two broad classes of engravings on metal, in which the lines to be printed are sunk or incised, and engravings on wood, in which the lines to be printed appear in relief, the wood between them being cut away. In the former the plate, having been inked and wiped on the surface, retains the ink only in its hollowed lines, from which it is conveyed to the paper by the pressure of the printing-press; whereas in the latter only the elevated portion of the surface of the block is inked by means of a roller, and being subjected to the press, it prints as a raised type. [WOOD-ENGRAVING is fully described under its specific heading; here we deal only with *Engraving upon Metal*.]

The metal most commonly used for engraving has been copper; but during the 19th century steel came to be largely employed on account of its hardness, which enables it to resist the wear of printing, and to throw off a far larger number of unimpaired impressions than could possibly be obtained from a copper plate. Steel, however, is less readily engraved upon than copper, and so is apt to yield a less free and artistic result; and, by means of a modern discovery, the surfaces of copper plates can now be protected by an extremely thin coating of steel deposited by galvanic action, which enables them to yield a large number of excellent impressions without being worn. Zinc plates have also been employed to some extent for etchings, especially by Seymour Haden, a very eminent 'painter-etcher,' who liked the 'fat,' picturesque, and varied line which this metal yields when bitten by the acid.

The earliest of the impressions taken from engraved plates are those most valued by connoisseurs, on account of their sharpness, clearness, and richness, qualities which are gradually lost as the surface of the metal becomes worn by repeated printing. The term 'working proofs' indicates trial impressions printed by engravers for their own use, to test the state of their work during its progress. 'Artist's proofs' are those bearing the signature of the painter or engraver, or of both,

which is held to guarantee the quality of the impression. 'Remark proofs' have a small design etched in the margin of the plates. 'Proofs before letters' are those thrown off before the printed titling, &c. has been added; and 'open letter proofs' are those in which the letters of the title are in outline.

THE PROCESSES OF ENGRAVING ON METAL.

Line-engraving.—The chief instrument of the line-engraver is the burin or graver, a small bar of steel, usually in the form of a quadrangular prism, pointed at one end, and with the other fixed in a rounded wooden handle. This instrument is held between the engraver's forefinger and thumb, which direct the motion of the point as it is pushed forward by the pressure of the palm of the hand on the wooden handle, and incises, upon the plate of polished metal placed beneath it, a line proportionate in breadth and depth to the amount of pressure used and the angle at which the point is applied, the metal being lifted clean out of the furrow in a long strip or shaving. In this manner the design is inscribed upon the plate: and, in printing, the plate is inked, its smooth surface is then wiped clean, so as to leave the ink remaining only in the incised lines, from which it is removed to paper by being passed through the printing-press.

Etching.—In this process a polished metal plate is coated with a thin transparent surface or 'ground' impervious to the action of acid. For this purpose a composition of white wax, gum-mastic, and asphaltum is usually employed, inclosed in a ball of silk. When this ball is applied to the heated surface of the plate, the ground melts and exudes through the cloth, and is spread evenly over the metal by means of a pad of cotton-wool covered with silk, termed a 'dabber.' The plate is then exposed to the smoke of wax tapers till it becomes of a uniform black colour, which enables the etched line, disclosing the shining metal, to be visible on its surface. Upon this plate, so prepared, the design is drawn with an 'etching-needle,' a sharp steel point fitted in a handle, and held like a pencil in the artist's hand. This needle removes the impervious ground where it is applied, disclosing lines of the bare metal, which are ready to be acted upon by the acid. The back of the plate having been protected by an application of Brunswick black, it is placed in the 'acid-bath,' a flat tray filled with a mordant, usually composed of nitric acid diluted with an equal volume of water, which attacks and corrodes the metal in the lines that have been exposed to its action by the needle. After sufficient time has been allowed for the palest lines of the subject to be bitten, the plate is removed from the bath; these lines are covered with a 'stopping-out varnish' of Brunswick-black, applied with a brush, which protects them from further action of the acid; and the plate is returned to the bath, which attacks the lines still exposed. This process is repeated as often as necessary to produce the desired variety in depth of the various lines of the design. When the biting is completed, the plate is finally removed from the bath, the 'ground' is cleaned off by means of turpentine, and the design appears incised on the metal. The plate is then inked and printed in a manner similar to that employed in a plate engraved with the burin, those lines which have been longest exposed to the acid printing darkest, as they are the deepest and retain most ink. Much also can be done towards obtaining an artistic result by leaving a small coating of the ink on certain parts of the smooth surface of the plate, this film of ink printing as a delicate tint. If it should be found that the lines are too shallow, the plate may be regrounded by

means of a roller charged with the 'ground' being passed over the plate. This coats the level surface with the impervious 'ground,' but leaves the incised lines free, so that they may be again subjected to the action of the acid in the bath.

During modern times various new methods of etching, and modifications of the process described above, have been introduced. These will be found clearly and fully described in P. G. Hamerton's *Etcher's Handbook*. In particular, a process for drawing the subject while the plate is exposed to the acid was invented and much employed by Seymour Haden. He prepared the metal plate as above, and placed it in a shallow bath filled with a mordant composed of hydrochloric acid, chlorate of potash, and water. The subject is then drawn with the needle, the lines intended to be darkest being those first laid, so as to be longest exposed to the action of the acid.

It should be noticed that, while the early line-engravers worked with the burin alone, etching is combined with burin-work in most modern line-engravings; the subject being usually sketched with the etching-needle and bitten with acid, and the freer portions of foliage, &c. being also executed in a similar manner. 'Dry-point' is frequently employed in finishing the more delicate portions of line-engravings. The dry-point is an etching-needle sharpened in a particular way, and employed to scratch lines upon the bare metal. Unlike the burin, it does not cut a clean furrow out of the plate, but throws up the metal that it displaces in a ridge or 'bur,' which in printing yields a rich velvety blackness. When employed as an adjunct to line-engraving, this 'bur' is removed with the 'scraper;' and so treated, dry-point yields an extremely delicate line, very useful in finishing line-engravings and etchings. A 'ruling-machine' is also employed in producing the parallel lines representing flat skies in line-engravings.

Soft-ground Etching.—The metal plate is coated with ordinary etching-ground mixed with tallow, and a sheet of thin paper, with a certain degree of grain or texture in it, is stretched over the plate. The design is then drawn upon the upper surface of this paper with a hard black-lead pencil. On the paper being removed, it carries off adhering to its lower surface a portion of the etching-ground where pressure has been applied by the pencil-lines, exposing the metal of the plate, which is then bitten with acid, cleaned, and printed from, in the same manner as an ordinary etching. The impressions yielded by this process resemble a pencil-drawing or a lithograph.

Mezzotint-engraving.—This method differs from all other processes of metal engraving in that, while other engravers work from light to shade, and each line which they draw prints as a dark, the mezzotinter works from dark to light, and each touch which he adds to his plate prints as a light. Mezzotint-plates are prepared by the action of a kind of chisel, termed a 'cradle' or 'rocking-tool,' which passing over its surface roughens it, raising a 'bur' of innumerable small metal points, so that if the plate were then inked and printed it would yield an impression of a uniform black. The engraver, having traced his subject on the plate, proceeds to smooth the surface by removing the 'bur' with a scraper, in proportion as he wishes to introduce light into his design; the bur being left untouched in the darkest shadows, partially removed in the half-lights, and wholly cleaned away in the high lights, in which the surface is perfectly smoothed, and brought to a high polish by means of the 'burnisher.' In modern mezzotint-plates, etching and work in stipple are frequently introduced, in a mistaken effort to obviate that

softness and indefiniteness which is a characteristic of this method.

Aquatint-engraving.—In this process the polished metal plate is covered with a solution of resinous gum dissolved in spirits of wine. The spirit evaporates, leaving the resin deposited in minute granulations on the metal surface. The design is then transferred to the metal, and the plate is bitten in a bath of diluted nitric acid, which corrodes the portions left exposed between the grains of resin. The darkest parts of the design are longest exposed to the action of the mordant, the lighter parts being successively protected by a series of 'stoppings-out,' consisting of oxide of bismuth and turpentine varnish applied with a brush in a manner similar to that employed in the 'stopping-out' of an ordinary etching. The impressions produced resemble those yielded by mezzotint, both processes working by *spaces* and not by *lines*.

Chalk or Stipple Engraving.—The metal plate is coated with an ordinary etching-ground, and the subject is drawn upon it by means of a succession of small dots produced by the point of the etching-needle. The plate is then bitten in the usual way with acid, which corrodes the metal at the points uncovered by the needle; and it is afterwards finished by dots, applied with the point of the etching-needle or burin on the bare metal.

Mechanical and Photographic Process.—Engraving in recent times has suffered much from the rivalry of photographic and mechanical substitutes. The most important of these is known as photogravure or heliogravure. The beauty of the work produced by means of this process, in the reproduction of paintings, of drawings in monochrome made for the purpose, and of photographs direct from nature, has raised it to a position in which it bids fair, at no very distant date, to supersede engraving altogether; except in so far as the burin is used to touch up and finish the plates so produced. The processes employed will be described under PHOTOGRAVURE.

A photo-mechanical process which is much used in the reproduction of the plates of the older engravers and etchers, and in the production of intaglio etched plates from pen drawings, has been carried to great perfection, some of the work produced by Amand-Durand of Paris being quite equal to the finest hand etchings. A *positive* photograph is taken of the drawing or engraving to be reproduced (i.e. the lines are black, the whites clear glass); this is placed over a copper plate coated with a bituminous varnish, and exposed to the light. Where the lines of the photograph have protected the varnish from the light it remains soluble, but where the light has affected it through the glass it becomes insoluble. The varnish may then be dissolved from the lines, and the copper exposed exactly as if the etching-point had been used to make the drawing on an etching-ground. It is then etched in the usual manner, as already described, and finally touched up and improved with the graver.

There are many other mechanical and photographic processes of engraving, especially for the production of relief blocks, but their connection with engraving is remote. Such of them as are not well enough known by their distinctive names will be dealt with under ILLUSTRATION.

HISTORY OF ENGRAVING ON METAL.

Line-engraving.—The practice of engraving metal plates, for the purpose of printing impressions from them with ink upon paper, originated with the German and Italian goldsmiths about the middle of the 15th century. The goldsmiths were accustomed to take proofs of the metal objects which they decorated with engraved designs, in order to test

the progress of their work; and these *uelli* (see NIELLO), or decorated plates of metal, in which the hollows were finally to be filled in with a black enamel, supplied the necessary hint as to the possibility of printing from engraved surfaces. The long-credited assertion of Vasari that the art of printing from engraved plates was invented and put into practice by Tommaso Finiguerra, a Florentine goldsmith in 1460, is not in accordance with ascertained fact. It is impossible to fix either date or discoverer of the printing process with any such precision. Finiguerra was, however, a most important pioneer in the budding art, and the *nello pax* he executed for the church of San Giovanni in Florence, now preserved in the Uffizi Gallery, and the unique impression from it in the Bibliothèque Nationale, Paris, will ever remain the most precious memorials of engraving.

Among the very earliest Italian prints are a series of ten engravings, known as the larger Vienna Passion, unique examples of which are in the Albertina Collection in Vienna, and the *Monte Santo de Dio* (1477) printed book in which engravings were used. These are the work of Antonio Bettini. The celebrated edition of Dante, with illustrations by Botticelli, follows in 1481. These are said to be engraved by Baldini, a somewhat obscure ascription. Among other early Italian line-engravers were Antonio del Pollajuolo (1429-98), who executed a few very scarce prints, showing that command of the figure for which he was celebrated as a painter; Robetta (c.1510), whose works are excellent in design, though poor in *technique*; and Andrea Mantegna (1431-1506), whose productions are distinguished by an impressive gravity and by a dignified classical feeling. Most of these engravers were themselves painters, and engraved from their own designs; but in Marc Antonio Raimondi (c.1488-c.1530) we have an engraver in the modern sense, engaged in reproducing the works of other artists. He is mainly known by his noble transcripts of the works of Raphael, in which he was aided by the master himself, who sometimes corrected his outlines upon the copper. Among the modern line-engravers of Italy may be named John Volpato (1730-1803), known chiefly by his 'School of Athens' and other plates after Raphael; Raphael Morghen (1738-1833), whose most famous plate reproduces Leonardo's 'Last Supper,' though a finer work is his rendering of Van Dyck's portrait of Francesco de Moncada; Paul Tocchi (1788-1854), celebrated for his transcripts of the frescoes by Correggio at Parma; and Louis Calamatta (1802-69), who worked much after Ingres.

Among the productions of the North we find an example of line-engraving upon metal earlier in date than any afforded by the schools of Italy. This is a 'Flagellation,' forming part of a Passion series, dated 1446, a work attributed to an engraver of Upper Germany. Among the other early German engravers are 'The Master of 1464 or of the Banderoles' and 'The Master of 1466 or of the Initials *Æ. S.*' But it is in Martin Schongauer (c.1420-c.1488) that we find the first really able and accomplished master of the German school. His admirable works—very quaint, and full of the richest decorative feeling—are extremely scarce, but they may be studied in the excellent fac-similes executed by M. Amand-Durand of Paris. Along with Schongauer may also be named Israel von Meckenlen (c.1480-1503), another prolific and excellent engraver. In Albert Dürer (1471-1528), however, we have the great master of the German school, alike in the admirably accomplished *technique* of his plates, in their nobility of design, power of draughtsmanship, and expressional qualities. Not far beneath him must be ranked Lucas van

Leyden (1494-1533), a productive and talented workman with the burin, though he was inspired by a less lofty and profound imagination, and dealt with homelier subjects than his great contemporary. At the early age of fourteen he had already produced several very accomplished plates, and he worked unceasingly, both as painter and engraver, till his death at the age of forty. Under the influence of Dürer, there sprang up a school of engravers working after their own designs. These men, distinguished by a dexterous use of the burin, and by very considerable invention and decorative skill, are known, from the small size of their plates, as 'The Little Masters.' They include Albert Altdorfer (c. 1488-1538), Jacob Binck (c. 1490-1569), Hans Sebald Beham (1500-50), Bartel Beham (1502-40), Heinrich Aldegrever (1502-c. 1555), Georg Pencz (c. 1500-50), and Hans Brosamer (c. 1485-1552). In the end of the 16th century a notable school of line-engravers arose in Holland, among the members of which Henry Goltzius (1558-1617) produced portrait-engravings of extreme delicacy and finish, and Henry Hondius (c. 1573-c. 1662) is also favourably known for plates of a similar class; while Schelte Bolswert (born c. 1536), Paul Pontius (c. 1596), Lucas Vosterman (c. 1580), Peter de Jode (1606-60), and others were members of a school which owed its rise to the influence of Rubens. Among the more modern German line-engravers are Johann Georg Wille (1715-1807), Georg Friedrich Schmidt (1712-75), and Johann Christian Friedrich Wilhelm Müller (1783-1816), known by his fine rendering of the 'Madonna di San Sisto'; all of whom worked for a time in France.

In France some of the earliest line-engravings are the illustrations to a book by Breydenbach, published at Lyons in 1488, and reproducing woodcut views published at Mainz two years previously. Noël Garnier (working up till 1540) is known by his copies from the German engravers; but in Jean Duvet (1485-1561) France first possessed an engraver of real ability. Considerably influenced by Mantegna, he produced his 'Martyrdom of St Sebastian,' and his series of 'The Apocalypse' and of 'The Amours of Henry II.,' works of considerable inventive power. He was followed by Claude Corneille (c. 1550), Jean de Gourmont (c. 1550), Jean Cousin (1501-c. 1589), Pierre Woëriot (1532), and Etienne Delaune (1519-83), an able engraver who worked after Cousin, and is also known by his graceful hunting subjects and by his series of 'The Sciences' and the 'Twelve Months.' From such men we pass to the school of Fontainebleau, formed by Rosso and Primaticcio, of which, among the engravers, the most celebrated are Antonio Fantuzzi de Trento (1508-c. 1550), Léonard Tiry (working 1540-65), René Boyvin (1530-c. 1598), and Guido Ruggieri (working about 1570), Thomas de Leu (c. 1560-1612), and Léonard Gaultier (c. 1552-1641) may be named as good engravers of portraits, leading the way to the great school of French portrait-engravers in line of the 17th century, who carried the art to the utmost conceivable perfection of which their aims and method admitted. Among these are Claude Mellan (1598-1688); Robert Nanteuil (c. 1623-78), one of the most spirited and manly engravers of that or of any time; Jean Morin (c. 1600-c. 1666); Gérard Edelinck (c. 1640-1707), a native of Antwerp, summoned to France by Colbert; Gérard Andran (1640-1703), the most able draughtsman of the school, who largely employed etching in combination with his burin-work; and Antoine Masson (1636-1700). The line-engravers of this period are seen at their highest in their portrait-subjects, which are delightfully spirited and intelligent in handling, and—being frequently, as was usually

the case with Nanteuil's work, done *ad vivum*, or from the engraver's own drawing made from the life—possess the highest interest and authenticity as direct and original portraits. Following these men come a group of portrait-engravers who were more exclusively employed in rendering the works of painters, and whose work, absolutely skilful and accomplished as it was, rendering details and reproducing textures with unexampled exactitude and variety of touch, was yet somewhat less manly, direct, and simple than that of their predecessors. Among these were Pierre Drevet the Elder (1663-1738); Pierre Drevet the Younger (1697-1739), from whom we have a superb portrait of Bossuet, after Rigaud; and Jean Daullé (1703-63). To Wille, Schmidt, and Muller we have already referred as engravers of German nationality working in France. Laurent Cars (1702-71), Nicolas de Larmessin (1684-1756), Bernard Lépicié (1699-1755), and Pierre-Louis Surugne (1717-71) produced admirably faithful transcripts from the figure-pictures of Watteau, Chardin, and other contemporary painters. Charles-Nicolas Cochin (1715-88), in addition to similar work, executed a series of valuable medallion portraits of most celebrated men of the time; and Jacques-Philippe Lebas (1707-83), Claude-Augustin Duflos (1701-84), Pierre-Philippe Choffard (c. 1729-1809), and Augustin de Saint-Aubin (1736-1807) transcribed with vivacity the vignette book-illustrations of Gravelot and Eisen. In more recent times Louis Copia (1764-99) and Barthélemy Roger (1770-1840) ably engraved the works of Prud'hon; Charles-Clement Bervic (1756-1822) was an accomplished pupil of Wille, influenced by the classical revival inaugurated by David; after whose works Pierre-Alexandre Tardieu (1756-1844), another pupil of Wille's, engraved much, though his most important plate is 'The Earl of Arundel,' after Van Dyck. Auguste Boucher-Desnoyers (1779-1857) produced many thoroughly accomplished plates, chiefly after Raphael; Achille-Louis Martinet (1806-77) and Ferdinand Gaillard (1834-87) are to be regarded as the leading engravers of their time.

Among the earliest line-engravings published in England are the copperplates in 'The Birth of Mankind' (1540), and in a translation of Vesalius's *Anatomy* (1545), the illustrations of the latter having been copied from the original woodcuts by Thomas Geminus, who was also the translator; but William Rogers (c. 1545) is usually regarded as the first English line-engraver of mark. He is best known by his full-length of Queen Elizabeth, after Oliver. Several members of the De Passe family settled in England in the middle of the 17th century; and Renold Elstracke (c. 1620) and Francis Delarm (1590) were the chief engravers of the scarce and interesting historic portraits in Holland's *Basilologia* (1618). A more important name is that of William Faithorne the Elder (1616-91)—a pupil, while in France, of Nanteuil's—among whose works is a portrait of Milton, '*ad vivum delin. et sculpsit, 1670.*' His plates lead us to those of William Hogarth (1697-1764), whose burin engraved, in a sound, honest, and straightforward fashion, many of the figure-subjects executed by his brush.

Next comes a group of far more accomplished engravers, who worked in a classic and finished, if somewhat formal manner. Among these are Sir Robert Strange (1721-92), known mainly by his transcripts from the Italian masters; William Woollett (1735-85), seen at his best when reproducing the landscapes of Claude and Richard Wilson; and William Sharp (1749-1824); while William Blake (1757-1827), a true and sensitive 'painter-engraver,' won an abiding place in the history of the art by his 'Illustrations of the Book

of Job.' The end of the 18th century and the earlier part of the 19th is distinguished by the achievements of the great school of English landscape-engravers in line founded by William Radclyffe (1780-1855), and including Robert Brandard (1805-62), J. T. Willmore (1800-63), and William Miller (1796-1882), whose admirable artistry translated with the most finished skill the subtlest cloud-effects of Turner. The vignette illustrations to Rogers's *Italy* (1830) and *Poems* (1834) are marvellous examples of the work, on a minute scale, of this school of engravers. Since the period of these men line-engraving has declined in England, the popular demand running more in the direction of etching and of various photographic reproductive processes; but within comparatively recent years we have had such accomplished burinists as G. T. Doo (1800-86), Lumb Stocks (1812-92), and C. H. Jeans (1827-79). In America, which has produced a singularly dexterous school of wood-engravers, and also several talented etchers, comparatively little of artistic worth has been done in line-engraving. Here the process has been chiefly used for book illustration, and for the reproduction of portraiture; and many of its practitioners have been artists of British nationality. For an account of American engravers, see W. S. Baker's *American Engravers and their Works* (Phila. 1875).

Etching.—Albert Durer (1471-1528), so prolific as a line-engraver and a woodcut-designer, has also the distinction of being the earliest artist who used the process of etching; but the first—and as yet unequalled—master in this department is Rembrandt (1607-69), who, alike in portrait and subject etchings and in his rarer etched landscapes, is the perfect example of what a 'painter-etcher,' an etcher working direct from nature or from his own designs, should be. Much also was done by the pupils and immediate successors of Rembrandt, by such men as Ferdinand Bol (c. 1611-81), Philip de Koninck (1619-89); and later Adriaen Janszoon van Ostade (1610-85), Cornelis Pietersz Bega (1620-64), Nicolaas Berchem (1620-83), Paul Potter (1625-54), and Renier Zeeman (born 1612) all executed etchings worthy of preservation and study. By Van Dyck's own hand (1599-1641) is a series of masterly etchings from his portraits, plates which were afterwards completed by the burins of professional engravers. Daniel Nicolaus Chodowiecki (1726-1801), a most prolific etcher, born at Danzig, and working in Berlin, is known by his admirably spirited and graceful book-illustrations. Jan Barthold Jongkind and Carel Nicolaas van 's Gravesande produced landscape-etchings in essential sympathy with the work of the early Dutchmen; and Wilhelm Unger is favourably known as an etcher from paintings.

In Claude (1600-82), an Italian working in France, we have an etcher who infused into his work with the needle much of that delicacy and tenderness of tone and atmosphere for which his work with the brush is pre-eminent; and Jacques Callot (1592-1635) was a spirited and prolific etcher of figure-subjects. During the 18th century the sound traditions of etching seem to have been forgotten, and its true capabilities forgone in France and elsewhere; and the revived practice of the art, upon correct lines, dates from about 1840, when painter-etchers like Charles Daubigny (1817-78) and Charles Jacque (1813-94) began to find, in a periodical entitled *L'Artiste*, an outlet for the plates which they had etched for mere love of the process and of its artistic possibilities. The *Gazette des Beaux Arts*, established in 1857, is also intimately associated with the revival of the art in France, as was also M. Cadart, the Paris publisher. Among the more eminent of the

modern French etchers may be named Charles Meryon (1821-68), known by his 'views' of Paris, 'views' which are also visions; Maxime Lalanne (1827-86), one of the most graceful masters of the point; Veyrassat; Félix Braquemond (1833-1914), a robust and vigorous etcher; the painter J. F. Millet, and Jules Jacquemart (1837-80), celebrated for his delicate and sensitive renderings of old jewellers' work and other precious objects of still-life, as well as for his transcripts from pictures. Alphonse Legros (1837-1911), naturalised in England, was an etcher of great but sombre power. We have here spoken mainly of the painter-etchers, but etching, of a particularly skilled and dexterous sort, has been largely employed in Paris as a freer, swifter, and less mechanical method than line-engraving for the reproduction of paintings. Among the most skilled of the French reproductive etchers are Leopold Flameng, Paul-Adolphe Rajon (1842-88), Charles Waltner, F. A. Lagnillermie, and Le Rat.

In England, the first representative etcher is Wenceslaus Hollar (1607-77), a native of Prague, brought to this country by the Earl of Arundel in 1637. He worked under the constant pressure of extreme poverty, and much that he produced was beneath his best powers; but the finest of his prints are monumental and exemplary as specimens of the art. 'People sometimes say to me, "What is it you see in Hollar?" and I always reply, "Nearly everything,"' writes Seymour Haden. During the years that succeeded Hollar, the true spirit of the process was lost sight of in Britain, as abroad; though the mere processes of the art were kept alive by their use in preparation and subordination to line-engraving, and by the practice of such etchers as Thomas Worlidge (1700-66) in England, and David Deuchar and John Kay (1742-1826) in Scotland. It was Andrew Geddes, A.R.A. (1783-1844), whose example first gave a wholesome and vigorous stimulus to the practice of the art; and, in particular, he produced some most effective work in dry-point. Such of the etchings of David Wilkie, R.A. (1785-1841), as the 'Gentleman at his Desk,' are excellent in aim and spirited in treatment; but both Geddes and Wilkie must be studied in the scarce original states of their plates, not in the much-worn issue of 1875. Turner (1775-1851) used etching with admirable power and unerring selection of line in the plates of his *Libor Studiorum*, where the light and shade was afterwards added by mezzotint, applied usually by the hand of a professional engraver. A considerable stimulus was given to the art in England by the establishment of the Etching Club, which began to publish portfolios in 1841; and still more by the publication, in 1868, of P. G. Hamerton's *Etching and Etchers*, and the establishment of the *Portfolio*, a magazine chiefly devoted to etchings, under his editorship, in 1870. The Etching Club included in its membership such able etchers as Samuel Palmer (1805-81), J. C. Hook, C. W. Cope, and Seymour Haden, an amateur who ranks with James M.N. Whistler at the very head of the painter-etchers working in England. Among the leading practitioners of the art in these days are to be reckoned Sir Frank Short, R.A., and Frank Brangwyn, R.A. A powerful group of Scottish etchers embraces William Strang, A.R.A., D. Y. Cameron, R.S.A., Muirhead Bone, and James M'Bey, all diverse, but all highly original. R. A. Macbeth is known by important transcripts from Frederick Walker and George Mason; while Mortimer Menpes has rendered 'The Banquet of the Officers of the Archers of St Adrian' of Frans Hals in the largest dry-point on record. Among the earlier of the artists who practised etching in America may be named William Dunlap (1766-1839), the historian of American

art; George L. Brown (q.v.), known by his nine 'Etchings of the Campagna, Rome' (1860); and Edwin Forbes, who, about 1876, published a portfolio of forty plates of 'Life Studies of the Great Army.' In 1866 M. Cadart of Paris established a French Etching Club in New York, which did a good deal to foster the art. The *American Art Review*, founded in 1879, during the two years of its existence afforded a means for the publication of etchings. Second only to Rembrandt in mastery of the art is to be placed Whistler, who, cosmopolitan as he was, can be claimed by America. Among the most talented of recent etchers in America may be named Frank Duveneck (1848-1919), who produced some admirable Venetian street-scenes, Otto Baecher, Henry Farrer, Joseph Pennell, Stephen Parrish, Mary Nimmo Moran, Thomas Moran, Charles Platt, and Frank Milton Armington.

Soft-ground Etching.—This process was effectively employed by John Sell Cotman (1782-1842) in his architectural subjects, by Samuel Prout (1784-1852), and by John Ruskin (q.v.) in the illustrations to the first edition of his *Seven Lamps of Architecture* (1849); but it has now been superseded by lithography, which attains similar results in a readier way, and is much less costly in printing.

Mezzotint.—The process of mezzotint was invented by an amateur, Ludwig von Siegen (born 1609, at Utrecht), an officer who held the appointment of 'Kammerjunker' to the Landgrave of Hesse-Cassel. In 1642 he forwarded to his patron a portrait of his mother, the Dowager Landgravine of Hesse, as the first-fruits of his newly-discovered process, stating, in the letter which accompanied it, that 'how this work was done, no copperplate-engraver or artist can explain or imagine.' In 1654, after having executed other plates in the same manner, Von Siegen visited Brussels, and there came into contact with Prince Rupert (1619-82), who had already been practising etching, and to him, for the first time, the inventor disclosed his process. It was adopted by the prince, who was assisted by Wallerant Vaillant (1623-77), and was afterwards practised by Theodore Caspar von Fuerstenberg, one of whose plates is dated 1656; Johann Thomas of Ypres, who is stated to have acquired the art at Frankfort; Abraham Blooteling (1634-c.1695), an admirable engraver of portraits, who worked for a time in England; Gerard Valck (1626-c.1720); and by many of the leading Dutch painters and engravers of the century. During the 18th century mezzotint-engraving declined in Holland, and, indeed, on the Continent generally, though Jacques Christoffe Le Blon (born 1670 at Frankfort, died 1741 at Paris) devised a process for printing mezzotints by means of which various colours of ink appeared in each impression. The art was to some extent revived in Vienna, about 1780, by Jacobo, who had studied in London under the great English mezzotinters of the period; and, in the same city, Johann Peter Pichler (1765-1806) executed some admirable plates, particularly his transcripts from the flower-pieces of Van Huysum.

In France we have mezzotint-plates by J. Van der Bruggen (born 1649, at Brussels), dated from Paris as early as 1681. Sebastian Barras (born c.1680 at Aix; died 1710), Isaac Sarabat (working 1695-1701), and Bernard Picart (1673-1733) are other mezzotint-engravers who worked in France; but here the process was comparatively little used on account of the great excellence of the French line-engravers.

It was, however, in England that the art was most extensively and successfully practised, as is indicated by one of the phrases used on the Continent to designate mezzotint-engraving, *la*

manière anglaise. The process was introduced in 1660 into England by Prince Rupert, whose method is described in Evelyn's *Sculptura, or the Art of Chalcography* (1662). He executed some fifteen plates, among which the chief are the 'Great Executioner' and the 'Standard-bearer.' Sir Christopher Wren (1631-1723) and John Evelyn (1620-1706) have been believed, on rather insufficient evidence, to have practised the art. William Sherwin's plate of Charles II. is dated 1669; Francis Place (1650-1728) scraped a few portraits, including one of Charles I., free in style and delicate in gradation; Isaac Beckett (1653-1719), and particularly John Smith the Elder (1652-1742), worked much after the portraits of Kneller; and John Faber the Younger (born in Holland, 1684; died in London, 1756) engraved series of 'The Beauties of Hampton Court' and 'The Members of the Kit-Cat Club' after the same artist, transcribed the portraits of many minor portrait-painters of the time, and also engraved many subject-pictures, one of the finest being a mezzotint from Frans Hals's 'Man playing the Guitar' (1754). Richard Earlom (1743-1822) is seen at his highest in his mezzotints from Dutch flower-pictures, prints which are unrivalled for delicacy; and among his other works are his reproductions, in combined etching and mezzotint, of Claude's *Liber Veritatis* drawings. We have now reached the perfect time of the art in England, the period of the great school of mezzotinters who reproduced with splendid power the works of Reynolds and his contemporaries, with whose style of painting, with whose broad generalising touch, the method of mezzotint is in most essential sympathy. Among the greatest of these men are James M'Ardell (1710-65), by whose prints Reynolds said 'I shall be immortalised,' Edward Fisher (1730-85), James Watson (1740-90), John Jones (1740-1810), J. Raphael Smith (1750-1812), Valentine Green (1739-1813), William Dickinson (1746-1823), S. W. Reynolds (1773 or 1774-1835), and Charles Turner (1773-1857). The mezzotint-prints executed after Sir Joshua alone include the work of about sixty different engravers. Some of these men, such as Charles Turner and S. W. Reynolds, took part in the plates of the *Liber Studiorum* of J. M. W. Turner (himself an accomplished mezzotinter, as certain plates of that series attest), and engraved the portraits of Raeburn, works especially adapted for reproduction by their method; and William Ward (1766-1826) scraped a few splendid prints after another Scottish painter, Andrew Geddes. The latest and most effective development of pure mezzotint in landscape includes the renderings by Thomas G. Lupton (1791-1873) of Turner's 'Ports' and 'Rivers' of England, and the transcripts by David Lucas (1802-81) from the works of Constable, a series executed, like the *Liber Studiorum* of Turner, under the closest supervision of the painter; who, however, did not, like Turner, himself use the scraper, though he longed to do so, writing to his engraver, 'How I wish I could scratch and tear away with your tools on the steel.' On account of the larger number of impressions which could be printed from them, steel plates had already been introduced by the mezzotinters, but these being scraped with somewhat less facility than the copper plates formerly employed, tended much to the deterioration of the art and to the loss of its especial qualities of freedom and painter-like breadth, especially when the mezzotint work was largely supplemented, as was now commonly the case, by the burin, and by etching and stipple-engraving. By means of this modern method engravers of first-rate power, such as Samuel Cousins (1801-87), were capable of producing attractive and excellent plates; but in the hands of inferior workmen the

results attained by this bastard combination of various processes were pitifully inartistic. One of the first inaugurators of a distinct revival of the art upon the old legitimate lines of pure mezzotinting upon copper was Joseph Josey, who engraved very sympathetically Whistler's 'Thomas Carlyle' and 'Portrait of the Artist's Mother.' William Campbell (1855-87) executed several excellent mezzotints after Burne-Jones. A powerful impetus towards right technical methods was given by Sir Hubert von Herkomer (born 1849 in Bavaria; died 1914), and among his pupils D. Wehrschmidt (Velesmith) and William Henderson have engraved excellently after Holl's portraits, and Gerald Robinson is favourably known by his delicate transcript from Van Dyck's bust portrait of Henrietta Maria in the royal collection. Seymour Haden added mezzotint to the later states of his powerful etching from Turner's 'Calais Pier'; and Sir F. Short, in addition to original work, has produced, in combined etching and mezzotint, some admirable copies from Turner's *Liber Studiorum*. Mezzotint was the first form of engraving practised in America, Peter Pelham (c. 1684-1751) having removed from London and settled in Boston before 1727, the year in which he published, from his own painting, a mezzotint of the Rev. Cotton Mather, which was followed by various other portraits of eminent Americans. Among the other mezzotint engravers of America may be named Thomas B. Welch (c. 1814-74), and John Sartain (born in London, 1808; died 1897).

Aquatint-engraving.—This method is believed to have been invented by Jean-Claude-Richard de Saint-Non (1730-1804), a French draughtsman and etcher who studied in Italy, and to have been communicated by him to Jean Baptiste Le Prince (1733-81), a native of Metz working in Paris, who sold the secret to the Hon. Charles Greville. By him it was disclosed to Paul Sandby, who was the first to practise the method in England, using it to reproduce his Welsh landscapes, and carrying it to great perfection in his 'Views in the Encampments in the Parks' (1780). It was also employed in Scotland by David Allan (1744-98), who engraved in this manner his illustrations to Ramsay's *Gentle Shepherd* (1788). F. C. Lewis (1779-1856), the best aquatint-engraver of his time, is known by his reproductions of the drawings of Claude and of Lawrence; and he added the aquatint light-and-shade to the first plate of Turner's *Liber Studiorum*, mezzotint being employed for this purpose in the rest of the subjects of the series. Catherine Prestel (died in London, 1794), a German, executed some fine plates in combined etching and aquatint; and in Spain Goya (1746-1828) employed a similar union of processes in the wild and bizarre plates which he produced. Aquatint is now little used, but Brunet-Debaines adopted it with accomplished skill in his renderings of the landscapes of Turner.

Chalk or Stipple Engraving.—Jean Charles François (1717-69) is said to have been the first engraver to employ this process, and for its discovery he received a pension of 600 francs from the French king, along with the title of 'Graveur des desseins du Cabinet du Roi.' He used the method chiefly for the reproduction of drawings in crayons, for which it has since been very popular until the discovery of Lithography (q.v.) and of Photography (q.v.), by which such fac-similes can more accurately and readily be produced. He was followed by Giles de Marteau the Elder (1722), another able engraver. The process was introduced into England by William Wynne Ryland (born 1732; executed for forgery, 1783), who worked in this method after drawings by the old masters and the designs of Angelica Kauffman; but the most celebrated of

the stipple-engravers working in England was an Italian, Francesco Bartolozzi (1725-1815). In America some good portrait engraving in stipple was produced by David Edwin (1776-1841), an Englishman who studied in his native country and in Holland, and by Ion B. Forrest (1814-70), a Scotsman trained in London.

Works dealing with the history and practice of engraving are very numerous. In Dr W. H. Willshire's *Introduction to the Study and Collection of Ancient Prints* (2d ed. 1877), a useful book of reference, will be found a list of nearly a hundred works denoted to engraving. A. M. Hind's *History of Engraving and Etching* (new ed. 1923) is exhaustive and thoroughgoing. J. H. Slater's *Engravings and their Value* (5th ed. 1921) is valuable for biographies. For an account of technical processes, the student may consult T. H. Fielding's *Art of Engraving* (1841), P. G. Hamerton's *Etcher's Handbook* (1871), the various editions of his *Etching and Etchers*, and his *Graphic Arts* (1882). *Le Peintre-Graveur* of Adam Bartsch (Vienna, 1803-21, and Leip. 1854), with its supplements by J. D. Passavant (6 vols. Leip. 1860-64), and A. P. F. Robert-Dumesnil's *Le Peintre-Graveur Français* (8 vols. Paris, 1835-50), and the 11 volumes of its continuation by Georges Duplessis, are the standard catalogues of old prints. Among the other works that may be named are W. Y. Otley's *Early History of Engraving* (2 vols. 1816); Georges Duplessis's *Histoire de la Gravure en France* (1861), *Les Merveilles de la Gravure* (1869), and *Histoire de la Gravure* (1880); and Bryan's *Dictionary of Painters and Engravers* (edited by George C. Williamson, 4 vols. Lond. 1903-6); and there are separate monographs and catalogues for the more important engravers. See also *The Print Collector's Handbook*, by A. Whitman (Lond. 1901); Bourcard's *Graveurs et Gravures* (Paris, 1910); S. R. Koehler, *Etching, its Progress and History* (1886); Herkomer, *Etching and Mezzotint Engraving* (1892); Wedmore, *Etching in England* (1895); Pennell, *Etchers and Etching* (1920); Lumsden, *Art of Etching* (1925); and the valuable series of fac-similes by M. Amand-Durand of Paris.

Engrossing, a term used to describe the conduct of those who buy up merchandise in large quantities to obtain command of the market. This was formerly an offence punishable by law and by municipal regulations; as were also the offences of forestalling (buying merchandise on its way to market) and badgering or regrating (buying to sell again at an unduly enhanced price). The old laws in restraint of trade were not found to work well. So far from making the necessities of life cheap as they were intended to do, they discouraged producers and traders, and so made prices abnormally high. The English statutes on the subject were therefore repealed in 1772, and the offences of engrossing, &c. were finally abolished, both in England and in Scotland, in 1844. In the United States, engrossing is a common-law offence; and the constitutions of several states declare that monopolies are 'contrary to the genius of true government'; but with the development of modern commerce these restrictions became obsolete. See ASSOCIATIONS, TRUSTS, AND CARTELS.

Engrossing a Deed means the writing it out in full and regular form on parchment or paper for signature. The person who engrosses is usually a law-stationer or clerk. In Scotland, the corresponding term is 'extending a deed,' and till 1874 it was necessary that the person extending the deed should be named in the testing clause. See DEED.

Enharmmonic, originally the name of one of the three Greek scales, is now applied to music constructed on a scale containing intervals less than a semitone—e.g. where the difference is recognised between G \sharp and Ab, or D \sharp and Eb. On the old organ built by 'Father' Smith for the Temple Church in London these notes had separate keys. But in modern keyed instruments, tuned, as they now universally are, in equal temperament, these

notes are represented by the same sound; and the possibility is afforded of enharmonic *modulation*, in which a chord belonging to one key is, by a change merely of its notation, made the means of passing into another key. The chords commonly used in this change are the diminished seventh, or equivocal chord, which may be written in four different ways, and (less often) the dominant seventh, which may be changed into the German sixth. See MUSIC.

Enkhuizen, a town of North Holland, one of the 'dead cities of the Zuider Zee,' 35 miles NNE. of Amsterdam. It once sent out 400 ships to the herring-fishery, and had 40,000 inhabitants; but its harbour has gradually silted up. It was the first town to throw off the Spanish yoke (1572), and in 1625 was Paul Potter's birthplace. Pop. 8000.

Enlistment in Britain was, until 1802, in the hands of middlemen, who received a commission for their trouble. Since that year it has been managed by the adjutant-general's department. Formerly, a soldier enlisted for life, and could never look forward to retiring on a pension while still possessed of a fair share of health and strength. This was changed in 1847 by an act which limited the term of enlistment to 10 years for infantry, and to 12 for cavalry or artillery. A soldier could then either quit the army without pension, or re-engage for the remainder of 21 years, at the expiration of which time he was entitled to a pension for life; and in 1868 twopence a day was added to the pay of every soldier so re-engaged. This system was not compatible with the formation of trained reserves, with which to bring the army to fighting strength in the event of war, and in consequence the 'Army Enlistment Act' of 1870 was passed. Under this act men still enlist for 12 years, but with the understanding that 7 years or less shall be passed with the colours, and the remainder in the reserve. This is known as 'short service;' and a reserve of trained soldiers has thus been formed who are liable to be called back into army service if great emergency arises during their reserve service. The Army Act of 1881 substantially improved the procedure of enlistment, and has been since amended. There is now no risk that the man shall be improperly influenced, as by liquor; and the recruiter's 'shilling,' which used to compel the man to enlist, is abolished. The law of enlistment is laid down in the Army Act (see ARMY DISCIPLINE). The man is given by the recruiter a notice paper, which tells him particulars of service, and the questions he will be asked, and time and place at which he is to appear. Follows the primary military examination by the recruiting officer, who asks him the authorised questions from the attestation paper, and obtains a reference as to character. This is followed by the medical examination. The man is now taken before the 'attesting officer' or a magistrate; his answers are entered on the paper, he takes the oath of allegiance, the paper is signed by him, by a witness, and by the attester. The Recruit (q.v.) next appears before the approving officer, and only after that is he fully enlisted. A false answer on attestation is punishable under the Army Act. At any time within three months, unless the Army Reserve (q.v.) has been called out, the recruit can buy his discharge. An apprentice can be claimed by his master at any time within a month, subject to certain provisos. Special reserve men (see under ARMY) enlist for 6 years, and then have the option of continuing for spells of 4 years, up to the age of 45. The territorial force are *enlisted*—not *enrolled*, as the volunteers were—and have thus become subject to military law whenever on duty. See DESERTION, DISCHARGE, FOREIGN ENLISTMENT ACT, and RECRUIT; and for the manning of the navy, see NAVY.

Enna. See CASTROGIOVANNI.

Ennemoser, JOSEPH, a medico-philosophic writer, was born in 1787 at Hintersee, in the Tyrol, and commenced his medical studies at Innsbruck in 1806. On the rising of the Tyrolese against the French in 1809 he followed Andreas Hofer as his secretary; at the close of the war he went to Eilangen, and subsequently to Vienna, for the purpose of concluding his studies. In 1813 he raised a company of Tyrolese marksmen, who were of great service during the campaigns that followed. After the peace of Paris he finished his curriculum at Berlin, and devoted himself to the study of animal magnetism. In 1819 he was made professor of Medicine at Bonn, where he lectured until 1837; he then practised for a time at Innsbruck, but in 1841 removed to Munich, where he obtained a great reputation by the application of hypnotism as a curative power. He died 19th September 1854. Among his numerous writings *Der Magnetismus in seiner geschichtlichen Entwicklung* (Leip. 1819) is reckoned his principal work.

Ennerdale Water, a lake of Cumberland, 8 miles ESE. of Whitehaven, is fed by the Liza, descending from Great Gable by the north side of the Pillar and the Steeple, and drained by the Ehen, which runs some twelve miles west and south by Cleator and Egremont to the Irish Sea near Sellafield. The lake measures 2½ miles by ½. It stands 368 feet above sea-level; has a maximum depth of 148 feet; an average depth of 62 feet; and contains about 1978 million cubic feet of water. Wordsworth makes Ennerdale the scene of *The Brothers*.

Ennis, a municipal borough of County Clare, Ireland, on the Fergus, 25 miles NW. of Limeick, and 151 WSW. of Dublin by rail, is a neat town, with some good houses. Here are the Catholic cathedral of Killaloe diocese, a fine court-house, the Clare lunatic asylum, large flour-mills, a school founded by Erasmus Smith (1689), a column to O'Connell (1863), and a memorial to the 'Manchester Martyrs.' Till 1885 Ennis returned one member to Parliament. Pop. 5500.

Enniscorthy, a market-town of Wexford, beautifully situated on the navigable Slaney, 78 miles S. of Dublin by rail. The Roman Catholic cathedral of Ferns diocese is the principal edifice. There is a large corn-trade. The population is about 5500. Enniscorthy grew up round a castle, still entire, founded by Raymond le Gros, one of the early Anglo-Norman invaders. Cromwell took it in 1649; and the rebels from Vinegar Hill (q.v.) stormed and burned it in 1798.

Enniskillen, a municipal (till 1885, also parliamentary) borough, the capital of County Fermanagh, 87 miles WSW. of Belfast, and 117 NW. of Dublin by rail, is beautifully situated on an isle in the river between Upper and Lower Loughs Erne. Around are richly cultivated eminences and many fine mansions; whilst among its own edifices are the Protestant and Catholic churches (the latter a fine modern building), the large barracks, a lofty monument to Sir Lowry Cole, and the Royal Portora School. The chief manufactures are cutlery and straw-plait. The population is 5000. Enniskillen is famous for the victory, in 1689, of the troops of William III., under Lord Hamilton, over a superior force of James II., under Lord Galmoy. The banners taken in the battle of the Boyne hang in the town-hall. The regiment of Enniskilleners, or 6th Dragoons, was first instituted from the brave defenders of the town.

Ennius, one of the earliest Roman poets, the father of the Roman Epos, was born at Rudia, in Calabria, about 240 B.C., and was probably of

Greek extraction. He is said to have served in the wars, and to have risen to the rank of a centurion. In Sardinia he became acquainted with Cato the Elder, and returned with him to Rome when about the age of thirty-eight. Here he gained for himself the friendship of the most eminent men, among them Scipio Africanus the Elder, and attained (what was then exceedingly rare in the case of an alien) to the rank of a Roman citizen. He supported himself in a decent but humble manner by instructing some young Romans of distinguished families in the Greek language and literature, his accurate knowledge of which explains the influence he had on the development of the Latin tongue. He died when he had attained the age of seventy, about 170 B.C. His remains were interred in the tomb of the Scipios, and his bust was placed among those of that great family. Ennius tried his powers in almost every species of poetry, and although his language and versification are rough and unpolished, these defects are fully compensated by the energy of his expressions and the fire of his poetry. His poems were highly esteemed by Cicero, Horace, and Virgil: the last, indeed, frequently introduces whole lines from the poetry of Ennius into his own compositions, and owes him the whole structure of certain episodes. His memory seems to have been lovingly cherished by his countrymen: *Noster Ennius*, 'Our Ennius,' they used to call him. Of his tragedies, comedies, satires, and particularly of his *Annales*, an epos in 18 books, only fragments are extant. What adds to our regret is that it is believed his whole works were extant as late as the 13th century. The fragments have been edited by Vahlen (1854), Müller (1885), and Dr Ethel Stuart (*Annales*, 1925); the dramatic fragments by Ribbeck (1873). See Lucian Müller, *Quintus Ennius* (1884); Ribbeck, *Römische Tragödie* (1875); Sellar, *Roman Poets of the Republic* (2d ed. 1881); Simcox, *Latin Literature* (1882); Norden, *Ennius und Vergilius* (1915).

Enns, a river of Austria, rises at the northern base of a branch of the Noric Alps in the land of Salzburg, 12 miles S. of Radstadt, and flows 190 miles (only the last 20 navigable) in a general northerly direction, till it joins the Danube a few miles below Linz. Its chief affluents are the Salza and the Steier. From ancient times the Enns has formed the boundary between Upper Austria (Ober der Enns) and Lower Austria (Unter der Enns). Having mostly a rapid fall, it is chiefly important from the valuable water-power which it supplies.

Enoch, 'the seventh from Adam' (Jude, xiv.), 'walked with God' (Gen. v. 21-24), and, after a life of 365 years, 'was not, for God took him.' It is probable that the number of the years of Enoch was in some way connected with the number of days in the solar year. Partly from this, and partly from the interpretation of his name (Heb. *Hanōkḥ*) as 'initiated,' arose the later Jewish legend that Enoch had invented writing, arithmetic, astrology, and astronomy. He was held to have predicted the flood, and to be the possessor, through revelation, of the knowledge of all mysteries in heaven and earth. By the Arabs he is called *Idris* ('the experienced' or 'learned').—For the Glasgow 'St Enoch,' a corruption of 'St Thenaw,' the name given by St Serf to St Kentigern's mother, see the article KENTIGERN.

Enoch, BOOK OF. There are two books ascribed to Enoch in Jewish apocalyptic literature, the one known as 'The Book of Enoch,' the other as 'The Book of the Secrets of Enoch.' The Book of Enoch itself is a library rather than a volume, and includes at least five different documents,

182

written at different periods, and dealing with different subjects. The first book (chaps. i.-xxxvi.) was written about 170 B.C. It contains an interesting theory as to the origin of sin, which it explains as due to the lust of angels for the daughters of men (Gen. vi. 1-8). The second book from a chronological point of view consists of chaps. lxxxiii.-xc., and belongs to the Maccabean period (166-161 B.C.). The third book (chaps. xci.-civ.) is usually dated between 134 and 95 B.C. It represents the position of the Pharisees of the period, and finds the solution of the problem of evil in a belief in the future life. The fourth book (chaps. xxxvii.-lxxi.) belongs to the first half of the 1st century B.C., but its specific date cannot be determined. It is distinguished for its development of the conception of the Messiah, whom it portrays as 'the Son of Man.' The fifth book (chaps. lxxii.-lxxxii.)—the Book of Celestial Physics, as it is called—is an attempt to establish a Hebrew calendar to supersede the pagan calendars in vogue at the time. There can be little doubt that New Testament theology owes a very considerable debt to the Book of Enoch, especially to its Messianic conceptions, which are in advance of the ideas on the subject found elsewhere in this literature. The Book of Enoch exists in its entirety only in an Ethiopic version.

The Book of the Secrets of Enoch is a comparatively recent discovery, having been brought to light in a Slavonic version in 1892. It was probably written at Alexandria between 1 and 50 A.D. The book describes the ascension of Enoch and his voyage through the seven heavens. Each of these heavens is described at length. The second heaven, for instance, is the abode of the fallen angels, and the prisoners awaiting eternal judgment. The third is the place of Paradise, the home of those 'who turn their eyes from unrighteousness and accomplish a righteous judgment.' The sixth heaven is the dwelling-place of the angels who regulate the powers of nature, and record the deeds of men. The seventh heaven contains the throne of God surrounded by a multitude of the heavenly hosts. The book throws no little light on the conception of the heavens in the New Testament.

The best edition of these books is found in the *Oxford Apocrypha and Pseudepigrapha* (1913).

Enos (the ancient *Ainos*), a seaport, on a rocky isthmus near the mouth of the Maritza, about 35 miles NW. of Gallipoli. It has some trade in wool, cotton, leather, wax, &c., but its harbour is now choked with sand. Pop. 8000, principally Greeks.

Enriquez Gómez, ANTONIO (properly ENRIQUEZ DE PAZ), a Spanish poet, the son of a baptised Portuguese Jew, was born at Segovia, early in the 17th century. He entered the army in his twentieth year, and rose to the rank of captain; but in 1636 fled to Amsterdam, and, having there professed the Jewish faith, was in 1660 burned in effigy at a Seville auto-da-fé. The date of his death is not known. For his twenty-two comedies, of which some passed as Calderon's, and his poems, see Ticknor's *History of Spanish Literature*.

En'schede, a town of Holland in the province of Overijssel, 30 miles ENE. of Zutphen. Rebuilt since its destruction by fire in 1862, it has large yarn and cotton mills. Pop. 41,500.

Ensign was, until 1871, the title given to officers of the lowest commissioned rank in the British infantry (the corresponding rank in the cavalry being Cornet), because they carried the regimental Colours (q.v.) or ensign. Formerly this was a duty attended with much danger when in action, and considered highly honourable; but colours are no longer taken into battle, and officers

of the rank of ensigns and cornets are now called second lieutenants. See also FLAG.

Ensilage. See SILAGE.

Enstatite, an important rock-forming mineral. It is essentially an anhydrous silicate of magnesia, but usually contains also small percentages of alumina and ferrous oxide. It belongs to the pyroxene group of minerals.

Entablature, that part of a design in classic architecture which surmounts the Columns (q.v.), and rests upon the capitals. It is usually about two diameters of the column in height, and is divided in every style of classical architecture into three parts—architrave, frieze, and cornice. These parts vary in their relative proportions in different styles. In Doric architecture, for example, if the entablature be divided into eight equal parts, two of these form the height of the architrave, three that of the frieze, and three that of the cornice. In the other styles, the relative proportions are as three, three, and four.

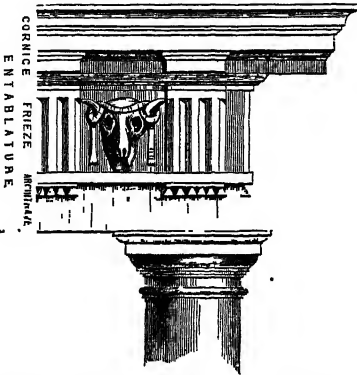

Fig. 1.—Example of Doric Entablature.

The *Architrave* is the horizontal portion which rests immediately upon the abacus of the column. It is usually ornamented with horizontal mouldings, with flat spaces or *fasciæ* between. The upper moulding always projects farther than the others, so as to throw off the rain. This moulding varies in different styles. In Doric (fig. 1) it is a plain square projection, with small pendants or *guttae* under the triglyphs. In the other styles it is generally an ogee or talon moulding. These mouldings are frequently enriched with leaf ornaments, and in very florid designs the *fasciæ* are also enriched.

The *Frieze* is the middle portion of the entablature, between the top of the architrave and the bed of the cornice. In the Doric style it is ornamented with triglyphs or slight projections, divided by angular grooves into three parts. The spaces between the triglyphs (called metopes) are square, and are either plain or enriched, either with figure-sculpture, as in the Parthenon, or with bulls' heads, pateræ, or other ornaments. In the other styles the frieze is never cut into portions, but is either left quite plain or ornamented with figure-sculpture or scroll-work. The former is most usual in Greek art, the latter in Roman. In late Roman works the frieze is sometimes *swelled* or made to project with a curve.

The *Cornice* forms the upper portion of the entablature. It is divided into several parts. The lower moulding or mouldings resting on the frieze are called the bed-mouldings, the lower member of the upper projecting part is called the Corona (q.v.), and between the two there are frequently introduced

modillions and dentil bands. The bed-moulding is generally of an oval or echinus form, and is frequently enriched with the egg and tongue or leaf ornaments. The upper moulding of the corona is generally of a *cyma recta* form (see COLUMN, fig. 1), and is often ornamented with lions' heads. These represent the openings through which the rain was at first led off from the roof-gutters cut in the top of this moulding, and were retained as ornaments after their original use was discontinued. The corona projects well over the frieze and architrave, and protects them from rain, while at the same time, by its broad shadow, it gives repose and variety of effect to the building. The *soffit*, or under side of the corona, is frequently panelled and ornamented with pateræ.

Origin.—The component parts of the entablature are said, with some appearance of truth, to owe their origin to the forms of the construction of the oldest temples. These were of wood, and were put together in the manner most natural for that material. The square beams laid across from post to post are represented by the architrave; the triglyphs of the frieze are copied from the ends of the cross-beams; the cornice is taken from the boarding which covered the rafters and ties of the roof—projected so as to throw off the rain; and the dentils and modillions show the ends of the rafters left uncovered. It is not supposed that these features were intentionally imitated by the classic architects, but that the original wooden construction produced forms which were afterwards traditionally though unconsciously followed.

Whatever the origin of the entablature may have been, it is a remarkable fact, as connected with Greek and Roman art, how persistent the entablature was as a feature in the decoration of all classic styles. So long as buildings consisted of one story in height, this was quite natural; but after this simple system was abandoned, and when, as in Roman architecture, several series of columns and entablatures were piled one above the other—not used constructionally, but simply applied to the face of the building—the cornice, frieze, and architrave still retained their places and proportions. In the revived Roman art of the 16th century the entablature was used in a manner still further removed from its original purpose (fig. 2).

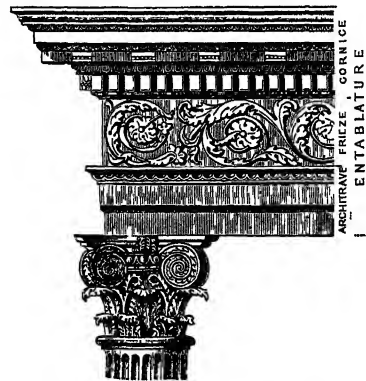

Fig. 2.—Example of Composite Entablature.

The strict proportions of the various parts were entirely lost sight of. The frieze was increased in height, so as to admit of small windows, to light the Entresol (q.v.) or mezzanine, and in the French and English forms of the Renaissance the various members become still more attenuated and altered from the original design (see RENAISSANCE). But in no modification of classic

architecture, however debased, is the entablature wanting. The architrave, frieze, and cornice are essential portions of every classic design.

Entada, a genus of leguminous climbing shrubs (sub-order Mimoseae) remarkable for their great pods. The egg-sized seeds of *E. gyalobrium* are carried by the Gulf Stream not only to the Canaries, but to Nova Zembla, where their occurrence suggested the name of 'Chestnut Bay.'

Entail. The desire to preserve in our own family land which we have either inherited or acquired appears to be inherent in the human mind. Arrangements of this nature were not known to primitive peoples, among whom land descended according to strict customary rules which could not be altered by the act of an individual owner. In some of the ancient Greek states owners of property were permitted to name successors to their estates, and to appoint a substitute who should take the estate on the failure of him first named. The substitute so appointed was permitted to succeed on the death of the institute (as he was called) without leaving issue or without alienating the estate. Under the Roman law the practice of settling land upon a series of heirs, by means of *Fideicommissa* (q.v.), grew up, and was sanctioned by the state. These deeds, in their early form, contained merely a substitution of heirs. But by the later law a much fuller form of settlement was admitted, whereby the estate was protected from every sort of alienation. The limitation to a particular line of descent, the prohibition to alienate or burden with debt, and the still more peculiar feature of the declaration of forfeiture in case of non-compliance are to be found in both forms. There are, however, two points in which the Roman law differed from modern laws of entail. It did not recognise the right of Primogeniture (q.v.), and after the legislation of Justinian the limitation of the deed was restricted to four generations. For the right of primogeniture, as recognised in deeds of entail, we are indebted to the feudal law. That system, which has united with the civil law to form a basis for the codes of modern Europe, did not, in its original form, recognise the right of a holder of land to alienate his feudal benefice, or even to alter the succession, because on the failure of heirs the feu returned to the superior. But the right of the eldest son to represent his father, both in the duties and privileges of the fief, if not an original principle of the system, was universally recognised in the days of its greatest power.

In *England*, the Saxons seem to have prohibited the alienation of lands by those who had succeeded to them under condition that they should not alienate. The law of primogeniture was not recognised. But after the Norman Conquest feudal grants were often made 'to A and the heirs of his body,' or 'to A and his heirs, if he shall have heirs of his body.' The estate thus given was regarded as a fee-simple conditional; on the birth of an heir of his body, A would acquire the fee; and, like other owners in fee after the 13th century, he was at liberty to alienate. To prevent this, the feudal lords obtained the enactment of the statute *De Donis*, by which it was directed that the fee given with the words above quoted should in all cases descend according to the form of the gift; so that, in the case supposed, A would not have a fee-simple, an estate to him and his heirs-general, which he was free to alienate, but a fee-tail—i.e. a fee *taillé* or cut down, which he could not alienate so as to bar the rights of his issue. Under the statute, lands might be settled in tail, or in tail male, or in tail special—i.e. on a man and the heirs of his body by a particular wife.

A settlement in tail special was somewhat analogous to a settlement in Frankmarriage (q.v.).

The restraints on alienation thus imposed were contrary to sound policy, and the courts permitted tenants in tail to bar or cut off the entail; a tenant in possession was permitted to bar all rights of other persons, and so to turn his own estate into a fee-simple. From the time of Edward IV. down to 1833 this was effected by means of fictitious actions, called Fines and Recoveries; for these cumbrous and expensive forms the 3 and 4 Will. IV. chap. 74 substitutes a simple disentailing deed. A strict settlement of land usually begins with an estate for life to an existing person, followed by an estate tail to his son. When the donee of the estate tail comes into possession, he can disentail and alienate at his own discretion. If not in possession, he can dispose of his own rights and those of his issue; but he cannot destroy the entail, so as to bar remaindemen and reversioners, and turn his estate into a fee-simple, unless with the consent of the 'protector of the settlement,' who is usually the tenant for life. An estate tail is a freehold of a limited description. Tenant in tail in possession may commit Waste (q.v.). Formerly, an estate tail was not liable to the debts of the tenant, but by 1 and 2 Vict. chap. 110 this restriction has been removed. Copyhold lands have been held not to fall under the operation of the statute *De Donis*. A limitation, therefore, which in a freehold creates an estate tail, in copyhold lands creates a fee-simple conditional, according to the old common law, except where the custom of the manor is to the contrary. But, by trust-conveyances, copyhold estates may be settled in the same way as freeholds. The rules against Perpetuities (q.v.) prevent property from being tied up for an indefinite period; but family estates are usually re-settled by owners and heirs of entail in each generation. Lord Cairns's Settled Land Act, 1882, has given to tenants for life absolute power of sale upon notice to the trustees of the settlement, and without petition to the court, the price being invested for the persons interested under the settlement. By a series of statutes in *England*, tenants for life have also received large powers of managing and improving their estates.

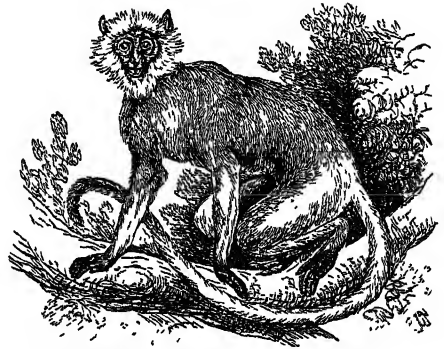

In *Scotland*, as in *England*, entails appear first to have taken their rise from the feudal usages, and from the Roman law, the forms of which were closely followed by conveyancers. It has been observed by Lord Kames that, while the feudal system was in its vigour, every estate was in fact entailed, because no proprietor had any power to alter the order of the succession. But when the stricter feudal principles gave way, and the power of alienating land began to be recognised, the holders of estates sought by deed to secure in their own families the lands which they possessed. The form first adopted for this purpose was the simple destination, whereby the estate was simply limited to a particular series of heirs, without prohibition to alienate, or declaration of forfeiture for contravention of the will of the grantor. In this form the deed must have resembled the early *English* entails. The feudal law of primogeniture having been received as a principle of common law, the estate would naturally descend from father to son in the line indicated by the deed. But, as it was held that those succeeding under this deed were not restrained from alienating, the practice of adding prohibitory clauses was introduced. Entails in this form were held to bind the heir from granting gratuitous alienations; but he was not restrained from selling the estate, or burdening it with debt. Early in the 17th century a further addition was made to the form of the deed by the introduction of irritant and resolute

clauses—i.e. clauses declaring the act of alienation to be null, and to infer the forfeiture of the estate. The form thus adopted, which resembles closely the form of the Roman deed already noticed, was fortified by a decision of the Court of Session on the Stormonth entail in 1662, holding that an estate so protected could not be attached by creditors. This decision created much difference of opinion amongst lawyers as to the power of the grantor thus to protect an estate from the onerous act of the heir. In consequence the famous Scotch Entail Act, 1685, chap. 22, was passed, by which it was enacted that an estate conveyed by a deed fortified by prohibitory, irritant, and resolute clauses, and recorded in a particular register, should be effectually secured in the line of destination. This act has always been most strictly viewed by Scottish lawyers; and entails which have been found deficient in any of the prescribed requisites have been regarded by the courts as utterly ineffectual. The operation of the old entail act was found, notwithstanding, to be of the most oppressive character. Statutes were in consequence passed from time to time, empowering heirs of entail to exercise larger powers of ownership than could be granted under the Act of 1685, and to make provisions for their families. Chief among these were the Montgomery, the Aberdeen, and the Rosebery Acts. At length, by 11 and 12 Vict. chap. 36 (known as the Rutherford Act), the power of fettering lands by a strict entail has been finally destroyed. By this act, heirs under an existing entail may disentail, with the consent of certain heirs next in succession; and in all entails made after 1st August 1848, and also in old entails where the heir in possession was born since 1st August 1848, the heir of entail in possession may, by means of a simple deed of disentail, free his estate from the restrictions of the entail. A statute in 1875 gave the heir in possession larger powers of permanent improvement and the right of buying out the interest of the next heirs at a compulsory valuation; and the Entail (Scotland) Act, 1882, gave further powers of disentailing in the case of entails made since 1848, and in all cases a practically absolute power of sale to be exercised on petition to the court, the price being invested for behoof of the heirs of entail. From statistics returned to parliament in 1892, it appeared that disentailed land was rapidly re-entailed in Scotland.

In *America*, before the Revolution, the English law as to estates tail prevailed. But in the United States, the law of entails has been gradually abandoned by the several states; and property can now be fettered to a limited extent only, by means of executory Devises (see *WILL*). In *Germany*, family settlements of a very strict character, and 'private laws' regulating the descent of property in certain noble houses, are permitted by the laws of some of the states which form the German empire. In *France*, the power of creating entails has varied much at different periods, from the right to make a perpetual entail, which appears to have been the original principle, to a limitation to four, and at one time to two degrees. But by the Code Napoléon, arts. 896-897, entails are now absolutely prohibited. In *Spain*, also, entails, till then permitted under certain restrictions, were entirely abolished by the Cortes in 1820. Thus it will be seen that the right of securing land in a particular family, which commends itself to the natural feelings, has been found so oppressive in operation, and so injurious to the public interest, that, after an existence of more than 600 years, it has been practically discarded almost simultaneously by the general consent of modern nations.

Entebbe, the administrative headquarters of Uganda, is on the NW. shore of Victoria Nyanza.

Entellus Monkey, or **HANUMĀN** (*Semnopithecus Entellus*), the most sacred monkey of the Hindus, worshipped as half divine, and regarded as the host of ancestral souls. The body is 4½ feet in length, from ashy-gray to dirty yellow in colour; the face is dark, with bushy grayish-white whiskers; and the tail is longer than the body. Entellus

Entellus Monkey (*Semnopithecus Entellus*).

monkeys live in troops, are noisy and quarrelsome, and do much mischief near towns and plantations, but are nevertheless revered and petted. They are sometimes identified with the Langur. For the mythology, see **HANUMAN**.

Entente Cordiale (Fr., 'cordial understanding'), a term which originated, according to Littré, in the French chamber of deputies in 1840-41. Since the Anglo-French Convention of 1904 (about Egypt, Morocco, and Newfoundland) the term has been used especially to denote the friendly relation, short of formal alliance, between France and Great Britain; extended later to France's ally Russia, and so forming a 'Triple Entente,' balancing the triple alliance of Germany, Austria-Hungary, and Italy, until the outbreak of war in 1914.—Dr Beneš's 'Little Entente' between Czechoslovakia and Yugoslavia (1920) was joined by Rumania in 1921.

Enteric Fever. See **TYPHOID FEVER**.

Enteritis (Gr. *enteron*, 'an intestine'), inflammation of the bowels, is a name at the present day reserved for inflammation affecting the inner mucous coat of the bowel, the term Peritonitis (q.v.) being applied to inflammation of the outer coat. Inflammations of special parts receive the name of colitis, appendicitis, &c. Enteritis forms the chief feature of some infective diseases due to the growth of special organisms, such as typhoid fever, dysentery, cholera. It may be acute, when, if severe, it is a dangerous condition often associated with inflammation of the stomach (gastro-enteritis). This acute type occurs in the summer diarrhoea of young children (see **DIARRHŒA**) and in outbreaks of food-poisoning, and a very violent form of enteritis is brought on by the action of irritant poisons like arsenic. In some persons enteritis of a milder type comes on after exposure to cold and damp. Occasionally enteritis is chronic, as in cases following dysentery or caused by tuberculosis. The chief symptom of enteritis is diarrhoea, with griping pain, in severer cases also vomiting and rise of temperature with, it may be, delirium, and later collapse and failure of the heart's action. In treatment the food should be lessened as much as possible, even withheld for a day or two, in order to minimise the irritation of the bowel; rest in bed with warmth to the abdomen is essential.

In the *Lower Animals*.—Among horses, inflam-

mation of the bowels generally results from some error of diet, such as a long fast followed by a large, hastily devoured meal, such as raw potatoes, boiled or indigestible and easily fermentable food, or large draughts of water at improper times. When thus produced, it is frequently preceded by colic, affects chiefly the mucous coat of the large intestines, and often runs its course in from eight to twelve hours. With increasing fever and restlessness, the pulse soon rises to 90 or upwards, and, unlike what obtains in colic, continues throughout considerably above the natural standard of 40 beats per minute. The pain is great, but the animal, unless delirious, instead of recklessly throwing himself about, as in colic, gets up and lies down cautiously. Respiration is quickened, the bowels torpid. Cold sweats, stupor, and occasionally delirium, precede death. When connected with, or occurring as a sequel to influenza, laminitis, and other complaints, the small intestines are as much affected as the large, and the peritoneal as well as the mucous coat of the bowels. When the animal is seen early, whilst the pulse is still clear and distinct, and not above 70°, and the legs and ears warm, bloodletting is useful, as it relieves the overloaded vessels, and prevents that extravasation of blood which speedily becomes poured out in the interior of the bowels. This disease should be treated as follows: Care should be taken not to further irritate the bowels by the administration of purgative or even aperient medicines, as the supposed constipation is due to the bowels having lost their function—loss of function being one of the phenomena of inflammation—and not to a dry condition of their contents. Anodynes and sedatives, as laudanum in two-ounce doses, or belladonna extract in two or three drachm doses, should be repeated every two hours until pain is relieved. Morphia and atropia subcutaneously injected are also now largely used by veterinarians with fomentations to the surface of the abdomen and an occasional clyster of warm water. No attempt should be made to force the bowels to action after apparent recovery, or the inflammation may be re-excited.

Enteritis in cattle is mostly produced by coarse wet pasture, acrid or poisonous plants, bad water, and overdriving. The symptoms are fever and thirst, a quick but rather weak pulse, restless twitching up of the hind limbs, tenderness of the belly, moaning and grinding of the teeth, and torpidity of the bowels. Calves generally die in three or four days, other cattle in a week or nine days. Enteritis in sheep mostly occurs in cold, exposed localities, and where flocks are subjected to great privations or improper feeding. The symptoms and treatment resemble those of cattle. The treatment prescribed for the horse is applicable to the cow, the doses being one-third larger.

Enteropneusta, a class of worm-like animals, including *Balanoglossus* (q.v.) and *Cephalodiscus* (q.v.). It is of great zoological importance because of the characters in which the members resemble vertebrates. The name, literally 'gut-breathers,' refers to the paired respiratory pouches opening from the front part of the alimentary canal.

Entomology (Gr. *entomon*, 'an insect,' *logos*, 'a discourse'), the study of Insects (q.v.).

Entomostraca, a general name for the lower orders of Crustacea, including Phyllopods, Ostracods, Copepods, and Cirripedes. See CRUSTACEA.

Entophytes. See PARASITIC PLANTS, PLANTS (DISEASES OF), SYMBIOSIS; also FUNGI.

Entozoa, internal animal parasites such as Tapeworms (q.v.). See PARASITIC ANIMALS.

Entr'acte, in Music, is an instrumental piece, composed in the form of a short symphony or overture, to be performed between the acts of a play.

Entrecasteaux. See D'ENTRECASTEAUX.

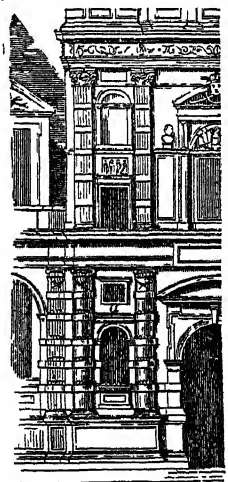

Entre Douro e Minho, or, as it is frequently called, MINHO, a province of Portugal, in the extreme north-west of the country, is bounded on the N. by the river Minho, and on the S. by the river Douro. Area, 2800 sq. m.; population, 1,300,000. It has been called the Paradise of Portugal. The climate is agreeable and healthy. The chief productions are wine, oil, flax, maize, wheat, barley, oats, and vegetables. Wine is shipped largely at Oporto, the capital. Along the coast are numerous fisheries, at which great numbers find employment. The province of Minho consists of three districts, Braga, Vianna, and Oporto.

Entrenchments are the earthen parapets thrown up to give cover against the enemy's fire, and the ditches or trenches from which the earth is obtained for them. They may be either of the most hasty or of the most deliberate kind. Of the former class are the various patterns of shelter-trench, in which the men stand, kneel, or lie in the trench 1 foot 6 inches to 3 feet deep, and fire over a parapet 1 foot 6 inches to 2 feet 9 inches above the ground-level, and also the different saps used for siege purposes, in which the trench forms the roadway towards the fortress attacked, and the parapet gives cover to the troops using it. The deliberate kind include all field and permanent works, having a thick parapet of considerable height, over which the men fire, and by which they are protected, while the ditch from which the earth for the parapet has been dug forms an obstacle in its front (see FORTIFICATION). The term is also used for any fence, building, wood, or other natural cover that has been scientifically prepared for defence.

Entre Rios ('between rivers'), a province of the Argentine Republic, in the 'Mesopotamia Argentina,' between the Paraná and the Uruguay (whence its name). Estimated area, 20,000 sq. m.; population, about 416,000. The country is chiefly pastoral, but an increasing proportion is being put under cultivation, a wide area being now devoted to maize and wheat. The province is fertile and well watered, being even subject, in the south, to annual floods; nevertheless, the climate is very healthy. Lime and gypsum are worked. Cattle-raising and the making of meat-extract are important industries. The capital is Paraná (q.v.).

Entresol is a low story between two main stories of a building, generally above the first story, but in London most usually between the ground-floor and the first story. *Mezzanine* is another name for the entresol, as also for its low, broad windows.

Entropion, or ENTROPION (Gr. *en*, 'in,' and *trepō*, 'I turn'), inversion of the edge of the eyelid, consequent either on loss of substance on its inner surface, or on excessive action of the muscle (the orbicularis palpebrarum) which closes the lids. The eyelashes are turned inwards and rub upon the globe during the movements of the lids, producing much irritation, and sometimes opacity of the cornea. Temporary relief may be obtained by plucking out the misdirected lashes by the roots;

a, Entresol.

but the radical cure of severe entropium requires a careful adaptation of the surgeon's art to the circumstances of the particular case, and should not be attempted by unskilled hands. The most common cause of entropium is granular conjunctivitis. See EYE (DISEASES OF).

Entry, FORCIBLE. See FORCIBLE ENTRY.

Envelope, a wrapping, covering, or enclosing medium. Thus, the perianth of a flower is called its floral envelope; in a comet the nebulous covering of its head is the envelope; and in mathematics the locus of the ultimate intersection of a series of curves is termed an envelope. As a manufactured article, an envelope is a paper bag or pocket for containing letters, stationery, and other postal matter. Previous to 1840 envelopes were little known or used, though in Paris in 1653 a postal delivery was instituted, for which prepaid envelopes were used. Bishop Burnet, writing in 1714, mentions the use of an envelope for a letter; and Dean Swift, in his *Grub Street Poets*, writes:

No letter in an envelope
Could give him more delight.

In 1839 Rowland Hill, whose postal reforms were largely instrumental in their introduction, spoke of 'the little bags called envelopes.' With the establishment of prepaid postage in the United Kingdom on 1st May 1840, the adhesive stamp and an envelope with an allegorical design by Mulready, R.A., were simultaneously put on sale. The convenient stamp quickly displaced the Mulready envelope in public favour; a vast supply prepared for sale had to be destroyed, and the Mulready envelope has become a philatelic curiosity. It was not till towards 1850 that the use of envelopes became common. Now their manufacture is a huge industry, in which much ingenious machinery is employed.

The early forms of envelopes were made and folded by hand, and for exceptional forms, required in small quantities, hand-making still is practised. But for standard sizes, machines turning out as many as 100,000 per working day are exclusively employed. The first efficient envelope-making machine was patented in 1844 by Warren de la Rue and Edwin Hill. That machine differed from those now in use only in not gumming and folding the envelope in one operation. In modern practice a pile of 500 sheets or more, if the paper is thin, is cut at one operation by the steel blades of a punching-machine into blanks, of the shape and size of the required envelope. The adhesive solution used in the gumming process consists of gum arabic or dextrine, and is applied to the overlaps of the blanks by the gum-picker fed with the solution, as printing-ink is supplied to inking-rollers. In the folding-box the two sides and the lower flaps are pressed together and sealed. The envelope is next carried forward on an endless chain, and in its progress the gum on the upper flap is dried. Various devices for fastening envelopes are in use. For the carrying of heavy articles, envelopes strengthened with a lining of calico are employed.

In the stationery trade certain standard sizes of envelopes are recognised, corresponding with the size of the paper they are meant to enclose. Square or court envelopes are prepared for single-folded correspondence paper, whilst commercial or oblong forms accommodate twice-folded sheets. Again, in the trade a distinction is made betwixt what is called envelope shapes and bag shapes, the essential difference being that in the envelope shape the upper or sealing part is on the long side, whereas in the bag shape the sealing flap is on the narrow side of the envelope. Opacity is in general a desideratum in envelope paper, an object sometimes

helped by printing lines on the inside of the paper. On the other hand, some envelopes have a panel of transparent paper through which the address shows.

Environment, a modern term for the influencing surroundings of an organism. Neither plant nor animal can be understood as a rounded-off unity; the whole life or function is made up of action and reaction between the organism and its environment. Streams of matter and energy from without preserve the relative constancy of the organism, as of a special wave-crest in the sea; while changes in the streams have their corresponding changes within. The plant or animal has obviously a strong unity of its own, but even that is in part due to ancestral welding under the hammers of the environment. It may seem, too, to vary of itself like a fountain in the air, but throughout all its rises and falls there blows the wind of the environment. The influence of outside conditions has been recognised by most naturalists from the time of Hippocrates, and is taken for granted in our everyday speech and action. There is considerable difference of opinion, however, as to the importance and degree of this influence. Thus Buffon, Treviranus, and Geoffroy St Hilaire regarded the surroundings as *directly* hammering changes on the organism; while Erasmus Darwin and Lamarck regarded internal changes as *indirect* functional results of new environment. Charles Darwin allowed a measure of truth in both these positions, but emphasised the indirect destructive action of the animate and inanimate environment in the struggle for existence. These three positions are still held, some emphasising one, others another, the majority combining the three (see EVOLUTION).

The external influences may be classified in four groups: (1) Molar or Mechanical; (2) Chemical; (3) Molecular or Physical; (4) Vital or Animate. A few instances of each kind will be given.

(1) *Molar or Mechanical Influences.*—Confined space brings about a dwarfed brood. Currents mould the sponges and corals, chisel the shells, cut up the water leaves; and the wind blows the trees out of shape. Vertical pressure may broaden out the form or produce latent life; while the very weight of structures effects many changes, from the mode of an egg's dividing to the slope of a tree's branches. On the whole, however, the mechanical hammers effect least.

(2) *Chemical Influences.*—Subtler but more potent are the influences which we group together as chemical. Good aeration—i.e. abundant oxygen—quickens development and stimulates the whole life. The 'vital combustion' is more rapid. In drought some animals become desiccated (see DESICCATION), and the Axolotl (q.v.), removed from the watery bed to less moist environment, becomes an Amblystoma. The composition of the medium seems to have a great influence on the forms and phases of simple unicellular life, and it is often very important in the case of eggs, embryos, and larvæ. Remarkable and perplexing changes may result from a slight change in the chemical composition of the sea-water. Food may be included under this group, and its influences are the greatest. To Claude Bernard the whole problem of evolution was very much a question of variations in nutrition. It is the food, to a large extent, which conditions the cyclic changes in cell-life from an active ciliated phase to a passive amoeboid or encysted one (see CELL). Parasites in their passivity illustrate a nemesis at least exaggerated by their copious nutrition. Abundant food is associated with growth and asexual multiplication; the plant sends out its runners, the plant-lice continue their rapid parthenogenesis (see APHIDES), but a check to nutrition hastens the sexual climax. C. W. Beebe caused the scarlet tanager (*Pranga erythro-*

melas) and the bobolink (*Dolichonyx oryzivorus*) to keep their breeding plumage through the year by giving them fattening food and keeping them without much exercise in dim light. According to Sutton, hypertrophy of one part over another has been the principal process in the transition from hermaphroditism to unisexuality, while Barfurth emphasises the importance of fasting as a progressive factor in evolution. From the cell-cycle to the colour of canaries' feathers, the importance of the food-factor is widely demonstrable.

(3) *Physical Influences*.—Heat stimulates growth and hastens the reproductive maturity, while cold tends to dwarf and often produces coma. Maupas increased the rate of reproduction in an Infusorian five times by an elevation of 17° C. in the temperature of the water. Dr W. H. Dallinger has described how the monads which he succeeded in educating to stand a temperature high above the usual fatal point became not a little altered at the crisis of each successive elevation. Weismann has shown how an artificial winter induces the winter colouring of a certain Butterfly (q.v.). The sunlight which kills the floating germs has a beneficial action on most organisms, very notably on plants. In some cases it seems to affect colour, and Poulton has altered the colour of his Caterpillars (q.v.) by the tint of the glass under which they lived, or has produced golden chrysalids by keeping them in gilded boxes. Electric and probably magnetic energies seem also to have influences.

(4) *Vital Influences*.—In the web of life organisms influence one another indirectly in a hundred ways, but they have likewise their direct influences. There are animate as well as inanimate 'hammers.' Sea-spiders specifically alter Hydroids, and Semper also notes the mutually influencing associations of a snail and a coral, of an Annelid and an Antipathes (a genus of Zoantharia). Crustacean parasites may very effectively alter their crustacean hosts, and internal guests have also marked results. In some cases, such as galls, insects produce individual modification in the plants they frequent.

Hundreds of cases of external influence, now on one system, now on another, are known, but few are thoroughly understood. The observation of the results is one thing, their rationale another. In a general way, barring purely mechanical modifications, the influences are referable to two classes—one set increasing constructive processes, storage of energy, passivity, anabolism; the other set increasing destructive processes, expenditure of energy, activity, katabolism.

The susceptibility of organisms to outside influences is very varied. Simple and young forms are evidently more in the grip of external circumstances than are complex and adult organisms. The cell, the seedling, the child, are more impressionable than the worm, the tree, the man. Passive forms also, like sponges and algae, corals and trees, are much more under the tyranny of surroundings than active organisms with devices at command for parry or escape. The vegetative system, again, is oftener affected than the reproductive.

The degrees of influence are also very varied. The dints of the environment may be deep or superficial, very direct or very remote in their results. A primary influence from without may have more than one result within the organism, by starting correlated variations. The influence may remain without apparent result in the individual, and yet the nemesis may be evident in the offspring. Influences may also accumulate within the organism without any evident outcrop for a time, but at length an indirect, at first sight spontaneous, change may be the far-off result. The influence of environment in forcible distribution, in a cataclysmic destruction of local fauna, and the count-

less indirect results of changed conditions must also be kept in view.

It remains unproved that bodily modifications induced by changes in the environment can be transmitted to the offspring as such or in any representative degree (see HEREDITY). The relation between organisms and their environment remains, however, of essential importance. We must recognise the fact of the constant dependence of the living creature on its surroundings, the fact of transient individual adjustment and lasting individual modification, the fact that modifications may have secondary effects on the offspring, and the fact that environmental changes may act on the germ-plasm as variational stimuli.

See Semper's classic work, *The Natural Conditions of Existence as they affect Animal Life* (Inter. Sc. Series, 1880); T. H. Morgan, *Experimental Zoology* (1907); the articles DARWINIAN THEORY, EVOLUTION, HEREDITY, WEISMANN, and authorities there named.

Envoy, a diplomatic minister inferior to an Ambassador (q.v.). Like the latter, he receives his credentials immediately from the sovereign, though he represents not his prince's personal dignity but only his affairs. He thus ranks above the Chargé d'Affaires (q.v.). See CONSUL.

Enzeli, now PAHLEWI, on the Caspian, is the port of Reshd (q.v.).

Enzymes. See FERMENTATION.

Eoanthropus ('dawn-man'), a generic name given by Dr Smith Woodward in 1912 to a late Pliocene or early Pleistocene race of man (*Eoanthropus Dawsoni*), represented by some fragments of a skull and mandible found by Mr Charles Dawson in a gravel-pit at Piltdown, Fletching, near Lewes. A canine tooth was got in 1913; new fragments in 1915. The skull is remarkable for its extreme thickness. Owing to the fragmentary character of the remains, attempted reconstructions disagree. Sir Arthur Keith's restoration gives the Piltdown man a skull and brain of approximately the form and size of modern races. Dr Smith Woodward gives him only about two-thirds of the modern man's brain-capacity. The jaw, on the other hand, is much more ape-like. Some think it a chimpanzee's. *Eoanthropus* thus differs from the Neanderthal race, which has a more simian brain and more human jaw. We may regard the human stem as divided into four branches—*Pithecanthropus*, *Eoanthropus*, Neanderthal, and that represented by present-day man.

Eocene System, in Geology. This is the lowest or oldest series of strata included in the Tertiary division. The name Eocene (*ēos*, 'dawn,' *kainos*, 'recent') was introduced in 1830 by Lyell, whose classification of the Tertiary formations was based on the proportions of living species of molluscs which the strata contain. The oldest members of the series, containing as they do only an extremely small proportion of such recent forms (according to Lyell, 3½ per cent.), were looked upon as indicating the dawn of the existing state of the molluscan fauna. With necessary modifications, Lyell's classification has maintained its place, but the names of the various subdivisions of the Tertiary strata, first suggested by an examination of the European deposits, are now used without reference to the precise percentage of living molluscan species which the beds may chance to contain. The Eocene beds rest unconformably upon the Chalk or Cretaceous strata—hence there is a break in the succession. A movement of elevation followed upon the close of the Cretaceous period, and the sea disappeared from middle Europe. Probably the British area at this time was connected with what are now the opposite coasts of the Low Countries and

France, and considerable denudation of the later Cretaceous deposits supervened. Ere long, however, partial subsidence set in, and at the beginning of Eocene times the sea commenced to invade those regions in the south-east of England, the north of France, and the low grounds of Belgium, in which we meet with the oldest accumulations of Tertiary times.

The Eocene system, as developed in England, occurs chiefly in two districts, called respectively the London and Hampshire basins. In the north of France it forms another large basin, in the centre of which is Paris, and it likewise spreads over a considerable area in Belgium. The strata are partly of fresh-water and partly of marine and brackish-water origin, and consist principally of more or less unconsolidated sands, clays, loams, marls, &c., with which are here and there interstratified layers of limestone and lignite. Grouping the Anglo-French and Belgian strata together, we have the following succession:

	ENGLAND	FRANCE AND BELGIUM.
UPPER EOCENE	Barton Clay and Upper Bagshot Sands	Gyps marin: Sables moyens.—Wemmelian.
MIDDLE EOCENE	Bracklesham Beds: Middle Bagshot Sands.	Calcaire grossier.—Lekennian: Bruxellian.
	Lower Bagshot Sands ...	Waiting in France: Pansellian, Upper Ypresian.
	London Clay and Bognor Beds	Waiting in France.—Lower Ypresian.
	Oldhaven Beds	Not recognised.
LOWER EOCENE	Woolwich and Reading Beds.	Argile plastique: Lignites du Soissonnais.—Upper Landenian.
	Thanet Sands	Sables de Bracheux.—Lower Landenian and Heersian.

In the south of Europe the Eocene system is developed on a much larger scale. In place of the limited basins of the Anglo-French and Belgian areas we encounter a thick and widespread series of limestones and calcareous sandstones. These accumulations appear on both sides of the Mediterranean, in Spain, and in Morocco. They enter largely into the composition of the Apennines, the Alps, the Carpathians, and the Balkans; they extend through Greece, Egypt, and Asia Minor, and thence through Persia and the Himalayas to the coasts of China and Japan. The most characteristic feature of these thick calcareous beds is the occurrence in prodigious numbers of nummulites—a foraminifer. Another noteworthy feature of the Eocene system of southern Europe is the occurrence in the Alpine region of Bavaria of certain sandstones, &c. (locally called *Flysch*), in which appear many gigantic erratics of various crystalline rocks—the precise source of which is not known. They may possibly have been derived from the archæan masses of Bohemia. In North America the more important Eocene strata are the great lacustrine deposits of the Rocky Mountain region and the plateaus lying to the west. But marine deposits of the same age occur also along the borders of the Atlantic, the Mexican Gulf, and the Pacific.

The flora of the Eocene is represented chiefly by dicotyledonous and monocotyledonous plants, and had a prevalent Indo-Australian character. Palms, screw-pines, cypresses, and various proteaceous plants grew in England in early Eocene times, and with these were associated species of custard apple, gourd, melon, oak, walnut, magnolia, &c. Amongst the forms of later Eocene times were species of gum-tree, nettle-tree, and banksia, fan-palms and screw-pines, aroids and cacti. Evergreens were represented by laurels, cypresses, and yews, while deciduous trees were represented by species of maple, plane, willow, poplar, elm, beech, chestnut, hornbeam, walnut, fig, &c. The fauna, like the flora, is also indicative of somewhat tropical con-

ditions. Among the characteristic molluscs were species of *Conus*, *Voluta*, *Cypræa*, *Oliva*, *Nautilus*, &c. Sharks were numerous, such as *Otodus*, *Lamna*, and *Carcharodon*; and reptiles were represented by turtles, terrapins, snakes, lizards, crocodiles, and alligators. None of the great Mesozoic Saurians, however, survived into Tertiary times. Among the more remarkable birds were *Odontopteryx*, the jaws of which had tooth-like denticulations, and *Dasornis*, akin apparently to the extinct gigantic *Dinornis* of New Zealand. Early forms of modern types were also present, such as species of heron, gull, vulture, buzzard, woodcock, quail, pelican, flamingo, ibis, &c. Many of the mammals of Eocene times were remarkable for the union of characters intermediate between marsupials and carnivores. Tapir-like animals, such as *Palæotherium*, seem to have abounded. Another common form was *Anchitherium*, which had affinities to the *Palæotheres* and true horses. There were also many hog-like animals with intermediate or generalised characters, as well as transitional hornless forms of deer and antelopes. From the Eocene also come the earliest of the *Prosimiæ*—the lemuroid *Cænopithecus*, as well as ancestral forms of bats, hedgehogs, and squirrels. From the American Eocene lacustrine beds have been obtained remains of some very remarkable types. Among these are four-toed and five-toed ancestors of the horse, and *Dinoceras*, an animal as large as the elephant, furnished with three pairs of horns and two long tusk-like canines (see *DINOCERATA*). Another strange order of animals (*Tillodonts*) combined characters which are now met with in such distinct groups as the ungulates, rodents, and carnivores.

The Eocene deposits of the Anglo-French and Belgian area appear to have accumulated in an inland sea opposite the mouths of one or more great rivers. In Eocene times large areas which are now land were under water; the Mediterranean extended farther north and south than it now does, while eastwards it stretched into Asia, perhaps to the Indian Ocean. The Pyrenees, Alps, Carpathians, and Himalayas were inconspicuous heights. Since the Nummulitic sea washed their base, they have been upheaved for thousands of feet—the old floor of that sea is now met with in the Alps at heights of over 10,000 feet, in the Himalayas at 16,500 feet.

Eolians. See *ÆOLIANS*.

Eoliths, a name given by some archæologists to very early and roughly broken Flint Implements (q.v.), or natural flints assumed to have been used as weapons by human beings at an earlier date than the oldest and rudest palæoliths. See *ANTHROPOLOGY*, *STONE AGE*.

Éon de Beaumont, CHARLES GENEVIÈVE TIMOTHÉE D', known as the *Chevalier d'Éon*, was born at Tonnerre, in Burgundy, in 1728, studied law, and became an advocate. He attracted the notice of the Prince de Conti by some political writings; and in 1755 was introduced by the latter to Louis XV., who employed him in diplomatic missions to Russia and Austria. After serving a short time in the army, not without distinction, he was sent to London in 1762 as secretary of embassy, and shortly after was made minister plenipotentiary. On the death of Louis XV., the French ministry deemed it prudent to recall him, as they were afraid he might betray their secrets to the English government, which made him brilliant offers. After much negotiation, Éon consented to surrender certain compromising papers, and submit to the condition imposed by Louis XVI. of wearing feminine garb, which he had often before assumed as a disguise, and which he now wore till his death. The doubt as to his sex, fostered by his parents in his childhood, was maintained, for reasons which can only

be conjectured, till the end of his life. On the outbreak of the French Revolution, while he was again in London, he offered his services to the French nation, but nothing came of his offer. He maintained himself by giving lessons in fencing till in 1796 he was disabled by an accidental wound, after which he was reduced to great destitution. He died 21st May 1810, when an examination of his remains by a surgeon settled the question of his male sex, and put an end to the curiosity of the English public. His writings appeared at Amsterdam (1774) under the title of *Loisirs du Chevalier d'Éon*. The *Mémoires* which bear his name are not genuine. See Telfer, *The Chevalier d'Éon de Beaumont* (1885-96); Langton's *D. N. B.* article (1888); a monograph by Vitzetly (1895), and the Life by Homberg and Jousselein (1904; Eng. trans. 1911).

Eötvös, JOZSEF, BARON (1813-71), Hungarian author, was born and died at Budapest. He became an advocate in 1833, but soon devoting himself to literature, published two comedies and a tragedy, a work on prison reform, his first great novel, *The Carthusian* (1838-41), *The Village Notary* (1846; Eng. trans. 1850), &c. In the revolution of 1848 Eötvös was Minister of Public Instruction, as again under Andrássy (1867) after three years of exile.

Eozoön, the name given in 1864 by Sir William Dawson to an assumed organism (apparently a foraminifer) whose supposed remains constitute reefs of rock in the Archæan System in Canada; but the belief that it is inorganic steadily gained ground, and is now universally accepted.

Epacridaceæ, a small order of heath-like shrubs or small trees, usually indeed reckoned as the Australian sub-order of Ericaceæ, from which they are chiefly distinguished by the epipetalous stamens destitute of the peculiar specialisations of anther-dehiscence or appendages. Many species—e.g. *Epacris grandiflora*, &c., are cultivated in our greenhouses along with the heaths proper. A few produce edible berries. See CRANBERRY.

Epacts (Gr., 'additions'), in Ecclesiastical Chronology, a set of nineteen numbers used for fixing the date of Easter and other church festivals, by indicating the age of the moon at the beginning of each civil year in the lunar Cycle (q.v.). At the reformation of the calendar in 1582 it was found that the Golden Numbers could no longer by themselves serve the purpose of adjusting the double reckoning by lunations and by the tropical or true year; and thus, instead of adopting the more rational computation, the Roman Church devised the artificial and involved method of epacts. The main point to determine is the age of the moon (in entire days) at the beginning of each civil year, or the number of days between the end of the ecclesiastical year in December and the 1st January succeeding. Thus, subtracting 354 days (12 lunations) from 365, we should have 11 days for the first annual epact, then 22 for the year following, then 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, and 29; the series of 19 numbers being obtained in succession by adding 11, and when the sum exceeds 30, subtracting that number. This illustration, however, is simpler than any actual case, by reason of the leap-years, which require 12 to be added for the following epact, and of the fact that no lunation is exactly 30 days long. When the lunar cycle of 19 years is completed, the epacts recur again in the same order. In the Anglican reckoning, as distinguished from the Roman, it is noteworthy that the Gregorian epact for any year is the same as the Julian epact for the year preceding, owing to the coincidence that 11,

the number of days lost on the Julian account before our parliament adopted the reformed Calendar (q.v.), is also the number of days between the lunar and the solar years. The epact determines by subtraction the date of the first new moon in January; then by adding 29 and 30 alternately the successive new moons throughout the year are assigned to their respective dates. See Delambre's *Astronomie Moderne*, vol. i. 4-32.

Epaminondas, the most eminent of Theban generals and statesmen, and one of the noblest figures in Greek history, was born towards the end of the 5th century B.C. He was descended from an ancient but impoverished family, and led a retired life till his fortieth year, profiting by the instructions of Lysis the Pythagorean, an exile from Tarentum, who inspired him with enthusiasm for the elevated ideas which it was the object of his life to realise. Plutarch tells us that Epaminondas saved the life of Pelopidas in battle in 385, which was the beginning of one of the most famous friendships of antiquity. After the desperate but successful stratagem by which his fellow-citizens recovered the *Cadmeia* and expelled the Spartans (379), Epaminondas stepped forward immediately into the ranks of the patriots; and, when sent to Sparta in 371 to negotiate a peace between the two countries, displayed as much firmness and dignity as eloquence in the debate which ensued upon the question whether Thebes should ratify the treaty in the name of all Bœotia, the result of which ratification would have been equivalent to a recognition of her claim to supremacy over the Bœotian towns. To this the Lacedæmonians demurred, and the war was again resumed; Epaminondas was appointed to the chief command, and along with Pelopidas, with an army of but 6000 men, defeated twice that number of the enemy at Leuctra (371). Two years later, with Pelopidas, he marched into the Peloponnesus, and incited several of the allied tribes to fall away from Sparta. On his return to Thebes, Epaminondas was accused of having violated the laws of his country by retaining the supreme power in his hands beyond the time appointed by law, but was acquitted in consequence of his open and animated defence. In the spring of 368 the war between Thebes and Sparta was renewed with increased fury, and Epaminondas made a second and somewhat unsuccessful invasion into the Peloponnesus, receiving on his return a check from Chabrias at Corinth. To atone for this unsuccessful undertaking he advanced with 33,000 men into Arcadia, and joined battle with the main body of the enemy near Mantinea, in the year 362 B.C. Epaminondas charged at the head of his men, and broke the Spartan phalanx, but was mortally wounded in the breast by a javelin. Being told by the physicians that he would die as soon as the weapon was extracted, he waited till he heard that the Bœotians had gained the victory, then drew out the javelin with his own hand, exclaiming: 'I have lived long enough.' See his Life by Cornelius Nepos, and, in German, Baugh (1834) and Pomtow (1870).

Epaulette (from the French *épaule*) is a fringed shoulder-knot worn since 1795 by commissioned officers of the British navy, sub-lieutenants wearing one of gold lace, and other ranks two. Crowns, anchors, and stars worked in silver on the epaulette, and the size of the cords of the epaulette itself, indicate the degree of rank. Previous to the Crimean war officers of the British army wore gold epaulettes, and the men worsted ones. Many foreign nations still retain them for both naval and military officers.

Épée, CHARLES MICHEL, ABBÉ DE L', instructor of the deaf and dumb, was born at Versailles, 25th

November 1712. Taking orders, he became a preacher and canon at Troyes, but eventually, on account of his Jansenist opinions, was deprived of this office, and now lived in retirement in Paris. In 1765 he first began to occupy himself with the education of two deaf and dumb sisters; and, as he asserts, without any previous knowledge of Pereira's efforts in the cause, invented a language of signs, by which persons thus afflicted might be enabled to hold intercourse with their fellow-creatures. His attempts being crowned with success, he determined to devote his life to the subject. At his own expense he founded an institution for the deaf and dumb, which was first publicly examined in 1771, and from 1778 received an annual subsidy. It was not, however, converted into a public institution till two years after his death, which took place 23d December 1789. He wrote two or three works on his system, for an estimate of which see Hartmann's *Deafmutism* (Eng. trans. 1881). See DEAF AND DUMB.

Epeira, a genus of spiders, the type of a family called Epeiridæ, including the common Garden Spider (*Epeira diademata*). See SPIDER.

Eperies (Slovak *Prešov*), an old town of Czechoslovakia, on the Tazca, 150 miles NE. of Budapest. It is the seat of a Greek Catholic bishop, and has a college. A conflagration of 7th May 1887 destroyed 400 houses and most of the chief public buildings. It manufactures earthenware, linens, and woollens, and has some trade in corn and Tokay wine; whilst in the vicinity are the Sovai salt-works. Pop. 18,000.

Épernay, a town in the French department of Marne, is the headquarters of the *Vins de Champagne*, and is situated in the midst of a rich vine-growing district, on the left bank of the Marne, 19 miles WNW. of Châlons. It is handsomely built, clean, and well paved. Its environs consist, for the most part, of elegant villas, with vaults attached, belonging to the Champagne wine-merchants. Epernay manufactures large quantities of earthenware from a clay obtained in the neighbourhood, and called *Terre de Champagne*; also hosiery, refined sugar, and leather. It has a brisk trade in bottles, corks, wire, &c., as well as wine. Pop. 22,000.

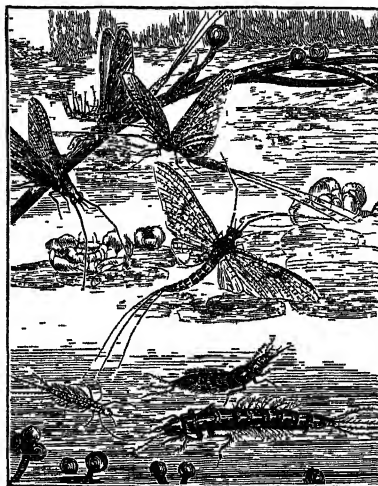

Ephah, a measure of capacity in use among the Hebrews, equivalent to about 8g, or, according to others, 6'468, imperial gallons.

Ephemera ('day-fly' or 'May-fly'), a genus of well-known insects which appear in vast numbers on summer evenings from rivers, canals, and ponds, and after a short merry life disappear as suddenly as they came. The genus *Ephemera* is type of the family Ephemeridæ or May-flies in the wide sense. The family is usually ranked among the amphibious Neuroptera, not far from Dragon-flies and Perlidæ.

A thin delicate body, with filmy wings, of which the anterior are much the larger and sometimes the only pair; rudimentary mouth-parts in the adults, which fast throughout their short aerial life; a long-lived voracious larval existence in the water, with so-called tracheal gills for aquatic respiration, are striking features of the Ephemerids. The antennæ are short and awl-shaped; the eyes of the males are very large; the head-shield is enlarged, covering the rudimentary mouth-parts; the middle ring of the thorax is exaggerated; the legs are delicate; the thin abdomen ends in two or three long filaments.

The life-history of these delicate ephemeral insects is very interesting. The eggs are laid in the water and give rise to aquatic larvæ, which live sometimes two or three years, moulting many times. They prefer running water, hide under stones or make burrows in the mud, have well-developed

mouth-parts, and feed hungrily enough on other insects. The tracheæ or air-tubes, as the figure shows, are expanded in plate-like or tuft-like paired structures down the sides of the posterior body. A pupa stage eventually follows, during which the larva acquires wings and other adult structures, but the insect which emerges and leaves the water is, curiously enough, not yet ready for its short adult life. Though it has wings, it is still encumbered by a delicate robe. This sub-imago, as it is often called, finds some resting-place on grass stem or tree trunk, gets rid of its last encumbrance, and begins its life of a day. The cast-off ghost-like exuviae are found in great

Metamorphoses of the May-fly.

numbers. In the summer evening the males and females enjoy a brief merry love-dance. The females are fertilised, the eggs are dropped into the water, and then sometimes in a single day the bright crowd is gone. It is literally true that at the moment of their climax they die.

The most familiar species is *Ephemera vulgata*, the common May-fly, the green drake (sub-imago) and gray drake of anglers. *Palingenia*, *Heptagenia* or *Baetis*, *Cloe*, *Caenis*, are almost common genera. The adult larvæ are used for bait; the corpses of the adults are sometimes abundant enough to serve as manure. The Ephemerids date back to the Devonian epoch. See ANGLING.

Ephemera (from Gr. *epi* and *hēmera*, 'on a day'), or FEBRIS DIARIA in Latin, a fever which lasts only a single day, or part of a day, and is generally dependent on some slight local irritation. It hardly requires any other treatment than the removal of the cause, if known.

Ephemeris. See ALMANAC, and DIARY.

Ephesians, EPISTLE TO, one of the letters written by St Paul during his imprisonment, probably at Rome. It is very doubtful if the epistle was written specifically to Ephesus. The earliest MSS. omit the words 'in Ephesus' in the opening verse, and it is difficult to suppose that the apostle would have written to a church where he had worked for three years, and must have made many friends, without sending personal messages and salutations. Many modern scholars regard the epistle as a circular letter addressed to a group of churches in the province of Asia. It forms a companion epistle to Colossians, with which it has many points of similarity. Both these epistles are characterised by a very exalted conception of the

Person of Christ, and in Ephesians the doctrine of the church is more highly developed than in any other epistle. The question of the Pauline authorship of Ephesians has been raised anew by Dr Moffatt in his *Introduction to the New Testament*. Dr Moffatt thinks that the style and linguistic characteristics of the epistle are un-Pauline, and that the theological outlook is in advance of that which we find in the genuine epistles. His arguments, however, are not conclusive, and the general tendency among modern scholars is to maintain the Pauline authorship of the epistle.

Ephesus, one of the twelve Ionic cities of Asia Minor, was situated in Lydia, near the mouth of the river Cayster, in the midst of an alluvial plain. It was long before Ephesus acquired any political importance, in spite of being a sacred city from an early period. Subdued first by the Lydian, and next by the Persian kings, it was included, after the death of Alexander the Great, in the territories of Lysimachus (281 B.C.), by whom it was greatly strengthened. Ultimately it came into the possession of the Romans; and in the time of Augustus, when Strabo wrote, it was 'the greatest place of trade of all the cities of Asia west of the Taurus.' This was also its condition when visited by St Paul, who resided here three years; but the destruction of its great temple by the Goths, in 262 A.D., gave it a blow from which it never recovered. In 431 it was the scene of the third general council of the Christian Church. Its general history, while a city of the Byzantine empire, was unimportant, and before the days of Tamerlane it had almost completely perished.—The ruins of Ephesus comprise a stadium 687 feet long, fragments of a great theatre (alluded to in the account of St Paul's preaching in the city), of an odeum or music-hall, and of various walls and towers, belonging to the Greek, Roman, and Byzantine eras. About a mile north-east of the ancient city was the site of the famous Temple of Diana. This marvellous building, one of the seven wonders of the world, was originally built by Chersiphron; but on the night (as is said) when Alexander the Great was born (356 B.C.), it was fired by Herostratus, an Ephesian, thereby to immortalise his name. It was afterwards rebuilt by the inhabitants in a style of greater splendour than before. It was the largest Greek temple ever constructed. Its length, according to Pliny, was 425 feet, its width 220; and the number of its columns 127, each 60 feet high. Wood's excavations (1869-74), carried much further and completed by Hogarth (1904-5), proved that there were two older temples under it (one of 600 B.C. and one of the time of Cræsus, apparently finer than its successor); and masses of votive tablets, statuettes of the goddess, and Egyptian scarabs were found. In the third temple were numberless statues and pictures by the best masters of Greece. The altar of the goddess was principally adorned with the works of Praxiteles. Plundered of its treasures by Nero, and burned (as has been mentioned) by the Goths, it was most likely finally destroyed by the iconoclasts, in the reign of Theodosius I., who issued his celebrated edict against the ceremonies of the pagan religion 381 A.D. The site is now occupied by some wretched villages, the principal of which is Ayasuluk.

See Falkner, *Ephesus and the Temple of Diana* (1862); J. T. Wood, *Discoveries at Ephesus* (1877); Fergusson, *The Temple of Diana at Ephesus* (1883); *Forschungen in Ephesus* (i. 1907); Hogarth, *Excavations at Ephesus* (1908); and the articles ARTEMIS and SEVEN SLEEPERS.

Ephod, a principal part of the official dress of the Jewish high-priest, was a vest of rich colour and materials, covering the breast and waist, with shoulder-straps; on each shoulder was placed an

onyx stone, with the names of the twelve tribes engraved, six on each, and a pouch for the Uim and Thummin. Ephods made of common byssus were worn by other priests.

Ephori (Gr., 'overseers'), an order of magistrates in ancient times which appears to have originated at Sparta, and to have been peculiar to the Doric governments. Herodotus attributes their creation to Lycurgus, and Aristotle to Theopompus (770-720 B.C.). Their duty was to superintend the internal administration of the state, especially affairs of justice, and to oversee some part of the education of youth. They were five in number, were elected by and from the people—on which Aristotle observes that through them the *dēmos* enjoyed a participation in the highest magistracy of the state—and held their office only for one year. Their influence gradually increased, for their powers were so ill defined that it was difficult to say what was *not* under their cognisance and authority. Ultimately the kings themselves became subject to the supervision of the ephori; thus, Cleomenes was brought before them for bribery, Agesilaus was fined, and Pausanias imprisoned. They also transacted the negotiations with foreign powers, subscribed treaties, raised troops, entrusted the army to the king or some other general, and, in fact, acted as the executive of the state. Their authority was at last destroyed by Agis and Cleomenes, who put the whole college to death, and restored the old Spartan constitution (226 B.C.). See Dum, *Entwicklung des Spartanischen Ephorats* (1878).

Ephraem Syrus, 'the prophet of the Syrians,' a celebrated teacher, orator, and hymn-writer of the Syrian Church, was born at Nisibis about 306. After Nisibis was taken by the Persians in 363 he removed to a cave near Edessa, which was already a chief seat of Syrian learning. He there devoted himself to prayer and fasting, and the study of the Scriptures. He died at Edessa about 378. His day is in the Roman Church the 1st of February, and among the Greeks and Maronites the 28th of January. Ephraem's strict orthodoxy, his asceticism, and his great learning were the admiration of his contemporaries; and the works he has left behind him, written in a fervid and popular style, sustain his reputation as an orator and poet. He was a most fertile writer. Part of his works have come down to us in their original Syriac, part in Greek, Latin, and Armenian translations. Of the Syriac writings the chief are his commentaries (based on the Peshito), extending to nearly the whole of the Old Testament, and they include also numerous discourses and elegies, mostly written in lines of seven syllables, grouped in strophes of from four to twelve lines each. Ephraem counteracted the influence of the Gnostic hymns of Bardesanes and Harmonius by writing better hymns of a strictly orthodox tendency. The Greek writings which bear his name are mainly sermons and short religious treatises. An edition containing 156 of these was published by Edward Thwaites at Oxford in 1709. There are editions by Assemani, in 6 vols. folio (3 vols. Greek texts and 3 vols. Syriac texts, with Latin translations, Rome, 1732-46), and Mercati (Syriac, Greek, and Latin, Rome, 1915, *et seq.*). The Syriac text of his select works was edited by Overbeck (Oxford, 1865). A tasteful English translation of a number of pieces was published by Henry Burgess in 1853. Ephraem's Commentaries on the Epistles of St Paul are extant in Armenian (ed. by Aucher, Venice, 1836). See treatises on Ephraem and his works by Lengerke (1831), Alsleben (1853), Gerson (1868), and Zingerle (1876).

Epiblast. See ECTODERM, EMBRYOLOGY.

Epicharmus, a famous Greek poet, was born in the island of Cos in the 6th century B.C. He spent the latter part of his life at the court of Hiero of Syracuse, and died at the age of ninety. Epicharmus is called by Theocritus the father of comedy, and Plato assigns to him a place among comic writers as high as that of Homer among epic poets. None of Epicharmus's works survive entire; but we possess several fragments and the titles of thirty-five. They embraced a wide variety of topics, mythological, social, and political. From one of them Plautus borrowed the plot of his *Menæchmi*. See Lorenz, *Leben u. Schriften des Epicharmus* (1864).

Epic Poetry (Gr. *epos*, 'a word,' 'a discourse'), the longest and most elaborate form of narrative poetry, wherein are celebrated continuously and in the grand style the momentous enterprises and great achievements of one or more heroic personages of history or tradition. A distinction is to be drawn between 'epics of growth' and 'epics of art.' Epics of growth consist of collections of ballads or poems composed by different authors at different times, and dealing with a connected series of events; examples are the *Kalevala*, the *Rāmāyana* and *Mahābhārata*, *Beowulf*, *Chanson de Roland*, and the *Nibelung* story (Icelandic version). In this sense the epic is one of the earliest poetic forms in which the human imagination has found expression, and is important not merely from a literary standpoint, but also from the point of view of the light so thrown on questions of sociology, ethnology, and archaeology. As distinct from epics of growth, epics of art are epics in which events are grouped round some great structural thought by a single poet consciously adopting the long-established form and accepted model of the epic of growth; examples are the *Argonautica* of Apollonius and of Flaccus, the *Aeneid*, the *Thebaid* of Statius, the *Lusiads*, *Paradise Lost*, and *Jerusalem Delivered*. Such epics as the *Iliad* and the *Shah Nameh* really belong to both classes at once, the raw material of the epic of growth being transformed in its passage through the mind of the master of the epic of art. From romantic poetry the epic form is mainly distinguished by a greater solidarity in its subject-matter. For subject the *Iliad* and *Odyssey*, Virgil's *Aeneid*, the *Poema del Cid*, Ariosto's *Orlando Furioso*, and Tasso's *Jerusalem Delivered*, and other epics turned to the achievements of the gods and heroes of old, or to the deeds of the little less mythic knights of mediæval chivalry; on a religious theme Milton, in his *Paradise Lost*, produced one of the world's greatest epics, and Klopstock wrote his *Messiah*; Lucan in his *Pharsalia*, Silius in his *Punica*, Camoens in his *Lusiads*, Ercilla in his *Araucana*, Voltaire in his *Henriade*, De Menezes in his *Henriqueida*, and others, went to the field of documented history, but all with ill-success, save Camoens, the field of authentic history being, from the nature of the case, much less rich in true epic inspiration than the field of fabled and storied antiquity.

Owing to the somewhat elusive nature of the conception of epic poetry, much diversity of opinion has always existed as to precisely what works are to be ranked as epics. Ossian's *Fingal*, however, would seem too empty of narrative interest for inclusion; Dante's *Divina Commedia*, if not something *sui generis*, is an allegory; Barbour's *Bruce* and Blind Harry's *Wallace*, though heroic, are hardly epic; Spenser's *Faerie Queene* is essentially allegorical; Southey's *Roderick* and Morris's *Life and Death of Jason* are in the last resort romantic; while Tennyson's *Idylls of the King* lacks both the arrangement and interrelation of an epic. Such poems as Scott's *Marmion* have been classed by some as genuine miniature epics. To quite another

class—the mock-epic—belong such poems as Pope's *Rape of the Lock*, Butler's *Hudibras*, and the like. It may be that with the advance of civilisation the epic manner has become in very large measure outworn, but certain it is that since the time of Milton no great epic has appeared, as witness in England the failure of Glover's *Leonidas*, and the small promise of success held out by Keats's unfinished *Hyperion*.

For various epics see separate articles, or articles on the authors of these epics; see also W. P. Ker, *Epic and Romance* (1897, new ed. 1922); J. Clark, *A History of Epic Poetry* (1900); G. Murray, *The Rise of the Greek Epic* (3d ed. 1924); H. M. Chadwick, *The Heroic Age* (1912); W. M. Dixon, *English Epic and Heroic Poetry* (1912); L. Abercrombie, *The Epic* (1917).

Epictetus, a celebrated disciple of the Stoa, was born at Hierapolis, in Phrygia, about 50 A.D. He was at first the slave of Epaphroditus, a freed-man of Nero, at Rome, and endured his severe treatment with characteristic stoic equanimity. After being manumitted he devoted himself to philosophy, and was banished by Domitian, along with several other philosophers, from Rome. He settled at Nikopolis, in Epirus. He left no works behind him, but his pupil Arrian, the historian of Alexander the Great, collected his maxims with affectionate care, in the work entitled *Enchiridion* ('Handbook') and in eight books of Commentaries, four of which are lost. These reveal the simple and noble earnestness of the philosopher's character, as well as that real heartfelt love of good and hatred of evil which is often assumed to be an exclusively Christian feeling. Epictetus believes in our 'resemblance' to God, in our 'relationship' to him, and in our 'union' with him through the coincidence of the 'will' and the 'soul'; he recognises the contest between good and evil, the life-struggle in the heart, the divine life against which the law in the members wars; and he affirms the necessity of 'invoking God's assistance in the strife,' that the inner life may become pure as God is pure. His ethics teach self-renunciation, endurance, and the duty of confining the ambition within the limits of the attainable. There are editions by Schweighauser (1799-1800), and Schenkl (1894-98). See STOICS.

Epicurus, an illustrious Greek philosopher, was born 341 B.C., in the island of Samos, where his father, Neocles, was a schoolmaster. At the age of eighteen he repaired to Athens, but his stay was short, and he returned to Asia. He had attached himself to the study of philosophy, especially that of Democritus; his own scheme of physics is evidently based on the atomic system of Democritus. At Mitylene he first opened a school of philosophy; and there and at Lampsacus and elsewhere he taught for some years. In 307 B.C. he returned to Athens, and established a school of philosophy in a garden which he purchased and laid out for the purpose. From this circumstance his followers were called the 'philosophers of the garden.' Although Epicurus laid down the doctrine that pleasure is the chief good, the life that he and his friends led was one of the greatest temperance and simplicity. They were content, we are told, with a small cup of light wine, and all the rest of their drink was water; and an inscription over the gate promised to those who might wish to enter no better fare than barley-cakes and water. The calumnies which the Stoics circulated concerning him are undeserving of notice, and were at no time generally believed. Epicurus's success as a teacher was signal; great numbers flocked to his school from all parts of Greece and from Asia Minor, most of whom became warmly attached to their master, as well as to his doctrines, for Epicurus seems to have been characterised not

less by amiability and benevolence than by force of intellect. He died 270 B.C., in the seventy-second year of his age.

Epicurus was a most voluminous writer. According to Diogenes Laertius, he left 300 volumes on Natural Philosophy, Atoms and the Vacuum, Love, the Chief Good, Justice, and many other subjects. These works are lost: the only writings of Epicurus that have come down to us are three letters, a few fragments from the *Volumina Herculanensia*, and a number of detached sentences or sayings, preserved by Diogenes Laertius. The principal sources of our knowledge of the doctrines of Epicurus are Cicero, Plutarch, and, above all, Lucretius, whose great poem, *De Rerum Natura*, contains substantially the Epicurean philosophy.

Although the majority of Epicurus's writings referred to natural philosophy, he seems to have studied nature with a moral rather than a scientific design. According to him, the great evil that afflicted men—the incubus on human happiness—was fear; fear of the gods and fear of death. To get rid of these two fears was the ultimate aim of all his speculations on nature.

He regarded the universe (*to pan*) as corporeal, and as infinite in extent and eternal in duration. He recognised two kinds of existence—that of bodies, and that of *vacuum*, 'the void'—i.e. space, or the intangible nature. Of his bodies, some are compounds, and some atoms or indivisible elements, out of which the compounds are formed. The world, as we now see it, is produced by the collision and whirling together of these atoms. He also held the doctrine of perception by *images* (Gr. *eidōla*), which are incessantly streaming off from the surface of all bodies, and which are necessary to bring us into *rapport* with the world without. In psychology he was a materialist, holding that the soul is a bodily substance, composed of subtle particles disseminated through the whole frame.

In seeking to understand the phenomena of the heavens he has no scientific end in view; his sole object is to enable the mind to account for them to itself, without the necessity of imagining any supernatural agency at work. He did not deny that there are gods; but he strenuously maintained that as 'happy and imperishable beings' they could have nothing to do with the affairs of the universe or of men. 'Beware,' he says, 'of attributing the revolutions of the heaven, and eclipses, and the rising and setting of stars, either to the original contrivance or continued regulation of such a being. For business, and cares, and anger, and benevolence are not accordant with happiness, but arise from weakness, and fear, and dependence on others.'

Having proved in his psychology that the dissolution of the body involves that of the soul, Epicurus argues that the most terrible of all evils, death, is nothing to us, 'since when we are, death is not; and when death is, we are not.' It is nothing, then, to the dead or the living; for to the latter it is not near, and the former are no longer in existence.'

He held that pleasure was the chief good, and it is from a misapprehension of the meaning of this word as used by him that the term Epicurean came to signify one who indulged his sensual appetites without stint or measure. At the same time, it is easy to see that the use of the word 'pleasure' was calculated to produce the mischievous results with which the later Epicureanism was charged. (For the Cyrenaic hedonism, see ARISTIPPUS.) According to Epicurus, the sources and tests of all ethical truth are the feelings, and these are two, pleasure and pain. We delight in the one, and avoid the other instinctively. 'When we say that pleasure is the end of life, we do not mean the pleasures of the debauchee or the sensualist, as some from ignorance or from malignity represent, but freedom

of the body from pain, and of the soul from anxiety. For it is not continuous drinkings and revellings, nor the society of women, nor rare viands, and other luxuries of the table, that constitute a pleasant life, but sober contemplation that searches out the grounds of choice and avoidance, and banishes those chimeras that harass the mind.' Epicurus rests justice on the same prudential basis as temperance. Denying any abstract and eternal right and wrong, he affirms that injustice is an evil, because it exposes the individual to disquietude from other men; justice is a virtue, because it secures him from this disquietude. The duties of friendship and goodfellowship are inculcated on the same grounds of security to the individual.

Among the Romans the system of Epicurus was adopted by many distinguished men. Horace, Atticus, and Pliny the Younger were Epicureans; Seneca, nominally a Stoic, drew much from Epicurus; and the great poem of Lucretius must have recommended the system to many. In modern times Epicureanism was resuscitated in France by Père Gassendi, who wrote Epicurus's life and a defence of his character in 1647; and many eminent Frenchmen have professed his principles.

See ATOM, ETHICS, DEMOCRITUS, LUCRETIUS; Zeller's *Philosophy of the Stoics, Epicureans, and Sceptics* (trans. by Reischel; new ed. 1880); W. Wallace, *Epicureanism* (1880); R. D. Hicks, *Stoic and Epicurean* (1910); and monographs by Gیزیcki (Halle, 1879), Kreibitz (Vienna, 1885), Cassel (Berlin, 1892), Bignone (Bari, 1920).

Epicycle. See PTOLEMAIC SYSTEM.

Epicycloid is the name of a peculiar curve. When a circle moves upon a straight line, any point in its circumference describes a Cycloid (q.v.); but if the circle moves on the convex circumference of another circle, every point in the plane of the first circle describes an epicycloid; and if on the concave circumference, a hypocyloidal. The circle that moves is the generating circle; the other, the base. The describing point is not necessarily in the circumference of the generating circle, but may be anywhere in a radius or its prolongation. It has many remarkable properties, and is even useful in the practical arts. The teeth of wheels in machinery must have an epicycloidal form, in order to secure uniformity of movement.

Epidaurus, a town of ancient Greece, on the eastern shore of the Peloponnesus, in the district of Argolis. During the most prosperous period of Grecian history Epidaurus was an independent state. The form of government was originally monarchical, but, after many vicissitudes, it eventually became and remained oligarchical. At an early period Epidaurus became one of the chief commercial cities of the Peloponnesus. It was chiefly famous for its temple of Æsculapius, to which patients resorted from all parts of the Hellenic world, seeking a cure for their diseases. The site of this temple, about 5 miles west of the town, is still called Hieron, 'the sanctuary.' Epidaurus had also numerous temples and a magnificent theatre, at present in a more perfect state of preservation than any other in the Peloponnesus, with sufficient accommodation for 12,000 spectators. At the modern *Epidavro*, a small village, in January 1822 a congress from all parts of Greece assembled, and promulgated the constitution known as the constitution of Epidaurus.

Epidemic (Gr. *epi*, 'upon,' and *dēmos*, 'people'), a disease which attacks unusual numbers of people simultaneously or in succession, and which, in addition, may travel from place to place. A disease which habitually affects numbers of persons in one locality is called Endemic (q.v.). By primitive men, epidemics above all other forms of sickness tend to be regarded as due to super-

natural agency; and until the middle of the 19th century, when the doctrine of contagion as caused by living germs came to be generally accepted, epidemics were held to be the result of some peculiar change in the constitution of the atmosphere. This idea appears clearly in the works of Sydenham during the 17th century.

Most epidemics are now traceable to the development of disease-producing microbes. Occasionally an epidemic is the result of some impurity in the food supply of a district, e.g. symptoms set up by lead or arsenic in beverages commonly drunk, as in the arsenic poisoning epidemic caused by impure beer in 1900, and the ancient attacks of ergotism in France, caused by the presence of a fungus in diseased rye-bread. See ERGOT.

The diseases which produce the most common epidemics, and which affect especially young persons, for example, scarlet fever, measles, enteric fever, whooping-cough, diphtheria, are always present among the community. At definite seasons, as Buchan and Mitchell have shown, they become more virulent and affect a greater number of people, and they then attract special attention as epidemics. For example, in London on an average of the years from 1861 to 1900 the deaths from scarlet fever in November were about three times as numerous as those from the same disease in March, there being a continual but varying number through the other months of the year. There is thus a tendency to epidemics of this disease during the late autumn; and the other infectious diseases have a similar seasonal variation, with regularly recurring epidemics in some definite month or months of the year. Thus enteric fever epidemics recur about August, and reach their height in October and November; diphtheria is commonest from September to December; whooping-cough from January to April; while measles has a double outbreak each year in June and in December; and smallpox tends to become serious especially in January and May. Infantile diarrhoea appears at the hottest period of the year, and is worst when a specially hot summer supervenes. In addition to this annual variation most of these diseases have a tendency to recur with special severity every four or five years, and when the history of the centuries is examined it is found that some of the most fatal diseases have tended to sweep widely over the world in recurring cycles separated by many generations. This feature is often to be explained on the basis of an inherited immunity, which the community loses when the disease has been quite absent for a long period; for example, in 1875 measles being introduced into the Fiji Islands for the first time, more than a quarter of the whole population died from the effects. For details regarding infectious diseases, see CHOLERA, PLAGUE, SMALLPOX, &c., and for their prevention see INFECTION.

History of Epidemics.—In the middle ages, as a result probably of the insanitary conditions found in crowded fortified cities, as well as owing to personal uncleanness, epidemics proved a terrible scourge. The disease known as Plague, Pestilence, or 'Black Death,' was especially terrifying. The plague of Athens, described by Thucydides, is now generally identified as having been either typhus or cerebro-spinal fever, while the no less celebrated epidemic in the time of Marcus Aurelius was very probably enteric fever. The first account of bubonic plague in Europe as we now know it, a very fatal infectious disease with glandular swellings or buboes, dates from the 6th century A.D.—the plague of Justinian. The great epidemic or series of epidemics in the 14th century, known as the 'Black Death,' appears to have started in China, and after a few years reached Europe, which it

ravaged in a succession of outbreaks throughout that century. In the whole of Europe, Hecker calculates that one-fourth of the population, or 25,000,000 people, died. In the 15th and 16th centuries there were numerous epidemics of plague, but during the 17th century it had largely died out, though Defoe makes it memorable by his *Story of the Great Plague* in London in 1664–65. Since then various outbreaks of markedly slighter severity have occurred in Europe.

Another disease which broke out in epidemic form in England during the 15th and 16th centuries, and from which many people died, was the 'sweating sickness,' which has been identified with the 'Picardy Sweat,' an epidemic often affecting France in the 18th and early 19th centuries.

Still another disease of which epidemics can be traced back to the 9th century in France, and which is portrayed in numerous ancient pictures and MSS., is that known variously as *St Anthony's Fire*, *Ignis Sacer*, *Mal des Ardents*, or by its modern name of *Ergotism*. This has been a good deal confused with erysipelas, but is quite a different disease, due to eating bread made from rye in which the fungus *Claviceps purpurea* has developed. The disease was characterised by excessive pain and mortification of the limbs, which turned black as if they had been burned up with fire; often also there were spasms, and the malady came on suddenly in religious houses, towns, or whole districts, where bread had been made from the diseased grain. It occurred right up to the 17th century, when its nature became known, so that its prevention is now possible.

Typhus fever, which has received numerous names, such as pestilential, putrid, jail, and hospital fever, has long been known throughout Europe as productive of deadly but very limited epidemics. Old writers tell of its ravages in beleaguered towns, and of the 'black assizes,' where judges, jurymen, and public fell victims to an epidemic brought into court by prisoners from the jails. It has been confused with cerebro-spinal or 'spotted' fever, which resembles it in causing a stuporous condition and a purple eruption, as well as in affecting barracks, jails, and other crowded localities.

Cholera, which is constantly endemic in the deltas of India, frequently during the 19th century spread in epidemic form along the trade-routes by sea to Egypt, or by land through Persia, and produced outbreaks of the disease in Europe.

Mental diseases tend to occur in epidemic form, not only because profound disasters like war, famine, and plague leave the community mentally unbalanced, but also because even in ordinary times the type of insanity and nature of delusions conform to current habits and events. Thus in the mediæval state of society, when wide, lonely spaces existed between towns and habitations, and when human beings were subject constantly to the attack of wild animals, a common form of insanity was that of the *Werewolf* (q.v.), *loup garou*, or, as known to the Greek medical writers, *lycanthropy*. Men and women imagined themselves turned at times into wolves or other animals, roamed in the forests, and attacked those against whom they had a grudge. The idea was fostered by a wealth of folk-lore, tradition, and superstition, and the Bishops Olaus Magnus and Majolus in the 16th century state that in Prussia, Livonia, and Lithuania, the werewolves were far more destructive than the 'true and natural wolves.'

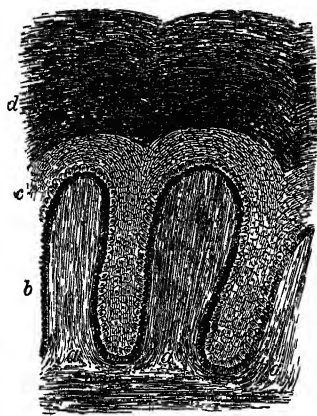

Another type of mental epidemic is found in the various outbreaks of dancing mania. After the outbreaks of plague in the 14th century, parties of people called Flagellants, who assumed responsibility for the sins of the community, went through

the countries of Europe dancing and scourging themselves in expiation. The dancers who betook themselves for cure to the shrines of St Vitus from 1374 onwards, the leaping ague which affected the people of Forfarshire in the 18th century, and limited outbreaks of religious dancing in the United States in the 19th century, are examples of similar mental affection involving many people.

See Hecker's *Epidemics of the Middle Ages* (Eng. trans. 1846); Hirsch's *Historical and Geographical Pathology* (Eng. trans. 1883-85); Creighton's *History of Epidemics in Britain* (1891-94); Sticker's *Abhandlungen* (1908-12); and *Handbuch der Geschichte der Medizin* (1903, ii. 736-901).

Epidermis (Gr. *epi*, 'upon,' and *derma*, 'the skin'), scarf-skin or cuticle, forming an external covering of a protective nature for the true skin or corium. Its under or attached surface is accurately moulded upon the true skin, and when the two are separated the cuticle presents impressions which exactly correspond to the elevations and depressions in the corium. The thickness of the epidermis varies from $\frac{1}{100}$ to $\frac{1}{50}$ of an inch, according to the amount of protection which the delicate and sensitive corium requires in different localities.

Thus, it is thickest and hardest in the palms of the hands and soles of the feet, but this is not altogether the result of an increased growth due to intermittent pressure, for the difference is well marked even in the foetus. The epidermis consists of many layers of stratified cells superimposed on each other; and since they cover a free surface exposed to the air, the cells are classed in the group of stratified epithelia. The cells vary in shape, those placed next the

Perpendicular Section of the Skin of the Leg of a Negro (magnified 250 diameters):

a, a, papillæ of the cutis; b, deepest intensely coloured layer of perpendicularly elongated cells of the mucous layer; c, upper stratum of the same layer, d, horny layer.

corium being elongated in form, while those most superficial are flat and scale-like. On this account it is usual to describe the epidermis as consisting of two strata—an outer or *superficial horny stratum*, and a deeper or *mucous stratum* (or *rete Malpighii*). The *horny stratum* consists of cells, many of which have lost their nuclei and assumed the form of hard flattened scales of polygonal outline. The deepest layer of this stratum consists of closely packed cells with indistinct outlines and a clear, almost homogeneous, appearance, which has given them the name of the *stratum lucidum*. The superficial cells of the horny layer are regularly cast off by desquamation, and replaced by those beneath them. In reptiles and amphibians this layer is periodically cast off in a more or less entire state, a new one being previously formed beneath it; and in man desquamation in large patches occurs after certain diseases, especially scarlet fever.

The *mucous stratum* lies next the corium. It consists of nucleated cells of various shapes. Those next the corium are elongated and placed perpen-

dicularly to its surface. Above these are cells more rounded or polyhedral in outline, and possessing many spines or pickle-like processes, by the points of which the cells adhere to each other, and thus leave fine lymph channels through which the nutrient plasma is transmitted to the cells. The colouring matter of the epidermis is found in the cells of the mucous stratum. A more or less dark pigment is often deposited in the face, neck, and hands of the fair races of men during exposure to the sun, forming isolated colour-spots called freckles; but in the dark races the pigment-granules are distributed throughout the cells of the mucous stratum, the deepest or perpendicular cells being the darkest. Instances of white negroes are on record, not as a consequence of change of climate, but as an abnormal condition of the epidermis. Fine nerve-fibrils penetrate between the cells of the mucous stratum, and undergo a certain amount of ramification, but do not form a network. In some reptiles, and in the Edentata among mammals, the epidermis forms large plates or scales, while epidermal appendages assume various forms—e.g. hair, nail, spines, bristles, feathers, claws, hoof, horns, &c.

In plants the epidermis is formed of flattened cells, usually only one layer deep, frequently bearing hairs and stomata. The exposed cell-walls upon the outer surface are frequently thickened as the cuticle. See LEAF.

Epidote. Under this name are included several minerals, which are of some importance as rock-formers. Only two need be mentioned here, *Zoisite* and *Pistazite*, or *Epidote proper*. Zoisite, or lime-epidote, is a silicate of alumina and lime, the alumina sometimes being replaced by ferric oxide to the extent of 2 or 3 per cent. It crystallises in rhombic prisms, which are often curved or sharply bent. Usually it occurs as large imbedded crystals or as foliated and columnar aggregates, chiefly in crystalline schists, especially such as are rich in amphiboles. It is generally light-coloured—white, yellowish, or brownish-gray. Its hardness = 6½. Pistazite, or epidote proper, is a silicate of alumina and lime in which the alumina is replaced by ferric oxide up to 17 per cent. or thereabout. Hence it is often spoken of as iron-epidote. It has a peculiar dark yellowish-green colour, known as pistachio-green. It crystallises in monoclinic prisms, and has a hardness similar to that of zoisite. The largest and best developed crystals are met with amongst the crystalline schists and gneisses, and not infrequently in metamorphosed limestones. In eruptive rocks it occurs only as a decomposition-product after pyroxenes, amphiboles, micas, and felspars.

Epigastrium (Gr. *epi*, 'over,' and *gaster*, 'the stomach'), the part of the Abdomen (q.v.) which chiefly corresponds to the situation of the stomach, extending from the sternum towards the navel or umbilicus. It is called in popular language the pit of the stomach.

Epigene (Gr. *epi*, 'upon,' *gennaō*, 'I produce'), a term applied to those geological agents of change which affect chiefly the superficial portions of the earth's crust, as the *atmosphere*, *water*, *plants*, and *animals*. See GEOLOGY.

Epigenesis, a technical name for the modern conception of the development of the organism by the growth and differentiation of a simple germ—i.e. by the division or segmentation of a fertilised egg-cell. This conception, now a commonplace, was first definitely enunciated by Harvey (1651), and was reasserted with cogent demonstration by Wolff in 1759, in opposition to the generally received theory that the germ contained a pre-

formed miniature model of the organism which only required to be unfolded. See EMBRYOLOGY.

Epiglottis, a cartilaginous valve which partly closes the aperture of the larynx. See LARYNX, and DIGESTION.

Epigoni. See ADRASTUS, THEBES.

Epigram, a word derived from the Greek, and literally signifying an 'inscription.' The epigrams of the Greeks were simply inscriptions on tombs, statues, and monuments, written in verse, and marked by great simplicity of style, extended to any short, terse thought in verse. The founder of the art was Simonides of Ceos, many of whose epigrams were inscribed on the tombs of the heroes who fell in the Persian war. It was among the Romans that the epigram first assumed a satirical character; the greatest Roman masters were Catullus and, in particular, Martial, whose obscenity unhappily was more easily imitated than his genius. In modern times an epigram is understood to be a very short poem, generally from two to eight lines, containing a witty or ingenious thought expressed in pointed phraseology, and in general reserving the essence of the wit to the close, as the serpent is fabled to keep its sting in its tail. It may be the medium for the expression of almost any feeling, provided only it is in form brief, pointed, and exquisite. Epigram, however, fits best the expression of satire—an admirable example is that of Rogers:

Ward has no heart, they say, but I deny it;
He has a heart, and gets his speeches by it.

The Latinists Scaliger, Buchanan, More, Stroza, and John Owen (1560-1622) wrote epigrams, and the form was later kept in artificial life by Vincent Bourne, Porson, Byron, and Walter Savage Landor. Sir William Watson has produced some excellent examples of the epigrammatist's craft. In earlier generations of English literature the epigram was a favourite form, almost every poet in the 16th and 17th centuries having written them. John Heywood 'invented and did' as many as six hundred; other past but forgotten masters are Thomas Freeman, Samuel Sheppard, Thomas Bastard, Thomas Bancroft, and Henry Parrot. A few examples by Herrick, Quarles, and Ben Jonson still survive, while many thousands that cost much labour in the making sleep in secure oblivion. The French excel all other nations in the epigram. Their earliest epigrammatist of any note was Clément Marot (1495-1544); their best are J. B. Rousseau, Lebrun, Voltaire, Marmontel, Piron, and Chénier. The epigrams of German writers are for the most part happily expressed moral proverbs (*Sinngedichte*), but the *Xenien* of Schiller and Goethe contain not a few sharp and biting verses of a satirical character. Logau's famous *Deutscher Sinngedichte Drey Tausend* appeared in 1654; later epigrammatists were Kleist, Opitz, Gleim, Hagedorn, Klopstock, A. W. Schlegel, Lessing, and Herder. A large collection of English epigrams was that of Veever (1599). Good epigrams have been written by Cowley, Waller, Dryden, Prior, Swift, Addison, and Young; but the greatest master of the epigrammatic spirit in our literature is Pope.

See Booth, *Epigrams, Ancient and Modern* (1863); Dodd, *Epigrammatists of Medieval and Modern Times* (2d ed. 1875); Adams, *Book of Epigrams* (1879); Aubrey Stewart, *English Epigrams and Epitaphs* (1897); R. M. Leonard, *Epigrams* (1915).

Epigraph (Gr. *epi*, 'upon,' and *graphō*, 'I write'), a terse inscription placed upon architectural or other monuments, for the purpose of denoting their use or appropriation, and very frequently worked in and forming part of their ornamental details. See INSCRIPTIONS.

Epilepsy (*epilepsia*, 'a seizure') is recognised by loss of consciousness and a convulsion. It is the underlying morbid condition, however, not the mere seizures, that constitutes the disease. It affects all races of man, and is not unknown among lower animals. Its striking phenomena have been described by the oldest medical writers. By the ancients it was regarded as due to demoniac possession, or to the anger of an offended deity. Their physicians called it the *morbus sacer*. Hippocrates alone, to his credit, maintained its origin was no more supernatural than any other disease. The common English name is the 'falling sickness.'

The word 'epilepsy' is now used largely as a symbol under which are grouped a great variety of conditions due fundamentally to faulty energy distribution. The nervous system consists of a large number of receiving organs by which impressions from the outside world are derived. These, through processes of cerebral association, are elaborated into the physical equivalents of psychic products of higher complexity which are eventually transformed into further physical complexes whose function is to set in action the lower motor centres, and produce the appropriate muscular response. As the in-coming stimuli are so many, the out-going activities are correspondingly diverse, but a healthy organism is able, by reason of its nervous mechanisms, so to distribute the energy received as to bring about a series of harmoniously adjusted activities. The failure to properly utilise and distribute its energy efficiently characterises the epilepsies. The epileptic discharge is thus essentially a manifestation of energy at greatly reduced adaptive efficiency, and indicates that the essential defect is destructive, and causes a blocking of paths of outlet structurally, or by inhibition, and thus accumulates the discharge within relatively narrow paths.

The genuine epileptic comes from a tainted stock. Epilepsy may not appear in the ancestors, but they and often the collaterals show evidences of various ill-defined nervous disorders. Epilepsy and feeble-mindedness show a similarity in their hereditary reactions, and appear to be due to a defect in the germ-plasma—i.e. they are both recessives. They are often found associated.

Seizures of an epileptic character may be associated with organic disease of the brain—e.g. injury, congenital defect, tumour, vascular lesions, syphilis, and arterio-sclerosis. The late Dr Hughlings Jackson described a type of fit in which the convulsive movements are first limited to one group of muscles, and involve progressively further muscle groups—e.g. they may begin in the hand, and spread to the arm, trunk, and leg. Consciousness is not usually lost unless the convulsion spreads to the opposite side. This type is termed 'Jacksonian epilepsy,' and occurs when the lesion presses on or involves the motor area of the brain. It may be cured by operation.

Essential epilepsy is usually divided into two main types: (1) The *severe form*, or epileptic fit proper (the *grand mal* of the French). The onset is sudden, but may be preceded by a warning, the *aura*. It is often ushered in by a cry. The loss of consciousness precedes or accompanies the cry, and the patient falls down in a state of tonic spasm. The face becomes livid and cyanosed, and respiration is in abeyance. This stage may last from a few seconds to a minute and a half. The first sign of yielding is the development of a fine rapid tremor, which soon gives place to sudden, quickly repeated, shock-like contractions of greater degree and severity, which occur at gradually lengthening intervals, and finally cease after two or three desultory jerks. The duration of the

clonic stage varies, but is longer than the tonic, and is followed by muscular relaxation and stupor, from which the patient passes into deep sleep, and finally recovers. On awakening he is quite unconscious of what has happened; he may have a severe headache, or be morose or irritable, and in some cases feels much freer mentally than before the onset. In rare cases, just before or more commonly after the convulsion, a condition of active excitement may occur—*epileptic mania*—during which he may be homicidal or suicidal. Fortunately the efforts are diffuse and not coherently directed; the attack is usually brief and calls for restraint, but ends in complete exhaustion. Although epileptic seizures usually occur separately, several may follow each other at such short intervals that the attacks merge into one another and overlap, and unconsciousness becomes continuous, a condition known as *status epilepticus*. This is very dangerous, and often fatal. The convulsion may be replaced by what is termed an *epileptic equivalent* or *psychic epilepsy*. In this state almost anything may be done, and the patient has no recollection of what has happened after it is over. In the early stage of a seizure there is a danger of the patient falling into the fire, or being drowned in a bath, and in the tonic phase suffocation may occur from the face being buried in the pillow. During the clonic stage tongue-biting is common.

(2) *Slight forms (petit mal)* may be merely a momentary confusion of thought or loss of consciousness. The patient may simply pause for an instant during conversation, look strange, and then go on with what he was saying. Or he may fall down and get up again immediately, or there may be a feeling of faintness, or a momentary twitching of one or more groups of muscles, with pallor of the face and unconsciousness. This form may be followed by a somnambulistic-like stage of *automatism*, during which some unusual or inappropriate act may be performed of which there is no recollection afterwards. Perhaps the commonest act is undressing. The medico-legal aspect of these cases is of importance, since a patient, in a condition of post-epileptic automatism, may commit serious and complicated crimes, of which he has afterwards no knowledge.

The major seizures may occur for many years without any special degree of dementia resulting, this being largely determined by the frequency of the attacks. The usual psychical state of the minor type is a mild degree of mental impairment, chiefly loss of memory for recent events. The combined type with both major and minor seizures shows the greatest frequency of fits, sometimes several hundred a month, and presents the most profound degrees of dementia, little influenced by treatment.

Essential, or idiopathic, epilepsy is now regarded as a life-reaction comparable to rage or anger in a bad-tempered individual, of excessive emotionalism in the supersensitive. The epileptic constitution, independent of the deteriorating influence of excessive attacks, which only brings it more markedly in view, was recognised about 1860. At birth the potential epileptic children have fits of meaningless crying. As they grow up their non-pliability to nursery ethics—obedience and deportment—becomes obvious. Extreme lability of mood is frequent. Consecutiveness of purpose in play and capacity to be amused is short. Tantrum episodes are common. Their maladaptive defects are shown with other children. They demand the play to be arranged to suit themselves; the game must be played a certain way, and continued or stopped as they direct. Their likes and dislikes are extreme. At school interest and attention continually vary. Extreme brilliance in some subjects and ignorance in others is the general rule.

Because of their extreme nervousness and inability to conform to school routine they become intolerant of school life and rebel at its demands. Thus in infancy and early childhood the adjustment to the social and physical environment is incomplete and unsatisfying; and, thrown back on itself, there is a reinflation of self-importance and sensitiveness. Childhood is thus a fruitful period for new stresses, and hence epileptic attacks occur in the predisposed. The next stressful period is puberty. They are unwilling to take on a proper attitude of apprenticeship. They have the innate instability of the constitutional inferior without his good-natured indifference; their feelings are easily hurt; they have ill-defined paranoid persecutions, which cause them to react frequently with violence, insolence, and hatred. The lack of good-fellowship renders them incapable of co-operative teamwork; the requirements of interdependence and subordination to the main purpose galls and irritates them beyond endurance. During adolescence they begin to present an odd mixture of primary defects of instincts. With no intimate friends, the potential epileptic holds himself aloof; he is a free-lance, able and usually anxious to work his will upon the world. Freed from the trammels of social concern and demand, the intellectual efforts of the potential epileptic work with less stress than the normal, but the social customs of the family, friends, and society fail to add their modifying influence as a directing force. In consequence new and unforeseen hindrances are added which reduce the mental and physical invulnerability to the minimum, and at such defective periods some physical stress, which at a more favourable time would be quite negligible, appears as the precipitator of the frank disorder.

Essential epilepsy is thus dependent upon a primary congenital defect or inheritable defective instincts of natural and healthful adaptations to reality, the epileptic make-up or constitution, and at successive periods in life, when emotional and physical stresses of an intensive character are encountered, the individual so constituted has epileptic reactions, such as fits, disturbances of temper, lethargies, and various psychic phenomena. The fit is essentially a regressive phenomenon, a flight from undue stress into unconsciousness, the deeper manifestations of which, the convulsive phenomena, are superadded.

The proper treatment of epilepsy is an intensive and persistent educational training, together with the correction of such mental and physical disorders as are remediable by more conscious methods, as occupation, educative play, and healthful interests and pursuits.

During a fit the patient should be laid on the floor. Anything likely to constrict the neck should be removed. Tongue-biting may be prevented by inserting a cork between the jaws. The post-paroxysmal sleep should be encouraged.

Medicinal treatment consists mostly of bromide. The addition of a little arsenic helps to prevent acne. For success it must be persevered in for long periods. In addition, restriction of salt, free purgation, and simple diet with diminution of meat, is helpful. Recently good results have been found in essential epilepsy from luminal. Treatment should be continued for two years after the last fit before recovery can be said to have taken place. The occupation should be one in which there is no risk of life when a fit occurs. Alcohol must be forbidden.

The social position of the epileptic is most unfortunate. Often so impaired mentally that his labour is at a discount, he loses his employment on the occasion of his first fit, even though the work may be suitable. Hence the urgent need for early

care and supervision in an epileptic colony where all such social handicaps are removed.

Epilobium (or WILLOWHERB, from its characteristic habit and silky-tufted seeds), a widely diffused herbaceous perennial genus of Onagraceæ, common in moist places. *E. angustifolium* is one of the most familiar denizens of the cottage garden, and is also common in shrubberies. In arctic regions its young shoots are sometimes eaten in case of need, and in Kamchatka a kind of beer is made from the sugary pith. This species, with several others, is common in North America, where it is sometimes called *fire-weed*, since it often covers the scenes of great forest fires, and sometimes *slink-weed*, from a belief that it causes cows to 'slink' or miscarry. About a score of other species are occasionally seen in gardens.

Epilogue (Gr. *epi*, 'upon' or 'after,' and *logos*, 'a speech') means, in oratory, the summing up or conclusion of a discourse; but in connection with the drama it denotes the short speech in prose or verse which was frequently, in former times, subjoined to plays, especially to comedies, as contrasted with the Prologue at the beginning. The epilogue was always merry and familiar in its tone, and was intended to establish a kindly understanding between the actor and the audience, as well as to conciliate the latter for the faults of the play, if there were any, and to send them away in good humour. One of the neatest and prettiest epilogues ever written, and one which completely realises what an epilogue should be, is that spoken by Rosalind at the conclusion of Shakespeare's *As You Like It*.

Epimenides, a Greek poet and priest, sometimes included among the 'seven sages,' was born in Crete in the 7th century B.C. According to one tradition, during a sleep of fifty-seven years he received the divine inspiration which determined his future career. (Goethe wrote a poem on the subject, *Des Epimenides Erwachen*.) He was reputed to have lived for 299 years. Epimenides went to Athens about 596 B.C., where, by the performance of various mystical rites and sacrifices, he stayed a plague with which the inhabitants were afflicted, and co-operated with Solon in reforming the Athenian constitution. He was the 'prophet' quoted by St Paul in Tit. i. 12. That he wrote the epic poems attributed to him, the longest of which was on the Arponautic expedition, is improbable. Doubt has been cast on his historical existence.

Epinal, capital of the French dep. of Vosges, delightfully situated at the western base of the Vosges Mountains, on the Moselle, 46 miles SSE. of Nancy. It is a clean, well-built town, surmounted by the ruins of an old castle. Among its buildings are the church of St Maurice (c. 960), the museum, and a library rich in manuscripts. Epinal manufactures cotton, paper, &c. A fortified town, it was occupied by the Germans in 1870, but in the Great War escaped determined attempts to reach it. Pop. 28,000, largely increased after 1870 by the influx of Alsatians.

Épinay, LOUISE TARDIEU D'ESCLAVELLES, MADAME D' (1726-83), a French writer, born at Valenciennes, at nineteen married her cousin. The union proved an unhappy one, and she struck up liaisons with men of genius—first with Rousseau, for whom in 1756 she built a cottage (the now famous Hermitage) near the valley of Montmorency, and then with Grimm. She spent her last years in comparative solitude. Her *Conversations d'Emilie* (1774), a work on education, was crowned by the Academy. See ROUSSEAU; Perey's *Jeunesse et dernières Années de Madame d'Épinay* (1882); and her *Memoir and Correspondence* (trans. 3 vols. 1899).

Epiornis. See *ÆPYORNIS*.

Epiphanes. See *ANTIOCHUS*.

Epiphanius, a Christian bishop and writer of the 4th century, was born of Jewish parents in Palestine. He was educated among the Egyptian monks, who imbued his mind at once with a fervent piety and an intolerant bigotry that together led him in after-life into most unchristian excesses. He rose gradually to the rank of Bishop of Constantia (formerly Salamis) in Cyprus, and continued in that office from 367 till his death in 403. His polemical zeal was conspicuously manifested against Origen. He had proclaimed him a heretic in his writings, and in 394 he went to Palestine, the stronghold of Origen's adherents, and called upon John, Bishop of Jerusalem, to condemn him. Both in this instance and in his conduct to Chrysostom afterwards, he displayed a tyrannical and intolerant passion. Among his writings, collected by Petavius (2 vols. Paris, 1622), the most important is his *Panarion*, or catalogue of all heresies (80 in number), a work which strikingly shows his unfitness for the task of a historian. See a monograph by Lipsius (Vienna, 1865).

Epiphany (Gr. *Epiphaneia*, 'manifestation') denoted, among the heathen Greeks, the appearance of a god to a worshipper. The word was subsequently used to designate the manifestation or appearance of Christ upon earth to the Gentiles, with especial reference (in the Western Church) to his adoration by the Magi (q.v.). This occasion is commemorated on 6th January, the 12th day after Christmas, and hence the Epiphany is also called Twelfth Day (q.v.). Until the latter end of the 4th century, the 6th January was a festival in honour of Christ's nativity and baptism. See *BEFANA*.

Epiphytes (Gr. *epi*, 'upon,' *phyton*, 'a plant'), often and popularly, but less correctly, called Air-plants, are plants which are not rooted in the ground, but are attached to trees, &c. Mosses and lichens themselves, growing upon trees, may be called epiphytes, but the term is generally used of phanerogamous plants. It is chiefly in warm and moist climates that phanerogamous epiphytes are found, and in those which are also moist, although many exhibit considerable endurance of drought. Most of them prefer shady situations. Within the tropics, they often form an interesting and remarkable feature of the vegetation. Some of the Bromeliaceæ (as *Tillandsia*), Cactaceæ, Araceæ, Gesneriaceæ, and other orders are epiphytes; most frequently, however, the Orchidaceæ. See *ORCHIDS*, *TILLANDSIA*, &c.; and Kerner's *Pflanzenleben*.

Epirus ('mainland'), the ancient name of a part of Greece, extending between Illyria and the Ambracian Gulf, and from the Ionian Sea to the chain of Pindus. It was a wild and mountainous region, heavily wooded, and producing but little corn, though celebrated for its cattle and horses, and for its breed of Molossian dogs. The principal rivers were the Aous, Arachthos, Thyamis, and Acheron (q.v.); the chief towns, Dodona (q.v.) and Ambracia (q.v.). Anciently, as to-day, the inhabitants were only half Hellenic, the Greek colonies being confined to the coast and southern portion. Of the Molossian kings of Epirus, the most famous is Pyrrhus (q.v.), who long waged successful war against the Romans. On the conquest of Macedonia by the Romans (168 B.C.), the most revengeful measures were put in force against the Epirotes, who had assisted Perseus, the Macedonian king. Æmilius Paulus, the Roman general, plundered and razed to the ground seventy towns of Epirus, and sold into slavery 150,000 of the inhabitants. From this period, Epirus shared the vicissitudes of the Roman and Byzantine empires,

until 1204, when one of the Comneni made himself independent. Petty princes ruled the country until the 15th century, when it was conquered by the Turks (see SCANDERBEG). Peopled largely since the 14th century by Albanians (see ALBANIA), the strip of territory east of the river Arta was, under pressure from the great powers, ceded by Turkey to Greece in 1881, while after the wars of 1912-13 the western portion fell to Greece and Albania.

Episcopacy. See BISHOP.

Episcopius, SIMON (properly *Biscop*), the leader of the Arminian party after the death of its founder, was born at Amsterdam in 1583, and studied (from 1600) at Leyden. Arminius and Gomarus were his teachers in theology, and on the death of the former in 1609 Episcopius was obliged, on account of his known attachment to Arminius' views, to leave Leyden for Franeker. In 1610 he became pastor at Bleysswich, a village near Rotterdam, and in the following year he was one of five 'Remonstrants' appointed by the government to meet five 'Contra-Remonstrants' at a conference at the Hague. When Gomarus resigned his chair at Leyden, Episcopius was appointed his successor (1612). Called with twelve other Arminian theologians to the bar of the Synod of Dort (1618), Episcopius (with the rest) was condemned and banished from the country. He removed to the Spanish Netherlands, where he wrote his famous *Arminian Confessio* (published in 1622). On the renewal of the war between Spain and Holland, he found refuge in France, where he lived mostly at Paris and Rouen, and published a series of able controversial treatises. Permitted in 1626 to return to his native country, he was for several years a preacher at Rotterdam, where he wrote his *Apologu pro Confessione* in 1629. From 1634 he was professor at the Arminian College at Amsterdam, and here he produced his *Institutiones theologicæ* and *Responsio ad Questiones Theologicæ*, two works which are mutually complementary, and which, though the former was left incomplete at his death in 1643, present an ample apology not only of Arminian theology, but of the Christian revelation itself. Episcopius everywhere lays the utmost stress on the personal responsibility of man in relation to divine grace, denies the doctrine of original sin, and treats Christian faith not as a doctrinal theory, but as the potentiality of right moral conduct. Yet it cannot be denied that, in his view of the Trinity, the Son and the Holy Spirit are partakers of divine power and glory *non collateraliū sed subordinatē*, and that he held it enough to believe that the Holy Spirit proceeds only from the Father, and is the spirit of the Son. This rationalistic development of Arminian doctrine by Episcopius went far beyond the famous Five Articles of 1610, but in the next generation was generally adopted by the Arminian party. His works were collected in 2 vols. (Amst. 1650-65). The best Life is Philip Limborch's *Historia vitæ Simonis Episcopii* (Amst. 1701). See ARMINIUS, CALVINISM; and Sepp, *Het godgeleerd onderwijs in Nederland* (1873).

Epistles. See BIBLE.

Epistolæ Obscurorum Virorum ('Letters of Obscure Men') is the title of a collection of satirical letters which appeared, in dog-Latin, at the commencement of the 16th century, and professed to be the composition of certain ecclesiastics and professors in Cologne and other places in Rhenish Germany. They were directed against the scholastics and monks, and lashed with merciless severity their doctrines, writings, morals, modes of speech, manners of life, follies, and extravagances, and thus helped in no small degree to bring about the Reformation. The con-

troversy of Reuchlin with the baptised Jew, Pfefferkorn, concerning Hebrew books, gave the first occasion to the *Epistolæ*, and it is probable that their title itself was suggested by the *Epistolæ Clarorum Virorum ad Reuchlinum* (1514). On the first appearance of the work, it was fathered on Reuchlin; afterwards it was ascribed to Reuchlin, to Erasmus, and to Hutten. By many it has been held that Hutten was the chief author, and Crotus Rubianus (q.v.) his chief assistant in the work, which appeared at Hagenau in 1515 or 1516 (but professedly at Venice). But though Hutten certainly wrote the second part (1517), it cannot be said to have been proved that he had any share in the first, of which Crotus Rubianus would accordingly be the chief author, as he certainly was the suggester of the scheme. Inclusion in the *Index Expurgatorius* by a papal bull helped to spread the *Epistolæ* not a little. The numerous editions include Bocking's, with commentary, in his edition of Hutten's works (1869), and F. G. Stokes's, with translation (1909). See D. F. Strauss, *Ulrich von Hutten* (Eng. trans. 1874), Mark Pattison, *Essays* (2 vols. 1889), and W. Brecht, *Die Verfasser der Epist. Obsc. Vir.* (1904).

Epitaph (Gr. *epi*, 'upon,' and *taphos*, 'a tomb'), any commemorative inscription upon a monument. Naturally, brevity and point are the principal things to be aimed at in such memorials, and, as the elemental human emotions are ever the same, we find a striking similarity between ancient and modern epitaphs. The oldest we have are those of the Egyptians, written on the sarcophagi, but these are brief and formal, being merely a record of the name and condition of the deceased, with a prayer to Osiris or Anubis. Quite different are the early Greek epitaphs, which often both in form and substance evince fine literary skill. The earlier examples are mostly in elegiac verse. None are better than those of heroes who have fallen in battle, and of these the classical example is that on the three hundred martyrs to patriotism at Thermopylæ, ascribed to Simonides:

Go tell the Spartans, thou that passest by,
That here obedient to their laws we lie.

The Roman epitaphs usually contain a more or less bare record of facts. On the urns the letters D. M. or D. M. S. (*Dīs Manibus* or *Dīs Manibus Sacrum*) are usually followed merely by the name of the deceased, his age, and condition, with the name of the person who caused the urn to be made. These characters were often adopted from mere conservatism by Christians, and we find them conjoined with purely Christian sentiments in the catacombs at Rome. The ashes of the dead were usually placed along the sides of the great highways leading into Rome, hence the appropriateness of the common commencement, *Siste Viator*—the 'stop passenger' to be seen in so many of our English churchyards. One feature not uncommon in Roman inscriptions was an execration upon the disturber of the sepulchre—the reader will remember that on Shakespeare's tomb at Stratford-on-Avon, most probably from the pen of the great dramatist himself.

Long after the Roman empire had crumbled into ruins, the Latin tongue continued to be used for inscriptions, but in England we occasionally find French used as early as the 13th century. It was hardly, however, till the time of Elizabeth that epitaphs became really literary; then and after we find them written in admirable epigrammatic form by Ben Jonson, Milton, and many others. Pope's English epitaphs were long famous, and also those by Dr Johnson in Latin. The latter's answer to the famous round-robin signed by Gibbon, Burke, Sir Joshua Reynolds, Sheridan, Warton, and others,

requesting that he should write the epitaph for Goldsmith in English, was that 'he would never consent to disgrace the walls of Westminster Abbey with an English inscription.' It is no doubt true that no language lends itself so well to dignity in brief simplicity as the Latin, but the argument from its stability and universality becomes weaker with every generation.

The naturally epigrammatic turn of the French mind peculiarly adapts it for the epitaph, and in French collections very felicitous examples are to be found both in Latin and in French, such as the 'Tandem felix!' of the Count de Tenia; the touching epitaph to a mother, 'La première au rendez-vous'; and that written by Piron for himself after his rejection by the Academy:

Ci-git Piron, qui ne fut jamais rien,
Pas même Academicien.

A large number of the earlier monuments, and consequently of the epitaphs of this country, were destroyed by unfortunate iconoclastic zeal at the Reformation, and after the triumph of the Puritan revolution. The epitaphs to be found in our parish churchyards display every variety of taste, from pure pathos, simplicity, and dignified eulogy to painful would-be wit and even vulgar buffoonery.

See Weever's *Ancient Funerall Monuments* (1631; ed. by Tooke, 1767); Philip Labbe, *Thesaurus Epitaphiorum* (Paris, 1666); De la Place, *Recueil d'Epitaphes* (3 vols. Paris, 1782); Pettigrew's *Chronicles of the Tombs* (1857); Northend, *Book of Epitaphs* (N. Y. 1873); Kippax, *Churchyard Literature: a Choice Collection of American Epitaphs* (1876); Andrews, *Curious Epitaphs* (1883); Unger, *Epitaphs* (1906); Suffling, *Epitaphia* (1300 British; 1909).

Epithalamium, a species of poem which it was the custom among the Greeks and Romans to sing in chorus near the bridal-chamber (Gr. *thalamos*) of a newly-married pair. Sappho, Anacreon, Stesichorus, and Pindar composed poems of this kind, but only scanty fragments have been preserved. The epithalamium of Peleus and Thetis by Catullus is one of the finest specimens of Latin poetry extant; but probably the most splendid epithalamium in all literature is that of our own poet Spenser. Latin examples are extant by Statius, Ausonius, Claudianus, and other poets. A collection of Latin epithalamia is to be found in Wernsdorf's *Poetæ Latini Minores* (4th vol. part 2, Helmst. 1789).

Epithelium is the term applied in anatomy to the cell-tissue which, in layers of various thickness, invests not only the outer surface of the body, and the mucous membranes connected with it—as, for example, those of the nose, lungs, intestinal canal, &c.—but also the closed cavities of the body, such

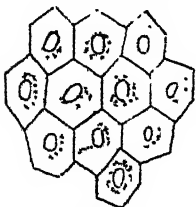

Fig. 1.
Epithelium (still soft like the epithelium of internal parts) of a two months' human embryo. Mag. 350 diam.

Fig. 2.
Epithelial cells of the vessels; the longer one from the arteries, the shorter ones from the veins.

as the great serous membranes, the ventricles of the brain, the synovial membranes of joints, the interior of the heart and of the blood-vessels proceeding to and from it, the ducts of glands, &c. The thickness of this tissue varies extremely with

the position in which it occurs. In some parts it consists of numerous strata of cells, collectively forming a layer of more than a line in thickness; in other parts it is composed of only a few strata, or often of only a single stratum of cells, and can only be detected by the microscope. The cells of which the epithelium is composed are usually soft nucleated cells; they may be rounded, polygonal, fusiform, cylindrical, or conical in shape, and sometimes they possess vibratile cilia. No blood-vessels exist in epithelial tissues, although minute channels may be found between the cells, by means of which the plasma derived from sub-jacent blood-vessels may pass for the nutrition of the cells. In many cases nerve fibrils are abundant.

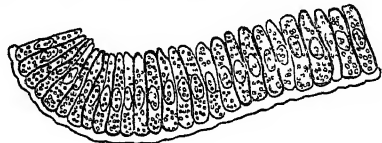

Fig. 3.
Epithelium of the intestinal villi of the rabbit. Mag. 300 diam.

Epithelia may be classified (a) according to the embryonic layer from which they are developed; (b) according to their function; (c) according to their shape and arrangement. Following the latter method, we have (a) *simple epithelium*, consisting of a single layer of cells which may be: (1) *Pavement*, consisting of polygonal plates or scales joined together by their edges. They constitute the variety known as pavement or tessellated epithelium, and occurring as an investment of the serous membranes, of most synovial membranes, of the lining membrane of the heart and of the veins, of the canals of glands, &c. (2) *Columnar or cylinder epithelium*, as in the intestine from the stomach to the termination of the alimentary canal, in the excretory ducts of all the glands opening into the intestine, &c. Illustrations of this cylinder epithelium are given in the article DIGESTION. (3) *Spheroidal or glandular epithelium* is chiefly characteristic of the terminal recesses of secreting glands. (4) *Ciliated epithelium* consists of cells which bear on their free ends spontaneously moving filaments called *Cilia* (q.v.). (b) *Stratified epithelium* consists of cells arranged in many layers, and the individual cells present every variety of shape. As a rule the deepest cells are columnar, and those on the surface flattened and scale-like, but overlapping one another at their margins. It occurs on the anterior

Fig. 4.
Ciliated cells from the finer bronchial tubes. Mag. 350 diam.

Fig. 5.
Stratified pavement epithelium investing a simple papilla (with blood-vessels in the interior) from the gums of a child. Mag. 250 diam.

as the great serous membranes, the ventricles of the brain, the synovial membranes of joints, the interior of the heart and of the blood-vessels proceeding to and from it, the ducts of glands, &c. The thickness of this tissue varies extremely with

surface of the cornea of the eye, in the mouth, pharynx, œsophagus, &c., but its most extensive distribution is in the Epidermis (q.v.). (c) *Transitional epithelium* is intermediate between the forms already described, and may be grouped under the three terms columnar, ciliated, and scaly transitional, according to the kind of cell which is most superficial. In the case of the columnar and ciliated varieties there are smaller cells irregularly disposed between the fixed ends of the large ones, and this constitutes the only difference between these and the columnar and ciliated cells already described.

Scaly transitional epithelium is found lining the urinary Bladder (q.v.) and ureters. The superficial cells are flattened scales when the bladder is distended, but cubical when empty. Moreover, the free surface of the cells is smooth, but on the deep aspect they are moulded over the rounded ends of the pear-shaped cells beneath. Irregular cells fill up the intervals between the tapering ends of the pyriform cells.

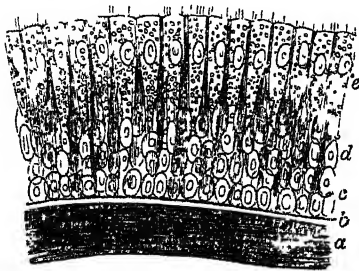

Fig. C.

Ciliated epithelium from the trachea of a man. Mag. 350 diam. a, outermost part of the elastic longitudinal fibres; b, homogeneous outermost layer of the mucous membrane; c, deepest row of cells, d, median long cells; e, outermost conical ciliated cells

In all the varieties of epithelium the layer of external cells is being constantly disintegrated and replaced by the layer immediately beneath. The polygonal or pavement epithelium mainly acts like the epidermis, as a protecting medium to the soft parts beneath. The cylindrical epithelium additionally takes an active part in the process of secretion. Illustrations of the function of the cells forming this variety of epithelium are given in the articles CELL, CILIA, DIGESTION; and the subject will be further noticed under the head SECRETION.

Epizoa, animals that live on the bodies of other organisms in various degrees of parasitism. See PARASITIC ANIMALS, BUG, FLEA, LICE, &c.

Epizootics (Gr. *epi*, 'upon,' and *zōon*, 'an animal') are diseases of animals which manifest a common character, and prevail at the same time over considerable tracts of country. A curious circumstance in connection with them is that they usually follow the same line of route as the diseases of the human race; and, as a rule, when there has been a great epidemic, it has been followed or accompanied by an equally destructive pestilence among animals.

Epoch, in Astronomy, is an abbreviation for 'longitude at the epoch'; it means the mean heliocentric longitude of a planet in its orbit at any given time—the beginning of a century, for instance. The epoch of a planet for a particular year is its mean longitude at mean noon, on January 1, when it is leap-year, and on December 31 of the preceding year, when it is a common year. The epoch is one of the elements of a planet's orbit. For epoch in chronology, see CHRONOLOGY.

Epode is the last part of the chorus of the ancient Greeks, which they sang after the strophe

and antistrophe, when the singers had returned to their original place. The name was applied also to a species of lyric poem invented by Archilochus, in which a longer verse is followed by a shorter one, as the *Epodes* of Horace. See CHORUS.

Eponym (Gr. *epi*, 'on,' and *onyma*, 'a name'), a mythical personage created to account for the name of a tribe or people; thus Tros is the eponymous hero of Troy, Italus was assumed as ancestor of the Italians, &c. For the Assyrian eponym canon, see ASSYRIA.

Epping, an urban district of Essex, in a pleasant healthy situation, at the north end of Epping Forest, 16 miles NNE. of London. It is noted for its cream, butter, sausages, and pork. Population, 4200.—Epping (formerly Waltham) Forest, where kings hunted in olden days, once covered all Essex, and extended almost to London. Inclosures gradually curtailed it from 60,000 acres to 12,000 in 1793, and to less than 4000 in 1871, when (the government refusing to stir in the matter) the corporation of London undertook the preservation of all that was left, and the recovery of the more recent inclosures. As an outcome of their exertions, and at a cost of about half a million, 5600 acres of Epping Forest were declared free to the public by Queen Victoria on 6th May 1882. Reached easily from Loughton, Chingford, and other stations, Epping Forest is still a glorious place alike for naturalist and mere holiday-maker. Its 9 square miles of almost unbroken woodland, which at High Beech or Queen Victoria's Wood attain a height of 379 feet above sea-level, form one of the finest pleasure-grounds in Europe. Separated by a stream from Epping Forest is Hainault Forest (the 'garden fair' of Sir W. Besant), disafforested in 1851, and added to Epping Forest for public use in 1906. Here, till 1820, stood Fairlop Oak, the scene of a July fair, as famous in its way as the old Epping stag-hunt on Easter Monday. See E. N. Buxton, *Epping Forest* (1884; new ed. 1911); and works by Fisher (1887), Perceval (1909), and Southern (1916).

Éprouvette is a machine for proving or testing the strength of gunpowder. The *gun éprouvette* does this by measuring the amount of recoil produced on a small gun swung like a pendulum; the *mortar éprouvette* by measuring the distance to which a ball is projected. A third pattern is shaped like a small pistol, with an extremely short barrel, closed by a flat plate connected with a strong spring. On firing, the plate is driven back to a distance indexed according to the strength of the powder.

Epsom, an urban district of Surrey, on the margin of the Banstead Downs, 15 miles SSW. of London. The sulphate of magnesia springs, which made Epsom so fashionable a resort in the later half of the 17th century, gave name to the Epsom salt formerly manufactured from them. The church, rebuilt in 1824, contains monuments by Flaxman and Chantrey. The Royal Medical College (1851), on the Downs, provides education for the sons of medical men and others, and affords a home to decayed members of the profession and their widows. Population, about 20,000. On the Downs, 1½ mile S. of the town, the famous horse-races are held yearly (see DERBY DAY, HORSE-RACING). The grand stand (1830, enlarged 1886) accommodates 7500 spectators.

Epsom Salt, or SULPHATE OF MAGNESIA, $MgSO_4 \cdot 7H_2O$, was originally obtained by evaporating the waters of the springs at Epsom. It was soon found that sea-brine also contained large quantities, and the manufacture at Epsom was therefore given up. It is found native in various

parts of America and elsewhere. In England, as well as in America, varieties of magnesian limestone are extensively treated with sulphuric acid for its production.

Epsom salt forms small needle-like crystals, which have a bitter saline taste and neutral reaction. It is a well-known useful purgative medicine, acting as a refrigerant, and sometimes as a diuretic. Its disagreeable bitter taste may be relieved by the addition of a little sulphuric acid (as in Henry's solution) or syrup of lemon. It is of importance that plenty of water be drunk along with it (one or more tumblers). See MAGNESIUM.

Epstein, JACOB, sculptor, was born at New York, of Russian-Polish parents, on 10th November 1880. Educated in Paris, he settled in England in 1904, and in 1907 first gained prominence by his much-discussed figures for the new buildings of the British Medical Association in the Strand. His busts are now almost universally recognised as masterpieces of the first quality, but storms of criticism have raged round his symbolic work. In this last kind are his 'Oscar Wilde Tomb' at Père Lachaise, Paris; his 'Sun God,' 'Venus,' 'Mother and Child,' 'Maternity,' and his 'Christ.' See B. van Dieren, *Epstein* (1920).

Epworth, a market-town of Lincolnshire, in the 'Isle' of Axholme, 10 miles NNW. of Gainsborough. The great John Wesley was a native, as well as Alexander Kilham, founder of the Methodist New Connection. Pop. 2000.

Equations. The statement in symbols of the relationship of equality existing between two algebraic expressions is termed an equation. Such expressions generally contain at least one unknown quantity. Thus $x - 2 = 4 + 3$ is an equation denoting that if 2 be deducted from some unknown quantity denoted by x , the remainder will be equal to $4 + 3$, that is 7; therefore the value of x in this equation is evidently $7 + 2$, or 9. Any equation in one variable x may be reduced to a form such as $F(x) = 0$, where $F(x)$ is a function of x , and this may be considered as the standard form of all equations. When written fully in the most general manner, this may be said to be equivalent to the equation

$$a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-2}x^2 + a_{n-1}x + a_n = 0.$$

This is said to be an equation in x , the variable involved; $a_0, a_1, a_2, \dots, a_n$ are the coefficients, either numerical or algebraical quantities. Any quantity which, when substituted for x , reduces the left-hand side to zero—i.e. any quantity which satisfies the equation, is termed a *root* of the equation. The main problem in equations is that of finding all the possible roots; this done, a *complete solution* is obtained. The theory of equations is a most important branch of algebra.

Identical equations are those which are always true, whatever be the value of the quantities involved; *conditional* equations are satisfied only by certain values for x . Equations are usually classified according to their *degree*, which is defined as being the highest degree of the involved variable. The equation written above as the standard form is, for example, of the n th degree. Simple equations, or equations of the first degree, are those in which x or the unknown quantity appears only in the first power; when x appears in the second power, the equation is quadratic; when x is in the third power, cubic, and so on. Equations of the first, second, third, fourth, fifth, &c. degrees are sometimes called linear, quadratic, cubic, quartic (or biquadratic), quintic, &c. equations.

Equation in astronomy means the corrections or reductions which must be applied to observations

in order either to free them from error or otherwise to reduce them to some form more suitable for purposes of calculation. For the *Equation of Time*, see the article DAY. *Personal equation* is a correction which has to be applied to astronomical (or other) observations in order to remove relative error due to some peculiar mode of observation on the part of the observer. In astronomical observatories it is the practice to find this personal equation for all the observers with reference to one single observer, and the observations are all reduced by its application, so that finally they are tabulated as if made by one observer. The phrase has passed into common language, and is often used to denote that modification which is requisite in the statements or judgments of any person who in such matters is not free from bias or idiosyncrasy. There are also *equations to the centre*, allowing for the difference between the place of a planet as supposed to move in a circle and its actual place in an ellipse; and *equations of equinoxes*, between mean and apparent equinoxes. *Equation of payments* is an arithmetical rule for ascertaining at what time it is equitable for a person to pay a whole debt which is due in different parts, payable at different times. Equations are constantly used in Chemistry (q.v.).

Equator. The Terrestrial Equator is the great circle on the earth's surface dividing the earth into the northern and southern hemispheres, and halfway between the poles.—The Celestial Equator is the great circle in the sky corresponding to the extension of the equator of the earth.

Equatorial, an important instrument for observing and following a celestial body in any part of its diurnal course. It consists, in the usual form, of two axes, one fixed square across the end of the other, thus T. The cross axis (called the *declination axis*) revolves in bearings fixed to the upright one (called the *polar axis*), which again turns in bearings supported by a fixed pillar, resting on a solid foundation. Across one end of the cross axis is rigidly fixed a telescope, and on the other end slides a counterbalancing weight. Thus the telescope can be turned freely in any direction, and clamped by suitable mechanism. As erected for use, the upright axis is fixed to point directly to the pole of the heavens. It being then revolved, the other axis will trace with its ends the line of the celestial Equator (q.v.). By this motion the telescope sweeps the sky from east to west, and by rotating the cross axis it sweeps from north to south. The amount of rotation of each axis is measured by a graduated circle fixed to it, and thus the position of any heavenly body observed is known. Conversely, by setting the circles and observing the time, the telescope may be set so as to point to any star, even if it be one invisible to the naked eye. The hour circle, on the polar axis, measures the right ascension of the star, and the other, or declination circle, its declination. The equatorial can hardly be called an astronomical instrument. It is rather a convenient method of mounting large astronomical telescopes. For if the telescope be pointed to any star and clamped, while the *polar axis* is regularly revolved by clockwork, the star remains steadily in the field of view. See TELESCOPE.

Equerry, an official under the Master of the Horse (see HORSE, MASTER OF THE), who accompanies the sovereign when riding in state.

Equestrian Order, or **EQUITES**. This body originally formed the cavalry of the Roman army, and is said to have been instituted by Romulus, who selected from the three principal Roman tribes 300 equites. This number was afterwards gradually increased to 3600, who were partly of patrician and partly of plebeian rank, and required to

possess a certain amount of property. Each of these equites received a horse and 'barley-money' from the state; but about 400 B.C. a new body of equites began to make their appearance, who were obliged to furnish a horse at their own expense, although they received regular pay. These were probably wealthy *novi homines*, men of equestrian fortune, but not descended from the old equites. Until 123 B.C. the equites were exclusively a military body; but in that year a measure was carried transferring the judicial functions from the senate to the equestrian body, which now became a distinct order or class in the state, and was called *Ordo Equestris*. In 70 B.C. Sulla deprived them of these powers; but their influence did not then decrease, as the farming of the public revenues had fallen into their hands (see *PUBLICANI*); and after Sulla's death they shared their former privilege with the senate. In Diocletian's time the civil and military power in the provinces passed from the senate to the equites. Under later emperors, when the requisite fortune of an eques seems to have been about £3230, the state still furnished horses for what was no longer the national cavalry; but as the honour, indiscriminately conferred, fell into contempt, foreign auxiliaries took the place of the old knights, and the body gradually became extinct. See Clinton Walker Keyes, *The Rise of the Equites in the 3rd Century of the Roman Empire* (1915).

Equidæ. See HORSE.

Equilibrium, the state of rest or balance of a body or system, solid or fluid, acted upon by various forces. See *STATICS*, and *HYDROSTATICS*.

Equinia. See *GLANDERS*.

Equinoctial is the same as the celestial Equator (q.v.). The equinoctial points are those in which the equinoctial and the Ecliptic (q.v.) intersect. Equinoctial time is time reckoned from the moment in each year when the sun passes the Vernal Equinox (see *EQUINOXES*). This instant is selected as a convenient starting-point of a uniform reckoning of time for the purposes of astronomical observers.

Equinoctial Gales. One of the most widespread beliefs in, at least, the British Islands is that there occurs an unusual frequency of gales and storms about the times of the spring and autumn equinoxes. This belief is, however, unsupported by the records of carefully conducted observations. Thus at Gordon Castle, in Strathspey, upwards of fifty years' observations show, on the contrary, fewer storms on the five days from the 21st to the 25th of March and September than on the five days preceding and the five days following these dates. Long-continued observations at other places are equally decisive against the popular belief.

Equinoxes. Sometimes the Equinoctial Points (see *EQUINOCTIAL*) are called the equinoxes. More commonly, by the equinoxes are meant the times when the sun enters those points—about 21st March and 22d September, the former being called the Vernal or Spring Equinox, and the latter the Autumnal. When in the equinoxes, the sun, through the earth's rotation on its axis, seems to describe the circle of the equator in the heavens, and the days and nights are of equal length all over the world. At the vernal equinox, the sun is passing from south to north, and in the northern hemisphere the days are lengthening; at the autumnal, he is passing from north to south, and the days are shortening. As the earth moves more rapidly when near the sun, or in winter, the sun's apparent motion is not uniform, and it happens that he takes eight days more to pass from the vernal to the autumnal equinox than

from the latter to the former. The equinoctial points are not stationary. See *ECLIPTIC*, *PRECESSION*.

Equisetaceæ. See *HORSE-TAIL*.

Equity, *EQUITABLE RIGHTS*, &c. Equity (Lat. *æquitas*) signifies moral justice, of which laws are the imperfect expression; or the spirit of justice which enables us to apply and interpret laws rightly. Thus, the equity of a statute means the fair and wise construction of it, according to the intention of parliament, as distinguished from the literal and technical construction of the words used. It is impossible that any system of positive law should provide a rule suited to every case that arises; even good laws may work injustice, unless they are interpreted by men having discretion and authority to control their rigour and supply their deficiencies. In the Old Testament and in the New, we constantly meet with the distinction between form and substance, between the letter which killeth and the spirit which maketh alive. The early Roman law was, like that of Moses, a system of forms and ceremonies; but the prætors, who had jurisdiction in commercial cases, soon found it necessary to go beyond the limits of custom and tradition. They assumed the *nobile officium* of deciding in accordance with equity; and their decisions formed the *jus honorarium* (magistrate's law, as distinguished from the customary law of the people). Courts of equity do not exercise an arbitrary discretion; they proceed on principles. The prætor, on entering upon his office, published an edict, setting forth the principles by which his judicial conduct would be guided; and as each prætor naturally adopted what was sound in the edicts of his predecessors, a system of equity was gradually developed. Ultimately, in the reign of Hadrian, the edicts of the prætors were consolidated in a single document called the *Perpetual Edict*.

In England, all the courts apply equitable principles in construing statutes and formal instruments; but the term equity has acquired a peculiar importance, by reason of the part which the Court of Chancery (q.v.) took in supplementing and controlling the rules of the common law. The common lawyers protested against the arbitrary nature (as it seemed to them) of equitable jurisdiction; they said that equity meant only the length of the chancellor's foot. But before the end of the 17th century this reproach was removed; the rules of equity were reduced to a system; and the Chancery jurisdiction was firmly established. The powers of the court were of three kinds: 1. *Exclusive*, as in the administration of trusts. When the legal ownership of property was conveyed to a trustee, he was the only person whom a court of law could recognise as owner; but a court of equity would protect the equitable estates of the persons beneficially entitled (see *TRUST* and *USE*). 2. *Concurrent*, in cases where law and equity both provided a remedy. Thus, in a case of breach of contract, the law would give damages to the party wronged; but equity could, in a proper case, go further, and compel specific performance of the contract. 3. *Assistant*, where equity only interfered to make legal process more effective. Courts of law, for example, formerly refused to allow a party to be called as a witness; a court of equity would order a party to make discovery to his opponent of such facts as the opponent had a right to know.

The principles of equity, as applied by the Court of Chancery, are summed up in certain maxims of wide significance: 'Equity follows the law'—i.e. equity will not set aside a rule of law (such as the rule of primogeniture), but will seek to apply

existing rules in a spirit of justice. 'Equity assumes that to be done which ought to be done:' when, for example, a man sells his land, equity treats the purchaser as owner, even before the formal conveyance has been executed. When a man deposits the title-deeds of his land with a banker, in consideration of a loan, this is a good Equitable Mortgage; the borrower is not allowed to plead the absence of a written agreement as an excuse for withdrawing from the transaction; equity will even compel him to execute a formal mortgage, if the lender requires it. 'Equity looks to the substance, and not to the form:' a legal mortgage of land, for example, is, in form, an absolute conveyance; but equity treats it as a security for money. The mortgagee is legal owner; but the mortgagor retains his Equity of Redemption—i.e. his right to have the estate again on paying principal and interest of the loan. 'He who seeks equity must do equity'—e.g. a mortgagor seeking to redeem must pay off all incumbrances held by the mortgagee who has the legal estate.

It is difficult to overestimate the advantages gained by the application of equitable principles to the law of property and contract. But these advantages were counterbalanced in England by the defects of Chancery procedure, and the inconvenience caused by the existence of two sets of courts, applying different rules to the same subjects. Chancery reform has now removed the scandals of the old system. Equitable powers were conferred on the courts of common law by Acts for the improvement of procedure. Finally, the Judicature Acts, which came into force in 1875, effected a fusion of law and equity, so that in every branch of the Supreme Court equitable claims may be made, and equitable defences pleaded. Law and equity are administered concurrently; where they conflict, the rules of equity prevail. Certain classes of business, relating to trusts, mortgages, property of infants, &c., are reserved to the Chancery Division of the High Court of Justice.

In America, and in the British dominions, the distinction between law and equity is or has been recognised as in England. In Scotland, the *nobile officium* of the Roman prætor is exercised by the Court of Session. For an outline of the English system, see Snell's *Principles of Equity*.

Equivalents, in Chemistry. See ATOMIC THEORY.

Era. See CHRONOLOGY.

Eradicated, in Heraldry, is said of a tree, or part of a tree, torn up by the roots.

Érard, SÉBASTIEN, French musical instrument-maker, chiefly famous for his improvements and inventions in connection with the pianoforte and harp, was born at Strasburg on 5th April 1752. Proceeding to Paris when sixteen, he shortly afterwards started business as a pianoforte-maker in that city, constructing his first pianoforte, one of the earliest made in France, in 1776 or 1777. The outbreak of the Revolution drove him to London; but in 1796 he returned to Paris. From 1808 to 1812 he was again in London. He died near Passy on 5th August 1831. He was the inventor of the harp with double pedals, and he also improved the sound-body of the instrument. The pianoforte with double escapement was likewise invented by Érard.

Erased.

Erased, in Heraldry, signifies violently plucked or torn off, and showing a ragged edge; as opposed to couped or cut, which shows a smooth edge. The term is chiefly applied to the heads and limbs of animals.

Erasi'stratus, one of the most famous physicians and anatomists of ancient times, was born in the island of Ceos about 300 B.C., settled in Alexandria, and died in Asia Minor. He founded a school of medicine, wrote several works on anatomy—in which branch he was most celebrated—on practical medicine, and pharmacy. He believed that the heart was the origin both of the veins and arteries. Of his numerous writings only some obscure fragments and titles have been preserved. See the article ANATOMY; and Hieronymus, *Erasi'strati et Erasistrateorum Historia* (Jena, 1790).

Erasmus, DESIDERIUS, was born at Rotterdam, probably in the year 1467, the date given on the pedestal of his statue in his native town. A reference in his own works, however, as also his epitaph at Basel, assigns the date 1466. He was the son of one Gerhard, and Margaret, the daughter of a physician. As of illegitimate birth, he had no surname; and the name by which he is known, Desiderius Erasmus, is but the rendering in Latin and Greek of *Gerhard* ('the beloved'). Erasmus first attended school at Gouda, but while still a mere child he was sent to Utrecht, to fill a place in the choir of the cathedral of that city. He was next removed to a famous school of that time—that of the 'Brothers of the Common Life,' at Deventer, where, by his own account, he was exercised mainly in composing, repeating, and learning the silliest Latin verses. The study of Greek had as yet made but slight progress out of Italy; but Erasmus was fortunate in receiving some little instruction in that language from Alexander Hegius, the head of Deventer school, and a scholar of considerable reputation. An outbreak of the plague, of which his mother died, led to his quitting this school and retiring to Gouda, the residence of his father. Gerhard dying soon after, Erasmus and his only brother were left to the care of three trustees, who grossly neglected their charge. One of the three was bent on the brothers' entering a monastery, and with this in view, instead of sending them to a university, for which they were now ripe, placed them at another school of the Brothers of the Common Life at Bois-le-Duc. Again the plague drove Erasmus to Gouda, where his guardians tried every means to persuade him and his brother to become monks. As a compromise, Erasmus agreed to enter the Augustinian college of Sion, near Delft, on the condition that it should be left to him to leave the college if he saw fit. Here, accordingly, for the next six years he lived the life of a monk, though in his case the discipline was somewhat relaxed in the hope of his being induced eventually to adopt the monastic life. It was undoubtedly this personal experience of the ways of living and thinking of the monks that made Erasmus their relentless and lifelong enemy.

Deliverance at length came to him from the Bishop of Cambrai, who engaged him as his private secretary, and undertook to provide him with means to prosecute his studies. A few months later, and after having taken priest's orders, Erasmus went to Paris, supplied, though not over-liberally, with funds by the bishop. The Collège Montaigu, where he pursued his studies, was notorious among all the colleges of Paris for the severity of its discipline, the scantiness and wretchedness of its fare, and the general squalor of its domestic arrangements. The new studies of the Renaissance had as yet made but little way in Paris; but Montaigu above every other college was still fast in the bonds of scholasticism. To Erasmus, therefore, whose constitution was delicate to fragility, and who from the very outset seems to have been awake to the intellectual revolution that had come upon Europe, all his surroundings in

Paris at this time were in the highest degree distasteful. To the end of his life he never forgot his experiences at Montaigu; and not the least important of his subsequent achievements was the service he did in helping to discredit the frivolous dialectic which he had there seen in its most absurd form.

With the exception of a visit to the Bishop of Cambrai on account of his health, Erasmus resided mainly in Paris till 1498, gaining a livelihood by instructing private pupils. Of these pupils, Lord Mountjoy deserves special mention, as he always remained one of Erasmus's best friends and most generous patrons. It was on the invitation of Mountjoy that Erasmus, probably in 1498, paid his first visit to England. This visit is one of the most important epochs in the life of Erasmus. Oxford was the chief place of his residence, and there he not only had in Linacre a better teacher of Greek than he could have found in Paris, but in his intercourse with Colet, a man of nobler stamp than himself, he received an impetus, which if it did not actually give a new bent to his studies, at least lifted his life to a higher plane of endeavour. Through the influence of Colet, his contempt for the schoolmen was intensified, and his thoughts set on the consecration of his studies to a more rational conception of religious truth. During this visit, also, began his famous friendship with Sir Thomas More, through whom on the present occasion he was introduced to Prince Henry (afterwards Henry VIII.), then only a boy of nine.

In 1500 Erasmus was again in France, and for the next six years he made his abode mainly in Paris, with occasional visits of longer or shorter duration to Orleans, and in the Low Countries. To these years belong his *Adagia* (afterwards published in greatly enlarged form in 1515), a collection of Greek and Latin proverbs, with running commentaries, and his *Enchiridion Militis Christiani* (The Christian Soldier's Dagger). A second short visit to England in 1506 cemented still more closely his friendship with More, and gained him a valuable friend in Warham, Archbishop of Canterbury and Lord Chancellor of England. During the same year he carried out a journey to Italy, which for long had been his passionate desire. At Turin he received the degree of Doctor of Divinity; at Bologna he witnessed the military triumph of the bellicose Pope Julius II.—a spectacle which Erasmus always spoke of as a disgrace to Christian Europe; and at Venice he made the acquaintance of the famous printer Aldus Manutius. During his sojourn in Italy he acted for some time as tutor to Alexander, Archbishop of St Andrews, natural son of James IV. of Scotland, who afterwards fell with his father at Flodden. His visit closed with a short stay in Rome, where he was received in a manner that proves the great reputation he had already won in letters. Altogether, as was to be expected from the different temper and aims of the two men, Erasmus carried away from Italy a far more friendly impression than Luther after his memorable visit about the same date. The accession of Henry VIII., of whom great things were expected as a patron of learning, and the special invitation of Lord Mountjoy, induced Erasmus once more to make his home in England. On his journey from Italy to that country he conceived the plan of his *Encomium Morie* (Praise of Folly), which on his arrival he threw upon paper in the course of a week. In this satire, written in the full maturity of his powers, we have Erasmus in his happiest and most distinctive vein, as the man of letters and the general critic of men and things. While its general tone is that of playful banter, it is yet inspired by the most serious purpose, as specially appears in its biting sarcasm at the

expense of kings and churchmen. Seven editions of this work were issued within a few months.

During this his third and longest visit to England, Erasmus resided chiefly in Cambridge, where he acted as Margaret professor of Divinity, and professor of Greek. After 1514 Erasmus's changes of abode for the next few years are so frequent that it becomes puzzling to follow him. In 1514 he was in Basel, back in England the same year, again in Basel in 1515, and once more in England—the last of his visits to that country. From 1517 to 1521 he lived at Louvain, taking a keen interest in the progress of the new studies at the famous university of that place. Meanwhile, his literary labours were unceasing. In 1519 appeared the first edition (afterwards greatly enlarged) of his *Colloquia*, the most famous of all his works, and usually regarded as his masterpiece. It consists of a series of familiar dialogues on the everyday topics of the time—social, religious, and political; and the audacity and incisiveness with which it handles the abuses of the church in large measure prepared men's minds for the work of Luther. In 1516 his edition of the New Testament, virtually the first of the Greek text, was published at Basel; and in 1519 his edition of St Jerome in nine folio volumes. In both of these works the dominant aim of Erasmus was to introduce a more rational conception of Christian doctrine, and to emancipate men's minds from the frivolous and pedantic methods of the scholastic theologians. By such labours, as by his *Adagia* and *Encomium Morie*, Erasmus had shown the need for a general reform in the church. When the Lutheran revolution came, therefore, Erasmus found himself in the most embarrassing position. The upholders of the old order fell upon him as the author of all the new troubles, and the followers of Luther, on the other hand, bitterly assailed him for what they deemed his cowardice and inconsistency in refusing to follow up his opinions to their legitimate conclusions.

From the date of Luther's final breach with Rome, the life of Erasmus was one long controversy, which seriously marred the honour and happiness of his declining years. In 1521 he left Louvain, where the champions of the old faith had made his stay unendurable, and took up his abode at Basel. In this city, with the exception of a sojourn in Friburg from 1529 to 1535, Erasmus spent the rest of his life. To Basel he had always been attracted as the home of the great printer Froben, as well as by the excellence of its climate, and he now found it the quietest spot in the general din of religious strife. To the very last his labours were incessant and almost incredible. In addition to the toil of editing a long succession of classical and patristic writers, he was engaged in controversies which would have incapacitated most men for peaceful study. The most important of these controversies were those with Ulrich von Hutten, with Luther, and with the Sorbonne. In accordance with his fiery character, Hutten judged Erasmus with the greatest severity for not taking his place by the side of Luther. With the great Reformer himself, Erasmus, after long hesitation, crossed swords in his *De Libero Arbitrio* (1523), in which he assailed one of the fundamental positions of the Lutheran theology—that all human action is determined by divine necessity. Attacked by men like Hutten on the one side, he was as fiercely assailed on the other by the Sorbonne, the great surviving stronghold of obscurantism alike in theology and secular studies. By his *Ciceronius*, a satire on the pedantic imitation of Cicero, Erasmus raised against himself a new set of adversaries—those humanists, namely, who set style above matter. Yet in spite of all these contro-

versies, Erasmus during his last years enjoyed fame and consideration beyond that of any man of letters before or since. Letters and presents came to him from all the crowned heads of Europe; and churchmen in the highest position deemed it an honour to be among his correspondents.

Erasmus's health had never been robust even in youth, and from a comparatively early age he had been afflicted with the stone. As he advanced in life, his sufferings grew upon him, and it was only by the most careful ordering of diet, and by his overpowering instinct for study, that he accomplished the work he did. From 1534, a disease resembling gout in its symptoms subjected him at times to excruciating pain. On 12th July 1536, after nearly a month's attack of dysentery, he died, retaining to the last his gay and genial humour.

Erasmus stands as the supreme type of cultivated common sense applied to human affairs. In his latter years he fell upon a time when other qualities were needed in the best interests of humanity; but such as he was, few men have done more to advance truth, and to prepare men's minds for its acceptance. No man of letters has ever attained to anything approaching the influence wielded by Erasmus during his own century. Yet Erasmus was no creative genius, and he produced no single work which has a place in the first rank of the world's masterpieces. He owed his position to the wonderful range of his activity, to his astonishing productiveness, to the breadth and sanity of his views, and to the delightful qualities of wit, humour, and unfailing vivacity which distinguish all his work. He has himself indicated his services to Europe with exactness and precision. He rescued theology from the pedantries of the schoolmen, and referred it to its original sources; he did more than any other single person to advance the cause of the new studies of the Revival of Learning; he exposed the abuses of the church, and he protested in the interests of the people against the thoughtless tyranny of their rulers. His attitude towards the Lutheran revolution has exposed him to the obloquy of Protestants and Catholics alike. By both he has been accused of cowardice and insincerity, because he insisted in maintaining his neutral position. But this is merely to say that Erasmus had the defects of his qualities. Constitutionally, he was averse to all extremes, as he distinctly showed in his antagonism to the excesses of humanism in its neo-pagan developments, not less than to what he considered the excesses of the German Reformation. If he had not the energy to head a revolution, he had at least in eminent degree the courage of the scholar, as the long catalogue of his works, produced in chronic weakness of health, amply proves. As to his personal qualities, it should be sufficient to say that he enjoyed the friendship and esteem of men of so different, yet each in his own way of so high a type, as Bishop Fisher, Colet, and More. His personal appearance corresponded to his mental and moral qualities. He was slightly under the middle height, but of graceful figure; his features were delicate and mobile; and he spoke in tones low but beautifully clear and distinct.

An edition of his works was published at Basel in 9 vols. in 1540; the standard edition is that of Le Clerc (Lyons, 10 vols. 1703-6). See Lives by Knight (1726), Jortin (1748), Burigny (1752), Durand de Laur (1874), Drummond (1873), Feugère (1874), Froude (1894), Allen (1914), Huizinga (1924), Preserved Smith (1924); a book by Amiel (1889); his Letters (ed. Allen, 1906 *et seq.*; trans. Nichols, 1918).

Erastus, THOMAS (properly *Liebler* or *Lieber*), theologian and physician, was born in 1524, probably at Baden in Switzerland, but possibly at Auggen,

near Mühlheim in Württemberg. He studied theology at Basel (where he Grecised his name), and philosophy and medicine at Bologna and Padua. After nine years in Italy he was appointed physician to the counts of Henneberg, then (from 1558) professor of medicine at Heidelberg, and court-physician to the Elector Palatine. He removed from Heidelberg to fill the chair of Medicine at Basel in 1580, and died there, January 1, 1583. Shortly before his death he had been appointed professor of Ethics. Erastus was a skilful physician and a man of upright character, an equally vigorous writer against 'the new medicine of Philip Paracelsus' (1572) and in favour of the burning of witches (1577 *et seq.*). In theology he was a follower of Zwingli, and represented his view of the Lord's Supper at the conferences at Heidelberg in 1560 and Maulbronn in 1564. The fame of Erastus now rests on his strenuous opposition to Calvinist discipline and Presbyterian order. For ten years (from 1560) he resisted successfully the Calvinist party under Caspar Olevian at Heidelberg; but in 1570 Presbyterianism was introduced by the Elector Frederick III. Erastus was excommunicated on a false suspicion of heresy, founded on a correspondence with Unitarians of Transylvania, but was restored in 1575. He had carried on a private exchange of views on the subject of church discipline with his friend Beza, and after his death his widow's second husband, Castelvetro, published at London (1589), with the concurrence of Archbishop Whitgift and with a fictitious imprint, a treatise on excommunication entitled *Explicatio gravissimæ quæstionis utrum Excommunicatio . . . mandato naturæ divino, an excogitata sit ab hominibus*. This was answered by Beza in his *De verâ Excommunicatione et Christiano Presbyterio* (1590). A translation of Erastus's treatise was published with a preface by Dr Robert Lee (Edin. 1844). Erastus maintained that no member of the church should be excluded from her communion as a punishment for sin. Punishment is 'the special duty and office' of the civil magistrate. He was familiar with the system of Zurich, where the Christian magistrate administered ecclesiastical discipline in the name of the Christian community, and he dreaded that Presbyterianism, unchecked, might exercise a tyranny over men's consciences as absolute as that of the Spanish Inquisition.

In England, the name of Erastians was applied to the party that arose in the 17th century, denying the right of autonomy to the church—a right neither maintained nor denied by Erastus. The Erastian controversy broke out at the time of the Westminster Assembly. The leading Erastians in that assembly were Lightfoot and Coleman, who were supported by Selden and Whitelocke in the House of Commons. Since the time of the Reformation the controversy has been confined chiefly to the church in Scotland.

See on the one side, Gillespie, *Aaron's Rod Blossoming* (1646), Sam. Rutherford, *Divine Right of Church Government* (1646), and Cunningham's *Historical Theology*, vol. ii. chap. xxvii. (1863); and on the other, Selden, *De Symedriis* (1650-53), and Du Moulin, *Of the Right of Churches* (1658).

Erasure, or **RAZURE**, as it is more commonly called in England, from the Latin *rado*, 'I scrape or shave,' is the scraping or shaving of a deed or other formal writing. In England, except in the case of a will, the presumption, in the absence of rebutting evidence, is that the erasure was made at or before execution. If an alteration or erasure has been made in any instrument subsequent to its execution, that fact ought to be mentioned (in the abstract, or epitome of the evidences of ownership), together with the circumstances under which

it is done. A fraudulent alteration, if made by the person himself taking under it, would vitiate his interest altogether. It was formerly considered that an alteration, erasure, or Interlineation (q.v.) would void the whole instrument, even in those cases where it was made by a stranger; but the law is now otherwise, as it is clearly settled that no alteration made by a stranger will prevent the contents of an instrument from retaining its original effect and operation, where it can be plainly shown what that effect and operation actually was. To accomplish this, the mutilated instrument may be given in evidence as far as its contents appear; and evidence will be admitted to show what portions have been altered or erased, and also the words contained in such altered or erased parts; but if, for want of such evidence, or any deficiency or uncertainty arising out of it, the original contents of the instrument cannot be ascertained, then the old rule would become applicable, or, more correctly speaking, the mutilated instrument would become void for uncertainty. If a will contains any alterations or erasures, the attention of the witnesses ought to be directed to the particular parts in which such alterations occur, and they ought to place their initials in the margin opposite, before the will is executed, and to notice this having been done by a memorandum, added to the attestation clause at the end of the will. For the English law on this subject, see Taylor, *Law of Evidence*.

In Scotland, the rule as to erasure is somewhat stricter than in England—the legal inference being that such alterations were made after execution. As to necessary or *bona fide* alterations which may be desired by the parties, corrections of clerical errors, and the like, after the deed is written out, but before signature, the rule in Scotland is that 'the deed must show that they have been advisedly adopted by the party; and this will be effected by mentioning them in the body of the writing. Thus, if some words are erased and others superinduced, you mention that the superinduced words were written on an erasure; if words are simply delete, that fact is noticed; if words are added, it ought to be on the margin, and such additions signed by the party, with his Christian name on one side, and his surname on the other; and such marginal addition must be noticed in the body of the writ, so as to specify the page on which it occurs, the writer of it, and that it is subscribed by the attesting witnesses.' See Menzies's *Lectures on Conveyancing*. The Roman rule was that the alterations should be made by the party himself, and a formal clause was introduced into their deeds to this effect, 'Lituras, inductiones, superinductiones, ipse feci.' As a general rule, alterations with the pen are in all cases to be preferred to erasure; and suspicion will be most effectually removed by not obliterating the words altered so completely as to conceal the nature of the correction. 'The worst kind of deletion,' says Lord Stair, 'is when the words deleted cannot be read (but if they are scored that they can be read, it will appear whether they be *de substantialibus*), for if they cannot be read, they will be esteemed to be such, unless the contrary appear by what precedes and follows, or that there be a marginal note, bearing the deletion, from such a word to such a word, to be of consent.' The law of the United States follows that of England in this matter.

ERATOSTHENES OF CYRENE, born 276 B.C., was an eminent mathematician, astronomer, and geographer. Among his teachers were Lysanias the grammarian and Callimachus the poet. By Ptolemy Energetes he was called to Alexandria to superintend his great library. Here he died of

voluntary starvation, at the age of eighty, having become blind, and wearied of life. Eratosthenes measured the obliquity of the ecliptic with an accuracy wonderful for his time, drew up a catalogue of the fixed stars, amounting to 675, which is now lost, and made an attempt to measure the magnitude of the earth in the method used at the present day. He found the circumference of the earth to be 252,000 stadia, which, according to Pliny, is 31,500 Roman miles. His most important work was a systematic treatise on geography, which was used by Strabo. He wrote also on moral philosophy, history, and grammar. Such fragments of his writings as are still extant have been collected by Bernhardt in his *Eratosthenica* (Berlin, 1822). See also Beiger, *Die geographischen Fragmente des Eratosthenes* (Leip. 1880).

Erbium (Er; atom. wt. 168) is a rare metal, the compounds of which are present in the mineral *ytterbite* or *gadolinite*, found at Ytterby in Sweden. It is also believed to be present in the sun's vapour. Its salts exhibit signs of radioactivity. The ytterbite metals include erbium, ytterbium, and others, the existence of some of which was till recently in doubt. It is chiefly of interest because the compounds of the three metals mentioned resemble each other so closely, and have such similar properties, that the processes of separation and purification are difficult and tedious in the extreme, a single research with the object of obtaining absolutely pure salts requiring years of patient work.

Ercildoune. See EARLSTON.

Ercilla y Zúñiga, ALONSO, a Spanish poet, was born at Madrid, August 7, 1553. He became page to the Infante Don Philip, son of Charles V., and accompanied him on his early travels, and in 1554 to England, on the occasion of Philip's marriage to Queen Mary. Shortly after he joined the expedition against the Araucanians on the coast of Chili. The arduous difficulties that had to be overcome, and the heroism of the natives, suggested to Ercilla the idea of making it the subject of an epic poem. He began his poem on the spot, about the year 1558, occasionally committing his verses, in the absence of paper, to pieces of leather. An unfounded suspicion of his having plotted an insurrection involved him in a painful trial, and he had actually ascended the scaffold before his innocence was proved. Deeply wounded, the brave poet-soldier turned to Spain, but Philip treating him with great coldness and neglect, he made a tour through France, Italy, Germany, Bohemia, and Hungary. For some time he held the office of chamberlain to the Emperor Rudolf II., but in 1580 returned to Madrid, where he struggled with poverty till his death, about 1595. Cervantes in *Don Quixote* compares the *Araucana* with the best Italian epics, and it has undoubtedly not a little of the epic style and spirit. The first part is the freshest in character, and was published in 1569; the second part followed in 1578, the third in 1597. A very elegant reprint appeared at Madrid in 1776. Facsimiles of the original editions were published at New York in 1902-3. There is a French translation by Nicolas (1870). See Royer's *Étude* (Dijon, 1880).

Erckmann-Chatrian, the compound name of two French romancists, Lorrainers both, whose stories of Alsatian peasant life are known the whole world over. Emile Erckmann, born 20th May 1822, at Phalsbourg, studied law in Paris from 1842 to 1858; whilst Alexandre Chatrian, born 2d December 1826, in the village of Soldatenthal, from glass-blowing took to teaching in Phalsbourg, and afterwards got a railway clerkship. Their literary partnership dates from 1848; but for ten or eleven

years they had little success beyond getting some of their stories printed in various newspapers and journals. It was not till 1859 that *L'Illustré Docteur Mathéus* (1859) gave a certain éclat to the collective name of Eickmann-Chatrian. *Le Fou Yégoïf* (1862) is one of a series of novels which give graphic pictures of the invasion of 1813-14, to which series also belong *Histoire d'un Conscrit de 1813* (1864) and *Waterloo* (1865). *Le Joueur de Clarinette* (1863), a simple story of a village musician; *Les Amoureux de Catherine*, another tale of village life in the same volume; *L'Ami Fritz* (1864); *Madame Thérèse, ou les Volontaires de '92* (1863); *Le Blocus* (1867; Eng. trans. *Blockade of Phalsbourg*, 1870); *Histoire d'un Paysan* (1868); and *Contes Populaires*, most of which have been translated into English, count amongst the best they wrote. Three plays by them also achieved success—*Le Juif Polonais* (1869; well known as *The Belts*), the dramatic version of *L'Ami Fritz* (1876), and *Les Rantzau* (1882). See MASCAGNI. After the German annexation of Alsace-Lorraine (1871) a strong anti-German feeling appeared in their books—the best of these *L'Histoire d'un Plébiscite* (1872). They had quarrelled, when Chatrian died 4th September 1890. Erckmann died at Lunéville, 14th March 1899. Edmond About thus described their partnership: 'The two friends see one another very rarely. When they do meet, they elaborate together the scheme of a work. Then Erckmann writes it, Chatrian corrects it, and sometimes puts it in the fire.'

Erddmann, JOHANN EDUARD, German philosopher, was born in 1805 at Wolmar in Livonia, studied at Dorpat and Berlin, coming under the influence of Hegel, and became professor of Philosophy at Halle in 1839. He died 12th June 1892. His principal work was a *Grundriss der Geschichte der Philosophie* (3d ed. 1877), besides which he also wrote a work on Logic and Metaphysics, two books on Psychology, two collections of essays (one entitled *Ernstes Spiele*), and works on *Nature and Creation*, *Body and Soul*, *Belief and Science*, and *The State*.

Erebus, the name of one of the sons of Chaos, signifies darkness, and is used specially to denote the dark and gloomy cavern beneath the earth, through which the shades pass in going to Hades.

Erebus, MOUNT, an active volcano in Mac-Murdo Sound, off Antarctica (q.v.), rising 13,350 feet above the sea. It was discovered in 1841 by Ross, who named it after one of his vessels, and was ascended by Professor David with a party in 1908.

Erechtheus, or ERICHTHONIUS, an Attic hero, is said to have been the son of Hephaestus and Athlis, daughter of Cranaus, the son-in-law and successor of Cecrops. He was brought up by Athena, who placed him in a chest, which was intrusted to the three daughters of Cecrops. In defiance of orders they opened the chest, and discovering a child entwined with serpents, were seized with madness, and threw themselves down the most precipitous part of the Acropolis. Erechtheus instituted the Panathenaea, and in his honour was erected the Erechtheum, burnt by the Persians, and rebuilt as a noble Ionic temple. See SWINBURNE's great tragedy of *Erechtheus*.

Eregli (anc. *Heracleia Pontica*), the only port on the Black Sea coast between the Bosphorus and Sinope. See HERACLEIA. There is another Eregli on the Bagdad railway, 120 miles ESE. of Konia.

Eremacausis is a kind of slow Combustion (q.v.) with Fermentation (q.v.).

Eretria, a town on the SW. coast of Euboea, which, destroyed by the Persians in 490 B.C. and rebuilt by the Athenians, never afterwards

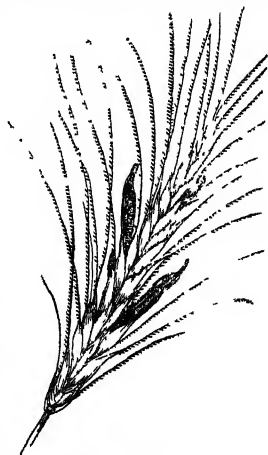

regained its former prosperity and importance. The modern town, Nea Pesara, is a small, unwholesome place, surrounded by swamps.

Erfurt, a city of Prussian Saxony, anciently capital of Thuringia, stands in a highly cultivated plain, on the Gera, 13 miles W. of Weimar by rail. Till 1873 it was strongly fortified. Its two citadels, the Petersberg and the Cyriaksburg, were formerly monasteries. Erfurt has several churches, chiefly Gothic, the cathedral and the church of St Severus being the finest. The cathedral, one of the most venerable Gothic buildings in Germany, possesses, besides a very rich portal, sculptures and bronze castings dating from the 13th to the 16th century, especially a Coronation of the Virgin, by Peter Vischer (1521). In the northern tower is the bell called *Maria Gloriosa*, cast in 1497, and weighing 13½ tons. The Regler Church contains an altarpiece by Wohlgemuth. The monastery of St Augustine, famous as the residence of Luther, whose cell was destroyed by fire in 1872, was converted in the year 1819 into an asylum for deserted children. From 1378 to 1816 Erfurt was the seat of a university, of which the academy of sciences and the library alone remain. The growing of flowers and vegetables, and an extensive trade in flower-seeds, are carried on. The principal manufactures are woollen, silk, cotton, and linen goods, lamps, machines, shoes, beer, malt, &c. Pop. (1871) 43,616; (1880) 53,254; (1900) 85,190; (1910) 111,461; (1919) 129,646.

Erfurt, originally called Erpesford or Erpesfurt, was made a bishopric in 741, and in 805 the capital of the Sorbs by Charlemagne. In the 15th century its woollen and linen manufactures raised it to the position of one of the foremost cities of Germany. All through, the town has had a stormy history, being either the bone of contention between the electors of Mainz and of Saxony, or the object of attack by foreign invaders. Since 1803 (except the period from 1806 to 1814) it has belonged to Prussia. At the Congress of Erfurt (September-October 1808) Napoleon met the Emperor of Russia and several of the minor sovereign princes of Germany.

Ergasteria, or Laurium, a mining-town in the Greek nomarchy of Attica, near Cape Colonna, with ancient lead and silver works, reopened in 1864; pop. 10,000.

Ergot, a diseased condition of the ovary of grasses and sedges, due to the presence of species of *Claviceps*, a *Pyrenomycete fungus* (see FUNGI), whose filamentous mycelium ramifies through the tissue of the ovary, which becomes deformed and enlarged. Multitudes of spores are formed and embedded in a sweet fluid ('honey-dew'), and are carried by insects to other plants. The mould now withers on the surface, but the deeper mycelium within the ovary becomes denser and harder, forming the so-called sclerotium, and lies dormant until the grain is sown in early spring, when it bears globular heads which contain depressions or perithecia, containing the ascospores, which again recommence the cycle. The medicinal 'ergot of rye' is that formed by *Claviceps purpurea*.

Ergot of Rye.

Producing rapid contraction of the uterus, it is often employed in midwifery; but its use in unskilled or unscrupulous hands is attended by the most serious risks. It has also been used in dysentery, epilepsy, whooping-cough, and as a styptic. Several powerful alkaloids, obscure in their mutual relations, are got from ergot. The continued eating of bread made of ergotised rye produces a specific disease called *Ergotism*. This is a terrible form of poisoning, in which not only convulsions appear, but often also gangrene of the extremities, resulting in mutilation or death, even recovery from less serious doses being slow and difficult. Many dreadful epidemics in rye-consuming countries (as in Lorraine and Burgundy in 1816), the causes of which were not understood, are now supposed to have been due to ergotism. See also **RAPHANIA**.

Eric, the name of several Danish and Swedish kings.—**ERIC VII.**, king of Denmark, born in 1382, the son of Duke Wratislaw of Pomerania, was selected as her successor by Queen Margaret of Denmark, and in 1412 mounted the throne of Denmark, Norway, and Sweden, united according to the treaty of Calmar. Cruel and cowardly in his character, he lost Sweden in 1437 through a revolt of the peasants of Dalecarlia, and in 1439 was deposed also in Denmark. He died in Rugenwald in 1459.—**ERIC VIII.**, the Saint, became king of Sweden in 1155, did much to extend Christianity in his dominions, and to improve the laws, and fell in battle with the Danes in 1160.—**ERIC XIV.**, the last of the name who reigned in Sweden, succeeded in 1560 to the throne of his father, the great Gustavus Vasa, and at once began to exhibit the folly that disgraced his reign. His flighty matrimonial schemes reached even Elizabeth of England and Mary of Scotland, until at length (1567) his roving fancy found rest in the love of a Swedish peasant-girl, who acquired an influence over him which was ascribed by the superstitious to witchcraft, since she alone was able to control him in the violent paroxysms of blind fury to which he was subject. His capricious cruelties and the disastrous wars that followed on his follies at length alienated the minds of his subjects, who threw off their allegiance in 1568, and solemnly elected his brother John to the throne. Nine years later the unhappy Eric ended his miserable life half voluntarily by a cup of poison. This crazy madman had a genuine love of letters, and solaced his captivity with music and the composition of psalms. His story has been worked into dramatic form by Swedish poets; in German by Kruse in his tragedy, *König Erich* (1871).

Ericaceæ, or **HEATHS**, a large, widely distributed order of sympetalous dicotyledons, chiefly small shrubs, frequently evergreen and social in growth, covering large areas, especially in mountainous regions and on tablelands. See **HEATH**, **RHODODENDRON**, **AZALEA**, **ANDROMEDA**, **ARBUTUS**, **CRANBERRY**, **KALMIA**, &c.

Ericht, **LOCH**, a lonely lake between Perth and Inverness shires, 1 mile from Dalwhinnie station, and 60 miles NW. of Perth. Lying 1153 feet above sea-level, it stretches 14½ miles south-south-westward, varies in width between ¼ and 1½ mile, is overhung by Ben Alder (3757 feet), abounds in salmo-ferox and trout, and sends a stream 6 miles to Loch Rannoch. The maximum depth is 512 feet.

Ericsson, **JOHN**, engineer, was born at Langbanshyttan, in the Swedish province of Vermland, 31st January 1802. After serving for some time as an officer of engineers in the Swedish army, he removed in 1826 to England, and continued to occupy himself with improvements chiefly on steam machinery and its applications. In 1829, for the

Liverpool and Manchester railway race, he built within six weeks (so it is said) the *Novelty*, a steam-engine which, had not the fan broken down at the last moment, might have proved a formidable competitor to Stephenson's *Rocket*. In 1836 he took out a patent for the screw-propeller (see **SHIP-BUILDING**). In 1839 he went to the United States, where he furnished designs for the warship *Princeton*, the first steamer that had her engines and boilers entirely below the water-line, and brought out his improved caloric engine (see **AIR-ENGINE**) and numerous other inventions. In 1861, during the civil war, he designed and finished in one hundred days the ironclad *Monitor* (see the article **NAVY**), and in 1862 built a number of similar vessels for the American navy. 'The *Destroyer*, a vessel with under-water guns, from which projectiles enclosing 300 lb. of gun-cotton were to be fired into an enemy below her armour-plating, was tried in 1881, but failed to satisfy the requirements of the navy board. In 1883 he erected a 'sun motor' in New York: his earlier experiments for developing power from the direct rays of the sun are described in his magnificent volume, *Contributions to the Centennial Exhibition* (1876). He died in New York, 8th March 1889. By his own wish he was buried in the place of his birth, a United States man-of-war conveying his body in 1890 to Langbanshyttan; and it was decided to erect his statue in Stockholm. His inventions covered nearly the whole field of mechanical engineering, and revolutionised both the navigation and the navies of the world. His great services to science were recognised by the governments of the United States, Sweden, Denmark, Spain, and Austria, as well as by many learned societies in America and Europe. See his *Life* by W. C. Church (1891).

Erid'anus. See **PO**.

Erie, one of the five great lakes which empty themselves by the St Lawrence, separates the province of Ontario, in Canada, on its left, from Michigan, Ohio, Pennsylvania, and New York on its right. It is the most southern of the five, receiving at its western extremity the waters of Lakes Superior, Michigan, and Huron by the river Detroit, and discharging them at its north-east by the Niagara into Lake Ontario. With a length of 240 miles, Erie has a breadth varying from 30 to nearly 60 miles, with an area of 9960 sq. m. It is 3½ feet below the Huron, and 326 and 573 respectively above the Ontario and the Atlantic. The shores are for the most part low and of a clayey nature. At its south-western extremity are several wooded and partly cultivated islands, the largest of which is about 14 miles in circumference. It is by far the shallowest of the five great lakes. Its mean depth is 100 feet, its maximum 210 feet; this comparative shallowness and the consequent liability to a heavy ground-swell, together with a lack of good harbours, and a frequency of severe storms, renders navigation peculiarly difficult and dangerous. The chief harbours on the United States shore, besides the natural harbour of Erie itself or Presque Isle, are those of Buffalo, Dunkirk, Cleveland, Sandusky, and Toledo; and on the north or Canadian shore, Ports Dover, Burwell, Colborne, and Stanley. Lake Erie receives no rivers of any consequence, except the Detroit and Maumee. Its commercial importance, however, has been largely increased by art. It is connected by one canal with the Hudson (see **CANAL**), and by more than one with the Ohio; while, on the Canadian side, it communicates with the Ontario by means of an important work, the ship-channel of the Welland Canal. Its navigation generally closes in the beginning of December, and the lake remains more or less frozen till March or April.

The commercial importance of this lake has been greatly enhanced within recent years by the establishment of numerous lines of railway connecting its ports with the interior. The amount of traffic on the lake and on these railways is enormous. Lake Erie was the scene of a naval engagement between the British and Americans, September 10, 1813, in which the latter were victorious.

Erie, the capital of Erie county, Pennsylvania, on Lake Erie, 88 miles SW. of Buffalo, and 95 NE. of Cleveland, is a port of entry, an important centre of trade, and connected by rail with New York, Philadelphia, Pittsburgh, and other cities. Its harbour, one of the largest and best on the lake, is formed by an island of 4 miles in length, which, under the appellation of Presque Isle (Fr., 'peninsula'), still preserves the memory of its having been once connected with the mainland. The belt of water thus sheltered is known as Presque Isle Bay, and forms a natural harbour for the city; it is now protected by a breakwater, is 3 to 4 miles long and 1 mile wide, and varies in depth from 9 to 25 feet. It has a number of attractive buildings, but its chief interest is commercial, there being a large lake commerce in which coal, oil, iron, and manufactured goods are exported. Its industries comprise oil-refineries, tanneries, iron-foundries, planing, paper, and flour mills, and manufactures of engines, boilers, farming implements, &c. Electrical supply works have been introduced. Natural gas supplies the city with domestic fuel. Pop. (1870) 19,646; (1890) 40,634; (1910) 66,525; (1920) 102,093.

Erigena, JOHANNES SCOTUS (earlier known as Scotigena, Jerugena, or Erugena), a famous philosopher of the 9th century, came, according to his friend Prudentius, from Ireland. He must have been born there between 800 and 815. His residence, from 847 or earlier, at the court of Charles the Bald, in France, where he is said to have been the head of the 'court school' (*schola palatina*), is the only part of his history that is certainly known. He came (851) to the help of Hincmar in the Predestination controversy with the doctrine, hitherto unknown in the West, that evil is simply that which has no existence, and that therefore damnation is not a positive punishment by God, but only consists in the consciousness of having failed to fulfil the divine purpose. The Council of Valence condemned this *pulvis Scotorum* ('Scots' porridge') as 'an invention of the devil.' The tradition is that, after the death of Charles the Bald (877), Erigena was forced to leave France under the suspicion of heresy, was called to England by Alfred the Great, and about 880, as abbot of Malmesbury, was stabbed to death with their pens by his scholars. Erigena translated only too literally, into Latin (860), the writings of the pseudo-Dionysius the Areopagite, and afterwards the Greek scholia of Maximus to the writings of Gregory Nazianzen. His chief work, *De Divisione Naturæ*, lib. v. (perhaps c. 865-870), was condemned by a provincial council at Sens, and by Pope Honorius III. (1225), who described the book as 'swarming with worms of heretical perversity.' It was published by Gale (Oxford, 1681), and was placed on the *Index librorum prohibitorum* by Gregory XIII. in 1685. In this work Erigena's aim was to reconcile authority with reason. His system is not so much Pantheism as Monism. God and the world are merged in the higher unity of 'Nature.' Nature—to Erigena the sum of all being and not-being (the necessary complement of being)—has a fourfold form of existence: (1) *Natura creans non creata*—i.e. God, as the uncreated Creator of all things; (2) *Natura creata creans*—i.e. the Word from God, by whom all things are made (the Son); (3) *Natura creata*

non creans—i.e. the world, creation, or nature in the narrower sense; (4) *Natura non creans et non creata*—i.e. God, as the final goal of all creation, to whom everything created returns in a universal Apocatastasis (q.v.). One of the last scholars in the West who could read Greek, Erigena shows strong leanings to the East. His thought comes, partly through pseudo-Dionysius, Maximus, Gregory of Nyssa, and Augustine, from the Neo-Platonists and Plato himself. His influence, slender in the Middle Ages, has been traced in Maimonides, Spinoza, Hegel, and the modern idealists. Mr Bett declares him 'the greatest thinker of his own day, and one of the greatest metaphysicians of all time.'

The works of Erigena (some spurious), edited by H. T. Floss, form vol. cxxii. (Paris, 1853) of the *Patrologia* of Migne. His Life has been written by Staudenmaier (1834) and Hermens (1868). See the monographs by Taillandier (1843), Christlieb (1860), Huber (1861), Hoffmann (1876), and Buchwald (1884); R. Lane Poole, *Illustrations of the History of Mediæval Thought*, and works by Gardner (1900), Rand (1906), H. Bett (1925).

Erigeron, a genus of composite weeds, allied to Aster. The British *E. acer*, sometimes called Fleabane, has been used as a source of potash, and was formerly in medicinal repute. *E. canadense* has become a common weed in Europe.

Erin (O. Ir. *Erinn*, dat. sing of *Eriu*), an ancient name for Ireland.

Erinna, a Greek poetess, the intimate friend of Sappho, born at Rhodes, or on the little island of Telos, to the west of Rhodes. The hypothesis of a second poetess of the same name, in the 4th century B.C., which is based on a statement of Eusebius, is generally rejected. Though she died at the early age of nineteen, Erinna acquired such celebrity by her epics, that her verses were compared with those of Homer. Of her principal poem only four lines are extant; and, of the three epigrams preserved in Schneidewin's *Delectus Poësis Græcæ Elegiacæ* (Göttingen, 1839), two at least are not genuine.

Erinyes. See EUMENIDES.

Eriobotrya. See LOQUAT.

Eriocaulaceæ, a small order of monocotyledons, allied to Restiaceæ, of grassy or rushy aspect, of marsh or aquatic habit, and unimportant properties. The 300 species are chiefly tropical; the North American *Eriocaulon septangulare* (Pipe-wort), however, occurs in muddy lake bottoms in West Ireland and the Hebrides.

Eriodendron (Wool-tree), a genus of Bombacaceæ (q.v.), East and West Indian trees with woolly seed. The wool (kapok) is used for stuffing pillows, &c. The seeds yield oil, and are edible. See SILK-COTTON.

Eriophorum. See COTTON-GRASS.

Eris, in Greek mythology, the sister of Ares, and personification of strife.

Erith, a town of Kent, on the right bank of the Thames, 15½ miles by rail E. of Charing Cross. A summer-resort for Londoners, and the headquarters of several yacht clubs, it has a number of fine villas, and a much-restored church, rich in basses; whilst in the Erith and Plumstead Marshes are large powder magazines. At Erith the *Grace de Dieu* was built in 1515. Pop. (1881) 9812; (1921) 31,568.

Eritrea, or ERYTHREA, an Italian colony (45,400 sq. m.) in Africa, between Abyssinia and the Red Sea, consists of a northern tableland, a continuation of that of Abyssinia, whose highest parts reach about 10,000 feet, and a narrow southern coastal plain diversified by volcanoes and other hills. The Dahlak Islands form part of the colony. The climate is very hot on the plains, warm temperate on the plateau, approaching to alpine on

the highest hills. The inhabitants (Arabs, Abyssinians, Somalis, and others) number over 400,000. They are partly pastoral nomads, with great herds of camels, oxen, sheep, and goats. Hides are exported. Pearls are got at Massawa and the Dahlak Islands, gold near Asmara. Cereals are raised in the higher regions by help of irrigation; and there is a trade in palm-nuts. There is a railway (75 miles) from the port of Massawa to Asmara, the capital, and one (65 miles) from Asmara to Cheren.

Erivan (Persian *Rewân*), a town of Armenia, formerly capital of a Russian government, lies on the elevated plain to the north of Ararat, 3432 feet above the level of the sea. It has Russian and Armenian churches, and mosques, besides a citadel and a large bazaar. Close by resides the head of the Armenian church (see ECHMIADZIN). The town dates probably from the 7th century A.D.; in later years it was held alternately by Persians and Turks. Population, 90,000. In 1827 it was stormed by the Russian general, Paskevich, who received the surname of Erivanski; and by the treaty of peace concluded at Turkmanshai, 22d February 1828, both town and province were given up by Persia to Russia. The province (area of 10,000 sq. m., pop. 1,000,000), along with Kars, proclaimed itself a republic in 1918, as a nucleus of an Armenian republic. See ARMENIA.

Erlangen, a town of Bavaria, on the Regnitz, 12 miles N. of Nurnberg. As old as the 10th century, it owes its prosperity to the settlement of French Huguenots after the revocation of the Edict of Nantes (1685), and to its university (1743), which is celebrated as a school of Protestant theology. A statue of its founder, the Margrave Frederick of Brandenburg-Baireuth, was erected in the market-place in 1843. Brewing is the staple industry; and besides its extensive stocking and glove manufactories, which provide the greater part of Germany with their goods, Erlangen has great mirror and tobacco factories. Burnt in 1449 and 1632, Erlangen came to Bavaria in 1809. Pop. 24,000, of whom four-fifths are Protestants.

Erlau (Mag. *Eger*), a city of Hungary, on the river Eilau, 89 miles N.E. of Budapest by rail. The archiepiscopal cathedral, built since 1837, is a domed cruciform building, 328 feet long. The lyceum (1761-99) has a valuable library and an observatory; and there is a richly-endowed hospital (1830). Two warm baths are much resorted to. The Erlau wine is the best red wine of Hungary. The population is over 28,000. Dating from 1010, Erlau suffered much at the hands of the Turks, who held it from 1596 till 1687.

Erlkönig, a German mistranslation ('alder king') of the Danish *Ellerkonge* ('king of the elves'). It was first used by Heider instead of *Elfenkönig*; and Goethe followed in his famous ballad (consummately set to music by Schubert), in which a human child summoned by the Erlking dies in his father's arms.

Ermeland, or ERMLAND, one of the eleven districts of the old province of Prussia, extending inland from the Frisches Haff, was created in 1250 one of the four bishoprics of the country of the Teutonic Knights. In 1354 the Bishop of Ermeland, who hitherto had been subject to the Archbishop of Riga, was made directly dependent upon the pope, and elevated to the position of a prince of the empire. When, in 1466, West Prussia was transferred to Poland, the Bishop of Ermeland became a member of the Polish senate, with sundry privileges. Since 1772 Ermeland and its bishop have again been Prussian. The name is still borne by a portion of the Prussian district of Königsberg, with sandy soil, but well wooded, in which a large quantity of flax is grown.

Ermenonville, a village in the French department of Oise, 18 miles N.N.E. of Paris. It was the death-place of Rousseau (q.v.).

Ermine, or STOAT (*Putorius ermineus*), a well-known carnivore in the Polecat and Mink section of the weasel or marten family (Mustelidæ). The lithe and slender body has a length of about 11 inches in the male, 9 in the female, and to that must be added a length of tail of about 6½ and rather less than 5 inches respectively. The colour of the stoat is ruddy brown in summer, yellowish beneath; but in winter, in the more northern

Ermine (*Putorius ermineus*): Summer and Winter Fur.

parts of its distribution, the ermine changes its fur into a beautiful white, sometimes with a tinge of lemon-yellow near the tail. There is a hereditary tendency to this seasonal change, to which the lowered temperature supplies the necessary stimulus. In milder regions the colour of the summer coat may persist through the year. The change to white, all but the black tip of the tail, is mainly due to a new growth of white hairs, but individual brown hairs may also become white. The protective value of the white fur in snowy regions is obvious. Like related species, the ermine is a very lithe, restless, brave, and blood-thirsty animal; it moves rapidly, and can both climb and swim well; it is terrestrial in its general habit, and finds a home among rocks and stones, in walls and the like. It sucks the blood of small mammals and birds, and, while valuable in destroying rats and mice, is sometimes a troublesome poacher on the poultry-yard. It is a singularly playful animal, and sometimes gambols in an extraordinary way in the presence of rabbits. It sometimes migrates in determined bands. It breeds at the end of the winter season.

The ermine occurs in Britain, especially in the north, is generally distributed in the northern parts of Europe, Asia, and America, but is common as far south as the Pyrenees and the Italian Alps. It is represented in Ireland by a smaller species (*P. hibernicus*). The white fur has long been used for trimming or lining the robes of dignitaries. The skins are usually imported from Norway, Lapland, Siberia, and the Hudson Bay regions. The yellow and black tails are inserted to contrast with the white fur. Ermine is the fur of most frequent use in Heraldry (q.v.). See FERRET, MARTEN, POLECAT, WEASEL.

Erne, a river and lake of Ireland. The river rises in Lough Gowna, on the borders of Longford and Cavan counties, flows 72 miles north-west through Loughs Oughter and Erne, and then through Donegal county into Donegal Bay. Lough Erne, one of the finest lochs in the kingdom, extending for 40 miles through Fermanagh county,

consists of two lakes, the Upper and Lower, joined by a network of channels 10 miles long. Both divisions are studded with green hilly islands, and contain abundance of salmon, trout, and other fish.

Erne (*Haliaeetus albicollis*), or White-tailed Sea-eagle, is one of the 'bare-legged' eagles, widely distributed in north Europe and Asia, and migrating in winter to North Africa, the Canary Islands, China, and Japan. Its breeding-places in Britain

Common Erne (*Haliaeetus albicollis*).

are now restricted to a few remote spots in the north and west; and it is a very rare bird compared with the Golden Eagle (*Aquila chrysaetos*), from which it may be distinguished by its unfeathered lower metatarsal region, its longer bill, and its white tail. In Britain the eyrie is now on a sea-cliff, but elsewhere, as previously in Britain, trees and other sites may be used. The diet is heterogeneously carnivorous; the cry is a shrill yelp. The general colour is brown, but the tail is white, and there is much white about the head and neck of old birds.

Another notable species is the White-headed or Bald Eagle (*H. leucocephalus*), the emblem of the United States. This erne is common in North America, both by the coasts and by inland lakes, from the north to California and Mexico. The general colour is again brown, but the head and neck of the adults are milky-white, and the same is true of the rounded tail. The size is slightly less than that of the British species. It feeds like other eagles, but is very fond of fish, which it gets for itself by wading, or obtains by theft from other birds. See EAGLE.

Ernest, the name of several German princes, for whom see HANOVER, SAXONY, SAXE-COBURG, ALTENBURG.

Ernesti, JOHANN AUGUST, a celebrated classical and biblical critic, was born at Tennstädt, in Thuringia, 4th August 1707. He studied (from 1726) at Wittenberg and Leipzig, and, devoting himself to classical studies, became rector of the Thomas School at Leipzig in 1734, a post which he held till 1759, along with first a chair of Humanity (from 1742), and then that of Rhetoric (from 1756) in the university. Becoming professor of Theology in 1759, he resigned the chair of Rhetoric in 1770, and died 11th September 1781. He prepared editions of Homer, Callimachus, Polybius, Suetonius, and Tacitus, and of Xenophon's *Memorabilia* and Aristophanes' *Clouds*, and an excellent edition of Cicero (3d ed. 5 vols. 1776-77), to which he added a valu-

able *Clavis Ciceroniana*, often re-edited. He was the founder of a true exegesis of Scripture by the laws of grammar and history, independent of dogmatic prepossessions. Of his *Institutio Interpretis Novi Testamenti* (1761) there are translations by Moses Stuart (1824) and Terrot (1833). His *Anti-Muratori* (1755) is a polemic against Roman Catholicism. His Latin speeches (published as *Opuscula Oratoria*) gained him the name of the 'German Cicero.'

Ernulphus, or ARNULF (1040-1124), a French Benedictine, appointed prior of Canterbury by Anselm, was subsequently abbot of Peterborough (1107) and bishop of Rochester (1114). He was equally remarkable for skill in canon law and personal saintliness; and compiled a great collection of documents about his own church, laws, papal decrees, &c., which from the old name of the see (*Hrofe-ceaster*) was known as the *Textus Roffensis* and it is to an extract from this that he owes the invidious distinction given him in *Tristram Shandy*. Sterne makes the pious bishop the supreme authority on cursing on the strength of the excerpt called *The Pope's Dreadful Curse: being the Form of Excommunication of the Church of Rome: taken out of the leger-book of the Church of Rochester, now in the custody of the Dean and Chapter there: writ by Ernulphus the bishop* (1681, in the *Haileian Miscellany*, vol. vi.).

Eros. See CUPID.

Erosion. See COLORADO, DENUDATION, GEOLOGY, MOUNTAINS, RIVERS.

Erostratus, or HEROSTRATUS. See EPHEBUS.

Erotic Poetry (Gr. *erōs*, 'love'), poetry in which love is the main subject.

Erotomania, a term used for morbid and extravagant love-passion either melancholic or maniacal (see INSANITY). In the latter case it is closely akin to the still more aggravated satyriasis (in men) and nymphomania (in women).

Erpenius (Thomas van Erpen), Orientalist, was born at Gorkum, in Holland, 7th September 1584, studied at Leyden, and at Paris learned Arabic from an Egyptian. In 1613 he became professor of Oriental Languages at Leyden, where he erected an Arabic press in his own house. As oriental interpreter to the government, he read and wrote replies to all official documents coming from the East. He died of the plague, 13th November 1624. Arabic studies owe much to his labours. In spite of his poverty of materials, his famous grammar (*Grammatica Arabica*, Leyden, 1613) enjoyed undisputed supremacy for two hundred years; his *Rudimenta* (1620, often re-edited) had an even longer vogue. He also edited Lokman (q.v.); *Proverbiorum Arabicorum Centuriae Duæ* (1614); and El-Mekim's *Historia Saracenicæ* (1625).

Errata, the list of errors with their corrections placed at the beginning or end of a book. From greater carelessness in correcting the sheets in passing through the press, errors in sense or typography are now much more rare than formerly; but few books are without some typographical errors. See PROOFS (CORRECTION OF).

Erratics. See BOULDERS, GLACIAL PERIOD.

Erromango, one of the New Hebrides (q.v.), on which the missionary John Williams (q.v.) was murdered and eaten by the savage natives.

Error, in English law, is any mistake in fact, in law, or in the form of process, requiring to be set right by the court before which an action is tried, or by a court of review. If the error was in fact, the case, under the old system, was heard before the court in which the action was originally tried; if the error was in law, proceedings had to be taken before the Court of Exchequer

Chamber (see EXCHEQUER). Where a party disputed the ruling of the judge, the form was by Bill of Exceptions (q.v.). According to the former practice, it was necessary, in order to obtain a review on the ground of error, that an original writ, called a Writ of Error, should be issued. The writ, if the error was in fact, was styled *coram nobis*, where the case was in the King's Bench, the sovereign being presumed to preside in that court; if in the other courts, the writ was *coram vobis*. Writ of error in civil cases in the High Court is abolished by the Judicature Acts, and so is Bill of Exceptions. Since 1875 all appeals are to the Court of Appeal by way of rehearing, and are brought by notice of motion in a summary way, and no petition or other formal proceeding other than such notice of motion is now necessary. The appellant may by the notice of motion appeal from the whole or part of any judgment, and this does not usually stay proceedings. Nearly all the judgments of the Divisional Courts of the High Court are subject to appeal to the Court of Appeal and thence to the House of Lords. The jurisdiction was transferred to the High Court of Justice in 1875, which used formerly to be vested in the Common Pleas at Lancaster and at Durham, and which used to be by writ of error to the Queen's Bench. Writs of error used formerly also to be brought on judgments of inferior courts. But since the establishment of County Courts and the changes introduced by the Judicature Acts, the analogous proceeding is an appeal by way of a case stated for opinion of the High Court, and sometimes by motion in a summary way. In criminal cases, error did not lie for formal defects in the indictment; these had to be objected to before the jury was sworn, and might then be amended. A writ of error lay for a defect in substance appearing in the indictment, as in the case of *Bradlaugh v. the Queen*, where an indictment for publishing an obscene book was held defective because it mentioned the book by title only, instead of setting out the passages alleged to be obscene. A prisoner had therefore three opportunities of taking legal objections; he might demur to the indictment, or move in arrest of judgment, or sue out a writ of error. This was abolished by the Criminal Appeal Act of 1907.

In the United States, the procedure of the State Courts follows the analogy of the English common law; in the Federal Courts the term error is also known; for further details reference may be made to the Acts of Congress and of the several State legislatures.

Errors. In all observations errors must be made. The best instruments have imperfections; and no man, however equable his temperament, can always rely on his making a proper use of his senses. As in astronomy numerical correctness in the results of instrumental measurements is of the first consequence, it is the constant care of the observer to detect and make allowance for errors. The three principal sources from which they may arise are—(1) External or incidental causes, such as fluctuations of weather, which disturb the amount of refraction; changes of temperature, affecting the form and position of instruments, &c.; (2) Errors of observation, being such as arise from inexactness, defective vision, slowness in seizing the exact instant of an occurrence, atmospheric indistinctness, &c.; and such errors as arise from slips in clamping and momentary derangements of the instrument; (3) Instrumental defects, owing to errors in workmanship, and such as arise from the instrument not being properly placed—called errors of adjustment. The first two classes of errors, so far as they cannot be reduced to known laws, vitiate the results of observations to their full extent; but being accidental, they necessarily sometimes

diminish and sometimes increase them. Hence, by taking numerous observations under varied circumstances, and by taking the *mean* or *average* of the results obtained, these errors may be made to destroy one another to a great extent, and so far may be subdued. With regard to the third class, it is the peculiarity of astronomical observations to be the ultimate means of detection of all defects of workmanship and adjustment in instruments, which by their minuteness elude every other mode of detection. It may be mentioned, however, that the method of subduing errors of the first two classes by the law of average is not applicable in all cases. In certain cases recourse must be had to the Method of Least Squares. See SQUARES, and PROBABILITY.

Ersch, JOHANN SAMUEL, a great German bibliographer, was born at Grossglogau, in Lower Silesia, 23d June 1766; studied theology, next history, at Halle; and after some years of journalism at Jena and Hamburg, became in 1800 librarian to the university of Jena. Three years later, he was called to Halle as professor of Geography and Statistics; and in 1808 was also appointed principal librarian. He died at Halle, 16th January 1818. Ersch was long engaged in miscellaneous bibliographical work for other scholars; but in 1818, along with Gruber, commenced the publication at Leipzig of the famous yet unfinished *Allgemeine Encyklopädie der Wissenschaften und Künste* (see ENCYCLOPEDIA). By his *Handbuch der Deutschen Literatur seit der Mitte des 18 Jahrh.* (4 vols. 1812-14) he first established modern German bibliography in the technical sense of the word.

Erse (a corruption of *Irish*), a name given less frequently now than formerly to the Gaelic (q.v.) of both Ireland and the Scottish Highlands.

Erskine, EBENEZER, the founder of the Secession Church in Scotland, was the son of the minister of Chirnside, in Berwickshire, a scion of the noble family of Mar (q.v.), and was born June 22, 1680. He studied at Edinburgh, and, after acting as tutor and chaplain in the family of the Earl of Rothes, was licensed by the presbytery of Kirkcaldy in 1703. His abilities soon brought him into notice, and in the same year he was appointed minister of Portmoak, in Kinross-shire; and here the unction and piety which marked his discourses became exceedingly attractive to the people accustomed to the chilling 'legalism' which then predominated in the Scottish pulpit. He took a deep interest in all public questions, both in church and state, and consequently, on the rise of the Marrow Controversy (q.v.), he was one of the most prominent on the evangelical side. After having discharged the pastoral office in Portmoak for about twenty-eight years, Erskine was in 1731 translated to Stirling. Just then the patronage dispute arose, and Erskine distinguished himself by his powerful advocacy of the right of the people to choose their own pastors. Declining to receive censure for certain statements made by him on this question in a Synod sermon which had given offence to the prevailing party in the church, he, with other three ministers who adhered to him, was in 1733 suspended and then deposed from the ministry. The sentence, however, was recalled in the following year, and Erskine was invited to return. But this he declined to do unless the evils he contended against were removed. The invitation remained open until 1740, when, finding further effort hopeless, the Assembly again deposed Erskine, and ejected him from his church. On the first deposition, Erskine and those adhering to him stated a formal secession from the judicatories of the Established Church, and at Gairney Bridge, near Kinross, erected themselves into the 'Associate Presbytery.' This was

the origin of the Secession Church (see UNITED PRESBYTERIANS). In the division in 1747 of the Seceders into Burghers and Anti-burghers, Erskine took the leading part on the side of the Burghers. He was twice married, and had fifteen children. He died 2d June 1754. His *Sermons and Discourses* fill 4 vols. (Glasgow, 1762). See Lives by D. Fraser (1831) and Harper (1849); and *The Erskines: Ebenezer and Ralph*, by John Ker, D.D., and J. L. Watson (Edin. 1882).

Erskine, HENRY, second son of the tenth Earl of Buchan, was born in Edinburgh, 1st November 1746, and was educated at the universities of St Andrews, Glasgow, and Edinburgh. He joined the Scottish bar in 1768. His rise was immediate, and commenced, like that of his rival Henry Dundas, from his appearances in the debates of the General Assembly. Under the short-lived coalition ministry of Fox and North, he became Lord Advocate (1783), an office to which he was again appointed in 1806. In 1785 he was elected Dean of the Faculty of Advocates, but in 1796 was deposed in favour of Robert Dundas of Arniston. This mark of professional censure was intended by the Faculty to stigmatise Erskine's conduct in attending a public meeting and supporting a resolution protesting against the 'Seditious Writings Bill' proposed by the government. Lord Cockburn justly says, 'It was the Faculty of Advocates alone that suffered.' Erskine was elected member for the Haddington burghs in March 1806, and in the following November for the Dumfries burghs. He died at Amondell, his seat near Midcalder, 8th October 1817. During his second tenure of the office of Lord Advocate, Erskine practically carried into effect some of the legal reforms for which a pamphlet, published in London in 1807, and attributed to him on good authority, pleaded forcibly—viz. the introduction of jury trial in civil cases, and the abolition of the rule by which the fifteen judges of the Court of Session sat together. He was the author of several metrical translations from the classics, and other poems, of which the best known is *The Emigrant* (1773), inspired by the depopulation of the Highlands. Erskine's forensic style was the delight of his contemporaries, and the recorded fragments of his speeches justify his high reputation as an orator and a wit, and warrant the conclusion that, had Henry Erskine, in his own witty language, 'played at the guinea tables' in London, instead of 'at the shilling tables' in Edinburgh, he would have been no unworthy rival to his distinguished brother, Lord Erskine. See Colonel Alexander Fergusson's *Henry Erskine* (1882).

Erskine, JOHN, of Dun, Scottish Reformer, was born in 1509. All through the reign of Mary Queen of Scots, and through part of that of her son James, Erskine took an active share in public affairs, lending steadfast support to the reformed preachers, especially to Wishart and Knox, whilst at the same time his moderate and conciliatory temper not only secured him against the enmity of the leaders of the Catholic party, but gave him considerable personal influence in the country. He was frequently chosen to negotiate between the Reformers and the representatives of the sovereign, and to mediate between the different sections amongst the Reformers themselves. From 1560 down to about 1589, two years before his death, he held the office of superintendent for the reformed district of Angus and Mearns. Although a layman, he was elected on at least five separate occasions moderator of the General Assembly, and was one of the compilers of the *Second Book of Discipline* (1578).

Erskine, JOHN, Scottish jurist, was born in 1695, the son of the Hon. Colonel Erskine of

Carnock, Fife. He was called to the bar in 1719, but did better as a lecturer than a practitioner, having in 1737 been appointed to the chair of Scots Law in Edinburgh University. He resigned it in 1763, and died on 1st March 1768 at Cardross, near the Lake of Menteith, which estate he had purchased in 1746. His two works are still held in deserved repute—*Principles of the Law of Scotland* (1754; 17th ed. 1886), and the more important *Institutes of the Law of Scotland* (1773; 9th ed. 1871). As a legal writer, indeed, he is second only to Stair, the sterling merits both of the *Principles* and of the *Institutes* being their plainness and sound common sense.

Erskine, JOHN, D.D., son of the preceding, was born June 2, 1721. He studied at the university of Edinburgh, and, licensed to preach in 1743, was appointed minister successively of Kirkintilloch (1744), Culross (1753), New Greyfriars Church, Edinburgh (1758), and the collegiate charge of Old Greyfriars (1767), where he had for his colleague Dr Robertson. In 1766 the university of Glasgow conferred on him the honorary degree of D.D. In the General Assembly he was for many years the leader of the popular or evangelical party; and between him and Principal Robertson, the leader of the Moderate party, there was a courteous and honourable friendship. Erskine's twenty-five publications are of a high order of ability. They consist of essays, letters, sermons, dissertations, and pamphlets, &c., mainly of a religious character, even when dealing with the political American controversy, on which he wrote largely. He also edited a number of British editions of works of American divines. He died 19th January 1803. Sir Walter Scott, in *Guy Mannering*, describes his powers as a preacher. See Life by Sir H. Moncrieff Wellwood (1818).

Erskine, RALPH, brother of Ebenezer, was born at Monilaws, in Northumberland, March 18, 1685, and, after studying at Edinburgh, was ordained to the parish church of Dunfermline in 1711. Like his brother, he took part on the evangelical side in the Marrow Controversy (q.v.); and, after the formation of the Associate Presbytery, he withdrew from the communion of the Established Church, and joined the former in 1737. In the controversy concerning the burgess oath he also took part with the Burghers, and wrote several pamphlets in defence of their position. He was, however, less a controversial than a practical writer. Being a very popular preacher while he lived, his sermons were greatly prized after his death, and many of them were translated into Dutch and widely circulated in Holland. His *Gospel Sonnets and Scripture Songs* are well known. He died November 6, 1752. See the Life by James Fisher, prefixed to his *Practical Works* (2 vols. 1764).

Erskine, THOMAS, LORD ERSKINE, the youngest son of Henry David, tenth Earl of Buchan, was born in Edinburgh, 21st January 1750, and was educated at St Andrews. In 1764, much against his will, he was sent to sea in the *Tartar* man-of-war, under Sir David Lindsay. After cruising about for four years in the West Indies and on the coast of America, he obtained an ensign's commission in the 1st Royals, at a price which absorbed his whole patrimony (1768), and was for some time stationed at Minorca, where he employed his leisure time in a minute and devoted study of Shakespeare, Milton, Dryden, Pope, and other masters of English literature. On his return to London in 1772, Erskine mingled freely with the best social and literary circles, and acquired a distaste for military life, which an accidental visit to an assize court, and an interview with Lord Mansfield, turned into a determination to

prosecute the study of law. He was admitted to Lincoln's Inn, 26th April 1775; and in 1776 entered Trinity College, Cambridge, where he took an honorary M.A. in 1778, just before being called to the bar. His professional career was one of immediate and unprecedented success. Accident threw in his way a retainer in the case of Captain Baillie, lieutenant-governor of Greenwich Hospital, who was threatened with a criminal prosecution for libel, at the instance of Lord Sandwich, the First Lord of the Admiralty. Erskine's advocacy secured the discharge of the rule for leave to file an information (24th November 1778), and as he left Westminster Hall from the scene of this signal victory the attorneys flocked round him with their retainers to the number, as he afterwards used to tell, of sixty-five. The next year saw an equally successful defence of Admiral Lord Keppel against charges of professional misconduct and incompetence. In 1781 Erskine secured the acquittal of Lord George Gordon, indicted for high-treason in connection with his conduct during the notorious riots, and on this occasion delivered his first assault upon the doctrine of *constructive* treason, by which it was sought to make persons who aimed at effecting a change in the sovereign's constitutional character and position guilty of the capital offence of 'compassing the king's death.' In 1783 Erskine was appointed a King's Counsel on the special recommendation of Lord Mansfield, and at the same time was returned as member of parliament for Portsmouth. The high expectations of his friends were rudely disappointed by his first political appearance in the House of Commons, and, although he subsequently made effective and eloquent speeches, he never became a parliamentary orator. 'I'll tell you how it happens, Erskine,' said Sheridan, 'you're afraid of Pitt; and that is the flabby part of your character.' Erskine's sympathy with the French Revolution, aroused by a visit to Paris in 1791, led him to join the 'Society of the Friends of the People'—whose object was to bring about parliamentary reform—and to undertake the defence in the principal political prosecutions of 1793–94. His courageous acceptance of a retainer from Tom Paine resulted in his removal from the office of Attorney-general to the Prince of Wales, to which he had been appointed in 1786. But his speeches for this unpopular defendant, and for Frost (1793), Hardy (1794), and Horne Tooke (1794), are among the finest specimens of forensic skill, and, in the language of Hardy, 'will live for ever.' Erskine's defence of Hadfield (April 26, 1800), indicted for shooting at George III. in Drury Lane Theatre, was a powerful and logical analysis of a theory of criminal responsibility in mental disease, which had hitherto done bloody duty in English courts of law. In 1802 Erskine was appointed Chancellor to the Prince of Wales, an office which had lain dormant since the time of James I., but was now revived in his favour. In 1806 he was raised to the peerage and the woolsack, but soon retired into private life. He died at Amondell, Linlithgowshire, 17th November 1823.

Erskine had married first, in 1770, Frances, daughter of Daniel Moore, M.P. for Marlow; and secondly, at Gretna Green, when he must have been about seventy, a Miss Mary Buck. He published a pamphlet on the abuses of the army in 1772; a view of the causes and consequences of the war with France in 1797; a political romance, *Armata*; a pamphlet in favour of the Greeks; and some poems.

Erskine's decisions as Lord Chancellor were styled by his contemporaries the 'Apocrypha,' and have added nothing to his permanent fame. His

reputation is purely forensic, and in this respect is unrivalled in the history of the English bar. The charm of voice and presence and gesture may have contributed something to his unique influence over judges and jurymen; but the careful student will not fail to note in his speeches the enduring qualities of genuine sentiment, profound acquaintance with life and character, singular fertility in illustration, and powers of exposition and reasoning to which the history of advocacy hardly offers a parallel. See Campbell's *Lives of the Chancellors*, vol. viii.; Fergusson's *Henry Erskine* (1882); and Duméril's *Lord Erskine, a Study* (Paris, 1883).

Erskine, THOMAS, of Linlathen, was born in 1788, and educated at Edinburgh High School, at Durham, and at the university of Edinburgh. He was admitted advocate in 1810, but ceased to practise after his elder brother's death gave him the family estate of Linlathen, near Dundee, and devoted himself for the remainder of his uneventful life to his favourite theological studies. He died 20th March 1870. Erskine was brought up an Episcopalian, but in later life was at least nominally a member of the Church of Scotland. His theological opinions and religious sympathies hardly fell within the lines of the usual creed definitions, while a belief in the ultimate universal salvation of mankind and the worthlessness of miracles as evidence for inspiration were in his day scarcely consistent with formal citizenship within any church. He published several religious works. See his *Letters* (ed. W. Hanna, 1877–78), and his *Life* by H. F. Henderson (1900).

Erubescite, a copper ore consisting of sulphoferite of copper (Cu_2FeS_3), occurs crystallised in cubes, often twinned, or massive. It has a bronzy colour with a bluish tarnish.

Eruptive Rocks. See IGNEOUS ROCKS.

Ervine, ST JOHN GREER, Irish dramatist and novelist, was born in Belfast, 28th December 1883. Foisaking business in 1913 for literature, in which he had earlier won successes, he became in 1915 manager of the Abbey Theatre, Dublin. His plays, as *Jane Clegg* (1911), *John Ferguson* (1914), *The Ship*, &c., are mostly tragedies; his novels, as *Changung Winds* (1917) and *The Foolish Lovers* (1920), are much lighter in tone.

Eryngo (*Eryngium*), a genus of Umbelliferae, but of curiously thistle-like aspect, since the sessile flowers of the umbel form what is practically a capitulum. The large, spiny leaves recall those of holly, but have glaucous bloom, which in some species gives the foliage an opalescent blue colour. These especially are cultivated in flower-gardens, but the young leaves of *E. maritimum* (Sea-holly) are occasionally eaten as a salad; the Mediterranean species were also valued by the ancients. Many Elizabethan writers mention the use of the candied root. An American species is also used in domestic medicine.

Sea-holly (*Eryngium maritimum*).

Erysimum, a genus of Cruciferae allied to Hedge-mustard (*Sisymbrium*) and Dame's Violet (*Hesperis*). The seeds of *E. cheiranthoides* were formerly employed as an anthelmintic, hence the name of Worm-seed. It is also called Treacle Mustard, because an ingredient in the famous *Venice Treacle*. The seeds of *E. perfoliatum* are used as a source of oil in Japan.

Erysipelas (Gr., 'red skin'), an inflammatory and febrile disease of the skin, attended by diffused redness, pain, and swelling of the part affected, and in the end by either desquamation or vesication of the cuticle, or scarf-skin, in the milder forms, and by supuration of the deeper parts in the severer varieties of the disease (*phlegmonous erysipelas*). It is characterised by a marked tendency to spread over the skin from the place where it arises. Erysipelas affects, in a large proportion of instances, the face and head; it is apt to be attended with severe fever, and often with great disorder of the nervous system, arising in some instances from inflammation of the membranes of the brain. In other parts of the body, severe or phlegmonous erysipelas is apt to be succeeded by protracted and exhausting suppurations, and sometimes by diseases of the bones, or inflammations of the internal organs. Erysipelas in its severer forms usually commences in a wound or sore, and is extremely apt to be communicated to any one with a breach in the continuity of the skin who comes in contact with a case of the disease. Epidemic outbreaks of erysipelas used therefore to be common and disastrous in surgical and lying-in hospitals; but since the general introduction of antiseptic treatment they have almost disappeared. Erysipelas is very apt to recur in a person who has been attacked once or oftener; and this is especially true of the form which affects the face. It is due to the presence of a streptococcus in the affected tissues. The bowels should be well cleared out in most cases, and large amounts of fluid given to drink. For local application, if the skin be unbroken, ichthyol in glycerine, tincture of iodine, or other astringent, and antiseptic applications are used; when sloughing is in progress, strong antiseptic dressings are employed. In some cases iron is used as a specific remedy in the form of large doses of steel drops. It is of course important that no one liable to the disease should be exposed to the infection. St Antony's Fire (see ANTONY) and Rose are common names for erysipelas.

Erysiphe. See OIDIUM.

Erythema (Gr. *erythmaō*, 'I redden'), a name applied to certain skin diseases, but scarcely used by any two writers on the subject in exactly the same sense. It is used, generally speaking, of eruptions where there is circumscribed or diffuse redness, without any break in the skin surface, with or without elevation of the affected part. The chief forms described under the name are rashes like a persistent blush occurring in the course of some fevers, in consequence of drugs, or without ascertainable cause, but usually of short duration: *E. multiforme*, where the eruption is raised, and generally in the form of papules, rings, or irregular lines; *E. nodosum*, consisting of dark-red, painful swellings, usually on the front of the leg, and believed to be connected with various rheumatic manifestations; and cases closely resembling erysipelas, except that the symptoms, both local and constitutional, are very much less severe.

Erythraea. See CENTAURY, ERITREA.

Erythronium, a genus of Liliaceae. *E. dens canis*, the Dog-tooth Violet, so called because of the resemblance of its little white bulbs to dogs' teeth, is a well-known ornament of English flower-borders in spring. It is a native of southern Europe

and Siberia, where it is used as a source of food, and also medicinally.

Erythrophloeum, a genus of leguminous trees (sub-order Mimosae). The red juice of the bark of *E. guineense* is used in ordeals and for arrow-poisoning in Africa. See ORDEAL.

Erythroxylaceae, a small order of dicotyledonous trees or shrubs, chiefly South American, allied to Linaceae. *Erythroxylon suberosum* is a red dye-wood of Brazil. *E. hypericifolium* yields the *Bois d'huile* (Oil-wood) of Mauritius. For *E. coca*, see COCA.

Eryx, the ancient name of a mountain in the NW. of Sicily, near Drepanum (mod. Trapani), with a famous temple of Aphrodite *Erycina*.

Erzberg. See EISENERZ.

Erzberger, MATTHIAS, German politician, born at Bittenhausen, Württemberg, in 1875, became leader of the Centre in the Reichstag. In the Great War he was at first a war-aims propagandist, but came to be regarded as a defeatist. He headed the armistice delegation, and was finance minister in 1919-20. He was assassinated 26th August 1921. See his *Erlebnisse im Weltkrieg* (1920).

Erzerûm, an important town in Turkish Armenia, not far from the Kara-Su, stands on a high but tolerably well cultivated plain, 6200 feet above the level of the sea, surrounded by mountains. The climate is cold in winter, hot and dry in summer. The population is fluctuating, but estimated at about 40,000, mostly Turks, with some Armenians and Persians. The copper and iron wares of Erzerûm have acquired a wide celebrity. Situated at the junction of the important highways leading from Trebizond, Transcaucasia, Persia, Kurdistan, Mesopotamia, and Anatolia, Erzerûm forms an entrepôt of commerce between Europe on the one hand and the interior of Asia, and particularly Persia, on the other. The streets, the houses of which are built chiefly of volcanic stone cemented with mud, are narrow, crooked, and filthy; and ruins of fortifications and of buildings formerly magnificent everywhere meet the eye. The town consists of the fortress, strictly so called, and four suburbs. The fortress, which is inclosed by a high wall, has, on the west, a citadel (El-Kal'a), containing many curious monuments. There are numerous mosques in the town, that of *Ulu Jami* the chief; many churches, both Armenian and Roman Catholic; and various large bazaars and caravanserais. A medreseh, said to have been first erected in the 10th century, but with all its present architectural features of the 14th, is the most beautiful building, an ornamented doorway and two graceful minarets, known as the *Chifte Minarets*, being its outstanding features. Erzerûm imports shawls, silk goods, cotton, tobacco, rice, indigo, &c., and exports corn, sheep and cattle, horses, mules, and gall-nuts. The principal trades carried on are tanning, dyeing of morocco leather, and blacksmiths' and coppelsmiths' work. But since the Transcaucasian railway has provided a safe trade-route to Persia, the prosperity of Erzerûm has greatly suffered. It was first conquered by the Arabs in 700, but retaken by the Byzantines fifty years later. After various vicissitudes, it fell into the hands of the Seljuks; the Mongols took it in 1241; and in 1517 it passed into the possession of the Turks. It still, however, continued to be the most important city in the country, and at the commencement of the 19th century had a population of 100,000 inhabitants. In the war of 1829, between the Turks and Russians, the taking of Erzerûm by Paskievich decided the campaign in Asia. Erzerûm was an important military centre during the wars of 1854-55 and 1877-78, and much hard fighting was done in its neighbourhood. In December 1877 the

Russians closed round the city, already hard pressed, and reduced its defenders to the utmost distress; in February 1878 it was surrendered to Russia, who held it till October, when it was restored. It capitulated to Russia in February 1916, and was reoccupied by the Turks in March 1918.

Erzgebirge ('Ore Mountains'), the name given to the chain of mountains, rich in metals, stretching SW. and NE. for 96 miles on the confines of Saxony and Bohemia, from the valley of the Elbe to the Fichtelgebirge. In the south it rises to a height of from 2500 to 3300 feet, forming a steep wall of rock; in the north it forms broad, slaty plateaus, broken by deep valleys, and gradually slopes down towards the level districts of Altenburg and Leipzig. Many of these valleys are well wooded and romantic, and occasionally fertile and thickly peopled, being watered by the Mulde, the Pleisse, and their numerous tributaries. The chain rises to its highest elevations in the so-called 'Saxon Siberia,' over against Zwickau. Here, in 12° 54' E. long., stands the town of Gottesgabe, the highest in Germany, at an altitude of 3363 feet; and here, too, are the loftiest peaks of the range (Keilberg, 4052 feet; Fichtelberg, 3980; Spitzberg, 3675). The Erzgebirge is chiefly of the gneiss-granite formation, with argillaceous and micaceous slates, porphyry, and basalt. Silver and lead are the principal metals; next come copper, tin, iron, nickel, cobalt.

Esaias. See ISAAH.

Esarhaddon. See ASSYRIA.

Esau, son of Isaac. See JACOB, EDOM, JEWS.

Esbjerg, a port of Denmark, 56 miles W. of Fredericia by rail, with a large export trade in cattle, &c., mostly to England. Its harbour, the only one of importance on the west coast of Jutland, was constructed by the state at great expense in 1868-88. Pop. 19,000.

Escalade (Lat. *scala*, 'ladder'), in siege operations, a method of gaining access to the enemy's works; passing ditch, curtain, bastions, by means of ladders. See FORTIFICATION, SIEGE.

Escanaba, a city and port of Michigan, on Green Bay, with a great iron-ore trade; pop. 13,000.

Escarp'. See FORTIFICATION.

Escarment, a long line of cliff, formed by the outcrop of a relatively hard stratum of rock interbedded amongst more yielding strata, the dip or inclination of which is generally gentle. This structure is the result of denudation—the hard rock projects simply because it has yielded less readily to the agents of erosion. In a country composed of an alternation of such relatively hard and soft rocks, dipping in one and the same direction, we usually meet with a succession of escarpments, with their steep faces all turned towards the direction to which the strata rise, while the ground falls away with a gentle slope in the direction of the dip or inclination of the beds.

Escars. See ASAR.

Eschar (Gr. *eschara*), a slough or portion of dead or disorganised tissue, is commonly applied to artificial sloughs produced by the application of caustics. *Escharotic* means causing an eschar.

Eschatology (Gr. *eschatos*, 'last,' and *logos*, 'a discourse'), the doctrine of the last things, a theological term for what Scripture reveals and Christian speculation has concluded about a future state. But although the term is thus limited, an eschatology existed among all the great nations of antiquity, dark and ill defined as in the Greek, or elaborate as in the Egyptian religion. Together with it grows up more or less definitely the idea of retribution. For an account of the more elementary

forms of this conception, see TRANSMIGRATION. Protestant eschatology is generally confined in practical discourses to a consideration of these four last things—Death, Judgment, Heaven, and Hell (see IMMORTALITY, RESURRECTION, DEVIL, and HELL). The principal religious parties which do not recognise eternal punishment as a Scriptural doctrine are treated at UNIVERSALISM and CONDITIONAL IMMORTALITY; the question of an intermediate state, at PURGATORY. See also MILLENNIUM, and the bibliography appended to HELL.

Escheat (Fr. *échoir*, from Lat. *cadere*, 'to fall or happen'), an incident of the feudal law whereby, when there was no tenant qualified to perform the services, land reverted to the lord. In England, escheat took place *per defectum tenentis*, as e.g. when the tenant was convicted of a capital felony; this kind of escheat 'with attainder' was abolished in 1870, as also the Forfeiture (q.v.) of land to the crown for high-treason (see ATTAINDER). According to the existing law, a criminal's property is forfeited only in so far as may be necessary for the purpose of making compensation; but the old doctrine of 'corruption of blood' is now entirely done away; no person is barred by the crime of his ancestor from succeeding to property. Escheat still takes place *per defectum sanguinis*, for want of heirs, when the owner (the feudal tenant) of land dies intestate, leaving no heir; in such case the feudal superior (usually the crown) may claim the land. When land falls to the crown, the 'prerogative of grace and bounty' is sometimes exercised in favour of persons having claims on the deceased; subject to this prerogative the land becomes part of the crown-lands, and the profits are carried to public revenue.

Escheat in Scotland is of two kinds: (1) The total forfeiture to the crown of all property heritable and movable belonging to a person who has been convicted of treason. (2) It signifies the forfeiture of goods by a debtor who has failed to make payment of debt in obedience to legal Diligence (q.v.). This species of escheat for debt was abolished by 20 Geo. II. chap. 50. It was of two kinds: single escheat, and liferent escheat. By the former, all the debtor's movables were forfeited to the crown; by the latter, the annual profits of the debtor's estate were forfeited to the superior. Single escheat still exists in Scotland as a punishment of crime. In all capital convictions it is ordered that the prisoner's 'whole movable goods and gear be escheat and inbrought to his majesty's use.' In cases of forfeiture, bigamy, perjury, and some others, single escheat is imposed by statute as a portion of the penalty on conviction. Single escheat also falls upon denunciation for outlawry; and, if the rebel continues for a year under denunciation, his liferent escheat falls to his superior.

In the United States, the rules of feudal tenure are, for the most part, obsolete; but all property, real or personal, which is left without a legal owner, is claimed by the state in which it is situated.

Eschenbach, WOLFRAM VON. See WOLFRAM VON ESCHENBACH.

Eschscholtz Bay, the innermost part of Kotzebue Sound, in Alaska, barely outside the polar circle. It was named after the naturalist Johann Friedrich Eschscholtz (1793-1834), who sailed with Otto von Kotzebue.

Eschscholtzia, a genus of Papaveraceæ, of which *E. californica* and other species are common as showy garden annuals.

Eschwege, a town in the Prussian province of Hesse-Nassau, on the Werra, 40 miles ESE. of Cassel by rail. It has manufactures of woollen, cotton, and linen fabrics, of machines, and of

tobacco; also tanneries, and some trade in fruit and pork, and agricultural produce. Pop. 13,000. The town was twice plundered and once burned during the Thirty Years' War.

Eschweiler, an industrial town of Rheinland, 8 miles ENE. of Aix-la-Chapelle, has important iron, zinc, and tin works, machine-shops, manufacturing for making copper plates, needles, wire, gas-pipes, and firebricks, besides tanneries and breweries. In the vicinity are productive coal-mines. Pop. 26,000.

Escobar y Mendoza, ANTONIO, Spanish casuist, was born at Valladolid in 1589. Entering the order of the Jesuits in 1604, he became celebrated as a preacher and writer. At his death in 1669 he left more than 40 vols. in folio, mostly in theology and morality, the principal being the casuistical *Liber Theologicæ Moralæ* (1646), which has several times been printed.

Escorial, or, less correctly, ESCURIAL, a royal palace, mausoleum, and monastery of Spain, 31 miles NW. of Madrid, on the south-eastern slope of the Sierra Guadarrama, at an altitude of 3700 feet. This immense pile of buildings, built of dark-gray granite, has a stern, austere, forbidding appearance, which is not at all relieved by the bleak, wind-swept, mountainous region in which it stands. It owes its existence to Philip II., who erected it partly to provide a royal burying-place for the kings of Spain, partly to commemorate his victory over the French at St Quentin on St Lawrence's day, 10th August 1557. Its general shape is that of a quadrangular parallelogram, 706 feet long by 550 broad, with a smaller square projecting from the east side. The current belief is that it was planned to represent a gridiron, the object upon which St Lawrence was martyred; but this has been questioned. At anyrate, each corner of the parallelogram is fenced with a tower, about 200 feet high; and above the church, in the centre of the pile, rises a cupola, its summit 312 feet from the floor. The first stone of the edifice was laid in 1563, the architect being Toledo, after whose death in 1567 his pupil Herrera carried on the work to its completion in 1584. The finest individual building is the church, a square basilica, in the shape of a Greek cross, and in the Doric order of architecture. It was formerly rich in paintings; and, although in 1837 a hundred of the best were removed to Madrid, there still remain specimens by Coello, Carabajal, Tibaldi, Zuccaro, Luca Giordano, Trezzo, Zurbaran, Ribera, Tintoretto, Titian, and Veronese. The Pantheon, or royal mausoleum, an octagonal chamber beneath the church, contains the bones of the kings of Spain from Charles V., father of Philip II., onwards (except Philip V. and Ferdinand VI.) to Alfonso XII., with queens, regents, and mothers of kings; the rest of the royal family, with Don John of Austria, are buried in the 'Panteón de los Infantes.' The library, once one of the richest in Europe, but greatly diminished by a fire in 1691, and by thefts by the French soldiery in 1808, contains many valuable MSS., including a large collection in Arabic. In the palace the most interesting apartment is the cell of Philip II., in which he spent his last days. The Escorial was again greatly injured by fire in 1872.

Escort. See CONVOY.

Escrow. See DEED.

Escutcheon (Fr. *écusson*, in contradistinction to *écu*, an ordinary shield), in Heraldry, the shield on which arms are painted; also a small representation of the knightly shield used as an armorial charge, and generally reckoned among the sub-ordinaries. The name inescutcheon in modern

heraldry is used where there is more than one such charge. From the escutcheon as a charge must be distinguished the escutcheon *en surtout*, charged with some particular coat, and placed in the centre of a heraldic shield, which is much used in marshalling of arms in regal, continental, and Scottish heraldry. Such an escutcheon, placed with the arms of an heiress in the centre of her husband's coat, is known under the name of an escutcheon of pretence. The escutcheon of pretence used in this way is unknown out of Britain.

Esdraelon, or PLAIN OF JEZREEL, a broad valley of Palestine, constituting the basin of the Kishon, extends from Mount Hermon to the slopes of the Carmel range. A flourishing and fertile region in antiquity, it is once more, after a time of neglect, highly cultivated. Here Gideon defeated the Midianites, and here in 1799 the Turks were defeated by the French.

Esdras, BOOKS OF. The Apocrypha contain two books, ascribed to Esdras, which are variously described. In the Septuagint they are described as 1st and 2d Esdras; in the Vulgate as 3d and 4th Esdras. The first of these books (1st or 3d Esdras, commonly called the Greek Esdras) is a compilation from the canonical book of Ezra, with an introduction taken from 2d Chronicles and a conclusion borrowed from Nehemiah. In the middle of the book, however, there is an original section which has nothing answering to it in our Old Testament. This section tells the story of a literary contest between three pages at the court of Darius. In reply to the question, 'What is the strongest force in the world?' the first answers, 'Wine is the strongest;' the second, 'The king is the strongest;' the third, 'Women are strongest, but above all things truth beareth away the victory.' The third answer is the source of the well-known proverb, 'Fortis est veritas et prævalebit.' The date of the composition of the book is uncertain. It must fall within the limits 160-1 B.C., but cannot be fixed more definitely. There are many chronological difficulties in the statements of the book which rather diminish its historical value, though Josephus attached so much importance to its statement that he used it for the period which it covers in preference to the canonical books.

The second book (2d or 4th Esdras) is much more important. It occupies the same place in the Apocrypha as the book of Revelation in the New Testament, and is the only specimen of apocalyptic (as distinct from prophetic) literature in it. The book exists only in the form of a Latin version, a large fragment of which was missing until it was recovered by the discovery in 1875, by Professor Bensly, of an un mutilated MS. at Amiens. The book consists of seven different visions. In its present form it has been Christianised by the addition of a Christian beginning and ending. There can be little doubt that the book was written in the reign of Domitian (81-96 A.D.), though parts of it may be of earlier origin. It deals with the problem created by the destruction of Jerusalem, 'Why hath God cast off His people?' It cannot be said that any real solution is found, but some suggestions are made in which comfort may be found: (1) We must remember our limitations, and not question the dealings of an inscrutable Providence. (2) We must trust the boundless love of God. (3) This world is not the end of things; the future life will make amends for present suffering. (4) The day of God's redemption is drawing near, when the Messiah will come and restore the kingdom to Israel.

Both books are found in the ordinary editions of the Apocrypha. A new translation, with introduction and notes, is contained in the *Oxford Apocrypha and Pseude-*

pigrapha (1913). There is a critical edition of 4th Esdras by Box. See works on the Apocrypha by Fritzsche (1860); and *The Ezra Apocalypse* (chaps. II.-XIV. of 2d Esdras), by G. H. Box (1912). The seventy verses of Esdras found by Prof. Bensly at Amiens in a 9th-century MS. are translated in Churton's *Apocryphal Scriptures* (1884), *The Speaker's Commentary* (by Lupton, 1888), and in the Revised Version (1895).

Esher, a pretty village of Surrey, on the Mole, 15 miles SW. of London by rail. Here are Esher Place, a brick gate-tower of Wolsey's palace, and Claremont (q.v.). Pop., with the Dittons, 14,300.

Esk (Cymric *wysg*, Gael. *usge*, 'water,' akin to *Eae*), the name of several small Scottish rivers. The Dumfriesshire Esk, formed by the Black and White Esks (12 and 14 miles long), runs 22 miles south-south-eastward, next 5 furlongs along the Border, and lastly 8 miles south-south-westward through Cumberland, till it falls into the head of the Solway Firth. It passes Langholm and Longtown, receives the Tarras, Liddel, &c., and affords capital fishing.—The Edinburghshire Esk, formed by the North and South Esks (17 and 19 miles long), flows 4 miles northward to the Firth of Forth at Musselburgh. Its scenery is very pretty, the northern branch passing Habbie's Howe, Roslin, Hawthornden, and Melville Castle; the southern branch Dalhousie Castle and Newbattle Abbey; and the two uniting in Dalkeith Park. The fishing is recovering from the injurious effects of the paper-mills.—Of the two Forfarshire rivers, the South Esk runs 49 miles south-eastward and eastward to the North Sea at Montrose, and the North Esk 29 miles south-eastward (over the last 15 along the Kincardineshire boundary), until at a point 4 miles N. of Montrose it likewise falls into the North Sea. Both traverse fine scenery; both afford first-rate sport; and both give earl's titles to branches of the Carnegie family—Southesk (1633) and Northesk (1662).

Esker. See **ÅSAR**, and **GLACIAL PERIOD**.

Eski-Djumna, a town of Bulgaria, 20 miles WSW. of Shumla, with a noted fair in May. Pop. 10,000.

Eskimo, a people inhabiting the whole northern coast of the American continent down to 60° N. lat. on the west, and 55° on the east, with the Arctic Islands, Greenland, and about 400 miles of the nearest Asiatic coast. Only in the southern limits of the American Eskimo region do their abodes touch the northern limit of wooded land, while to the north a tribe inhabiting the north-west of Greenland (82°-83° N. lat.) marks the most northerly limits of Eskimo distribution. The Eskimos prefer the vicinity of the seashore, from which they rarely withdraw more than 20, and hardly ever 80 miles. Their number is not ascertained with exactness, but it may amount to about 40,000. They include (1) The Western Eskimos, inhabiting the Alaska Territory and the Asiatic side of Behring Strait, rated at 20,000 souls; (2) the Mackenzie Eskimos, or Tchiglit, from Baizer Island to Cape Bathurst, 2000; (3) the inhabitants of the central regions, including the Arctic Archipelago, 4000; (4) the Labradorians, 2000; (5) the Greenlanders, about 10,000. A side branch, moreover, inhabits the Aleutian Islands, numbering some 2000; their habits and mode of life are almost like those of their Inuit neighbours, but their language, except its grammatical system, differs widely from the Eskimo. They are scattered as the sole native occupants of regions stretching from east to west as far as 3200 miles in a straight line, to travel between the extreme points of which would necessitate a journey of no less than 5000 miles. This distance, taken in connection with their homogeneous nature and manners, makes

their small bands the most thinly scattered people of the globe.

As to their bodily form, they resemble the Mongolians and the American Indians, the coast tribes serving as an intermediate link. Their height nearly equals the average of the North-west Indians. They appear comparatively taller sitting than standing. Their hands and feet are small, their faces oval, but rather broad in the lower part; their skin is only slightly brown; they have coarse black hair and very little beard. The skull is high and mesaticephalic, with a tendency in some individuals to the dolichocephalic type. Stefánsson found blond Eskimos in the south of Victoria Island, but these are probably the result of racial intermixture with European peoples, perhaps the 10th-century Scandinavian colonists of Greenland.

Though occasionally they find food by pursuing the chase on land and by fishing, the Eskimos get their subsistence mostly from hunting by sea, using for this purpose their skin-boats where the sea is open, and their dog-sledges on the ice. From the skin, blubber, and flesh of the seal and the cetaceous animals they procure clothes, fuel, light, and food. Their most interesting as well as important invention for hunting is the well-known small skin-boat for one man, called a *kayak*. It is formed of a framework covered with skin, and, together with his waterproof jacket, it completely protects the man against the waves, so that he is able to rise unhurt by means of his paddle, even should he capsize. A Greenlanders kayak is almost 18 feet long and 2 feet broad, and can carry 200 lb. besides the man. The special weapon of the kayak is the large harpoon, connected by a line with an inflated bladder. The hunter throws it when but 25 feet from the seal, and at once drops the bladder overboard, thus retarding the speed of the wounded animal, which runs off with it until finally killed by a lance-thrust.

In winter the Eskimos are undoubtedly stationary in their habits. But during the summer, when enough open water is found, they roam about in their large skin-boats, the *umaks*, which are from 25 to 37 feet long, 5 feet broad, and 2½ feet deep, and are capable of carrying from 1½ to 3 tons—the tent, with all the necessary implements for the summer household.

The winter dwellings vary with regard to the materials of which they are built, as well as in their form. In the farthest west they are constructed mostly of planks, covered only with a layer of turf or sod; in Greenland the walls consist of stones and sod; in the central regions the houses are formed merely out of snow. In Alaska the interior is a square room, surrounded by the sleeping-places, with the entrance on one side, while a hearth with wood as fuel occupies the middle of the floor. In Greenland the room is heated only by lamps, and the sleeping-places or family stalls are arranged in a row occupying one of its sides. The house for this reason is lengthened proportionally to the number of its inhabitants. Nowadays, however, the houses are not made so long as formerly—a curious fact corresponding to the disuse of the Indian 'long houses,' and like it a result of contact with civilisation. The number of inhabitants at an Eskimo station is most frequently under forty, but in rare cases more than two hundred are found. A funnel-shaped, half-underground passage forms the entrance of the narrow dwellings.

The *dress* is almost the same for women as for men, consisting of trousers or breeches and a tunic or coat fitting close to the body, and covering also the head by a prolongation that forms the hood. For women with children to carry this hood is widened, so as to make it an excellent cradle, the *amaut*. Tattooing has been general among all the

tribes, but only in the west is found the curious custom of wearing labrets, or lip-ornaments of bone or stone, inserted in holes of the lip, pierced for the purpose. The ordinary materials of which clothes are made are the skins of seals, land animals, and birds. Besides these, the intestines of seals are utilised in manufacturing an outer clothing used for waterproof coats.

The Eskimo language exhibits in a high degree the polysynthetic structure of the American tongues, characterised by the power of expressing in one word a whole sentence in which are embodied a number of ideas which in other languages require separate words. This is effected by means of radical words, to which affixes or imperfect words are attached. The Greenland dictionary contains 1370 such radicals and about 200 affixes, of which from one to ten, rarely more, can be appended to one of the former. As far as a rough estimate seems to prove, in many cases a radical may in this way be made the foundation of, strange to say, many thousands of derivatives, and a word can be composed which expresses with perfect distinctness what in our civilised languages might require twenty words. In Greenland and Labrador the missionaries have adapted the Roman letters for reducing the native language to writing.

The tribe is divided into groups constituting the inhabitants of the different wintering-places. Finally, in the same station, the inhabitants of the same house are closely united with regard to common housekeeping. In this, and perhaps similar ways, their general communism in living, characteristic of their stage of culture, is governed by rules for partnership in householding, for distribution of the daily game during the winter, and for the possessions of the individual, the family, the house-mates, and the place-fellows. One of the oldest and most respectable men, called in Greenland *ivot*, in Labrador *angajorkak*, is obeyed as chief of a house or wintering-place, although his authority, perhaps, may rest on tacit agreement only. In a similar way, more or less public assemblies constitute councils, and may be considered the courts of justice. Social organisation has been more highly developed in Alaska than in Greenland, altogether apart from the later European influence.

The Greenlanders, the greater part of the Labradorians, and the Alaska Eskimos are Christianised, but in the central groups the religion of the Eskimos is what is generally designated as Shamanism. According to the traditions of the Greenlanders, their heathen ancestors had a very distinct belief in the existence of the soul as independent of the body, and able to continue its existence after death. The souls of the deceased were venerated as guardian spirits of their surviving offspring, but besides them numbers of invisible rulers, called *inuk*, or owners of things, filled the universe. The religious observances, with the aim of propitiating or calling for assistance on these supernatural powers, consisted of *serranek* ('prayer'), *kernainek* ('invoking'), and the use of amulets. Moreover, many regulations were observed concerning modes of life, fasting, abstinence, and sacrifices (*aitsuinek*). Some people were endowed with a peculiar skill (*nalussaerunek*, 'clairvoyance') in discerning the spiritual beings and influencing them. The highest stage of this kind of knowledge was that of the *Angakoks*, or Shamans, who invoked their guardian spirits (*tornat*) by means of *torninek* ('conjuring'). A supreme being, *tornarsuk*, ruler of the *tornat*, is also spoken of, but in very indistinct terms. In Alaska religious festivals, performed by large assemblies, and with the use of masks, were held

in high esteem as a means of propitiating the invisible powers. The opposite of religious actions and *angakok* wisdom was *ilusenek* ('witchcraft'), also consisting without doubt in an application to supernatural powers, but that secretly, for selfish purposes, to the detriment of others.

The Christianised natives still preserve their ancient folklore. It represents at the same time their original poetry, religious ideas, and history, praising the deeds of their great men in braving the dangers to which their race has been continually subjected. Of this folklore considerable collections have been made, and by its study much light has been thrown on the language and on the daily life of the Eskimos, while material of the same kind has also been employed in helping to determine the difficult question of Eskimo ethnology.

The name Eskimo is said to be formed by corruption out of an Indian word signifying 'eaters of raw meat.' They call themselves *Inuit* (pl. of *inuk*, 'human being'), in Greenland partly *Kaladlit*. Their origin has been derived at different times from Europe of the glacial period, from Asia by way of the Behring Strait, but now most generally from the American continent, though the issue as between the last two can by no means be regarded as finally settled. Supporters of an American origin are at one in supposing the Eskimos to have been originally an inland people, pushed outwards by way of the river courses to the Arctic seas, where they developed their abilities as an Arctic coast people. But as to the earliest home of a peculiarly Eskimo culture, much diversity of opinion exists; some place it in the interior of Alaska, tracing a progressive development eastwards along the Arctic coast to Greenland; others find it in the district south of Hudson Bay, with a movement into Labrador, and by the west coast of Hudson Bay to the north; others, again, locate it in the Arctic Archipelago, with a movement to east, west, and north, allowance being made at the same time for the later introduction of influences from without, more especially Asiatic influences, developed first in the region of the Behring Strait.

As to the influence of the Europeans, the missionary work is mentioned above. In Greenland much care has been bestowed by the Danish government to avert the hurtful influence of contact with civilised strangers. But communism forms as essential an element in the native life as does even hunting, and, since the traditional obligations which counterbalanced its ill effects have fallen gradually into desuetude, the general result has been impoverishment. The curtailment of the houses mentioned above is owing to a rather ineffectual attempt by the natives themselves to escape this calamity.

See the article GREENLAND; also Pilling, *Bibliography of the Eskimo Language* (1888), especially for books by Beachy, Craws, Dall, H. Egede, C. F. Hall, Parry, Petitot, Ray, J. Richardson, H. Rink, and J. Ross. Besides these may be mentioned *Memoirs of Hans Hendrik, the Arctic Traveller*, translated from the Eskimo original by Dr H. Rink (Lond. 1878); Rink, *The Eskimo Tribes* (1887), and *Tales and Traditions of the Eskimo* (1875); Nansen, *Eskimo Life* (1893); Rasmussen, *People of the Polar North* (1909); Peary, *The North Pole* (1910); the Reports of the American Bureau of Ethnology; Thuren and Thalbitzer, *Eskimo Music* (1911); Stefánsson, *My Life with the Eskimo* (1913); Steensby, *An Anthropogeographical Study of the Origin of the Eskimo Culture* (1916); Rasmussen and Worster, *Eskimo Folk-tales* (1921).

Eskimo Dog, a half-tamed variety widely distributed in the Arctic regions, and much used for drawing the sledges. They are strong and powerful, like shepherds' dogs in form, with long black and white, brown, or dingy white hair. Often ill-fed and overworked, they retain much of

the original ferocity of their wolf ancestry, and are subject to fatal epidemics and to hydrophobia. Dangerous and unmanageable, they are not to be

Eskimo Dog.

compared with reindeer as aids to man, and polar explorers prefer Samoyede dogs. Yet under favourable conditions they can do 40 miles a day at 7 miles an hour, drawing over 50 lb. for each dog. The Americans have brought reindeer from Siberia to supersede the dogs in Alaska.

Eski-Zagra, or ESKI-SAGRA. See STARA-ZAGORA.

Esmeraldas (Span., 'Emeralds'), the most northerly maritime province of Ecuador, with a climate hot, moist, and on the coast unhealthy, and still largely covered with dense forest. Area, 5200 sq. m.; pop. 14,600. — The capital, Esmeraldas (pop. 5000), stands 10 miles from the mouth of the river of the same name, which is navigable to this point for ships drawing 16 feet of water.

Esné (hieroglyphic *Sne*, Gr. *Latopolis*, 'the city of the *Latus nobilis*')—the fish there worshipped—is a considerable town of Upper Egypt, and is situated on the left bank of the Nile, in 25° 15' N. lat., 36 miles above Luxor. It contains about 17,000 inhabitants, including many Copts and a large colony of dancing-girls, and has manufactories of fine cotton, shawls, and pottery. Indigo dyeing is a staple industry, and until the Egyptian troubles of 1881 and following years there was a considerable trade with the Sudan. The climate is considered particularly healthy, and invalids are frequently ordered there by the native doctors. The ancient temple, dedicated to the god Khnum, is buried beneath the accretions of the modern houses, except the noble portico or hypostyle hall, of 24 columns, four deep, which was excavated to the pavement by Mohammed Ali to serve as a gunpowder cellar. Of the older temple behind nothing is known, but Champollion ascribed it to Thothmes III. The back of the portico of the temple of Khnum presents the name of Ptolemy Philometer; but the rest is more modern, and belongs to the time of the Caesars. The sculptures are poor in design and execution. It has a Roman zodiac like that of Dendera, formerly thought to be of the most remote antiquity. At Esné is also a stone quay bearing the name M. Aurelius, while in the neighbourhood are the remains of several Coptic buildings, including a subterranean church, and a convent, perhaps the oldest in Egypt. Esné was the capital of a nome, and the coins struck in it in the reign of Hadrian, 127–128 A.D., represent the fish *latus*.—Champollion, *Not. Descr.*; Wilkinson, *Anc. Egyptians*; Mariette, *Mon. of Upper Egypt*; Lane-Poole, *Egypt*.

Esop. See *ÆSOP*.

Esotéric (Gr.) is a term derived from the ancient mysteries, in which it was applied to those doctrines that were designed for the initiated, in contradistinction to those that were imparted to the uninitiated, which were termed *exotéric*. It is now used in various relations of an analogous kind. For Esoteric Buddhism, see THEOSOPHY.

Espalier, a term borrowed from the French, and signifying a railing on which fruit-trees are trained as on a wall. Such railings are very variously constructed—sometimes of wood, sometimes of iron, sometimes of upright rails held together by a horizontal rail at top, sometimes chiefly of horizontal rails with upright posts for their support. Espaliers may be very conveniently and cheaply made of strong iron wire, sustained by upright iron or wooden posts, as in ordinary wire-fences. They vary in height from 4 to about 8 feet, according to situation and the size of the garden. On the Continent they are often constructed horizontally or at a more or less oblique angle to the sun at a few feet above the ground; but, although their introduction in this form into British gardens has been recommended by some writers, they have only been adopted here and there experimentally and with no satisfactory result. They have the advantage of securing the fruit in a great measure from the effect of winds, which often shake off great part of the crop of standard trees whilst still unripe; and owing to the full exposure to sun and air excellent fruit is produced, although there is no reflected heat as from a wall, which is therefore still superior. Espaliers are very common in gardens in Britain, and add at once to the beauty and the productiveness of a garden, the ground not being overshadowed as by standard trees, although, of course, the roots of the trees render it unsuitable for many crops to some distance on both sides of the espalier. Espaliers are often used to separate flower-borders from plots occupied by culinary vegetables. Apples and pears are considered more suitable for espaliers than any other kinds of fruit-trees commonly cultivated in Britain. The treatment is generally similar to that of wall trees, but the training is usually by horizontal branches. It is not unusual, when trees have become old and their branches thick and firm, to dispense with great part of the rails necessary in their earlier training.

Espartero, BALDOMERO, Duke of Vittoria, was born 27th February 1792, the son of a cartwright at Granátula, in La Mancha. He was intended for the priesthood, but in 1808, on the invasion of Spain by the French, he volunteered into the *Batallón Sagrado* ('Sacred Battalion') of students, and after the close of the war of independence in 1814 went to South America, where he fought against the insurgents, until Bolívar's great victory at Ayacucho in 1824 put an end to the Spanish rule on the American continent. In 1833 he declared for the succession of the daughter of Ferdinand VII., became in 1836 general-in-chief of the army in the north, viceroy of Navarre, and captain-general of the Basque provinces. Next year he drove the Carlists from before Madrid across the Ebro, defeated their forces at Luchana and Burgos, and drove Don Carlos across the frontier into France. For his success Espartero was made Grandee of Spain and Duke of Vittoria. In 1840 the queen-mother Christina was compelled to resign her office of regent, and next year Espartero was appointed by the Cortes to supply her place until the queen (Isabella) should have reached her majority. He guided the helm of the state through socialist and Carlist troubles with energy, firmness, and ability, until a combination of the Republicans and the Moderados brought about his fall in 1843.

He resided for four years in England, then, returning to Spain, lived quietly at Logroño from 1847 till 1854, when they again called Espartero to the head of the government. For two years he conducted the affairs of the nation; but in 1856 was supplanted by O'Donnell, and in 1857 resigned his dignity as senator. After the revolution of 1868, which resulted in the expulsion of Queen Isabella, Espartero gave his full and hearty support to the provisional government, though he took no part in their proceedings. In 1870 his name was put forward for the throne of Spain; but he soon withdrew it, and in 1875 tendered his adhesion to Alfonso. He died at Logroño, 9th January 1879. There is an elaborate Life by Florez (Madrid, 1843-45).

Esparto (*Stipa tenacissima*), a grass nearly allied to the well-known and beautiful Feather-grass (q.v.), a native of the south of Europe (especially Spain, between Alicante and Málaga) and North Africa (between Oran and Tripoli).

Esparto Grass
(*Stipa tenacissima*).

From very ancient times it was used on both sides of the Mediterranean for the making of carpets, sandals, ropes, baskets, nets, and sacks, and as a substitute for horse-hair; but its chief application is now as a material in paper-making (see PAPER). The grass grows wild, requires little rain, and is pulled once a year; but two crops are taken in some parts of Spain, where it has also been the practice to pluck, not cut, the plant. It covers large areas from the seashore up to a considerable altitude, and accustoms itself to the poorest rocky and sandy soils. Some species of *Stipa* are valued as fodder in

the drier parts of the United States, though the ripe awns are apt to be troublesome to stock.

The name *esparto*, the Spanish form of the Latin *Spartum*, as well as the Arabic name *halfa* now naturalised in French, is also applied, especially in Tunis and Tripoli, to another somewhat similar and related grass, *Lygeum Spartum*, more accurately known, however, in French as *Albardine* and in Arabic as *Senec*. A third grass, also of similar habit, uses, and distribution, is the Byss (*Ampelodesmos tenax*). In Egypt the name *halfa* is applied to *Eragrostis cynosuroides*.

Esperanto. Among the numerous attempts which have been made during the past 300 years to establish an international or universal language, the greatest measure of success has attached to the project of Dr L. L. Zamenhof, author of 'Esperanto,' a language which seems likely to realise in great part the hopes of its inventor. The reason of the success of Esperanto, after the failure of so many attempts, lies in the soundness of the principles on which it is compiled, which may be summarised in the words, simplicity and internationality. Nearly every element in Esperanto is drawn from the natural languages, and the roots are so chosen that a great majority of them are

common to several of the principal languages of Europe; on the other hand, grammar and phonetics are reduced to the simplest and easiest form.

The foundation of the language consists of some 2000 roots, about 30 affixes (which are also regarded as independent roots), and 16 grammatical terminations. The affixes are so chosen as to allow a great reduction in the number of necessary roots; for example, the prefix 'mal-' which reverses the meaning of a root, has a great effect in reducing the vocabulary (*malgranda*, small; *malfidi*, mistrust; *malofte*, seldom). They can be used in conjunction with any roots as required, and on the agglutinative principle, producing such words as *en-ir-eg-o*, place of entrance; *mal-jun-ul-in-o*, old woman. All nouns end in -o, adjectives in -a, derived adverbs in -e (*amo*, love; *ama*, loving; *ame*, lovingly). Nouns and adjectives take -n for the objective case, -j (pronounced y) for the plural. The verb has 11 forms, including six participles.

The vowels are reduced to five, *aeiou*, pronounced approximately as in father, very, pique, glory, rule. Consonant sounds are rather plentiful, as they include practically all those found in English, except th, dh, and include Scots ch (loch) in addition. Six of them are represented by accented letters, ĉ ĝ ĵ ŝ ŭ ŭ. Every letter has one sound, which is, so far as is practicable, invariable, and there are no digraphs.

In addition to the fundamental roots, the language includes all such words as telephone, photograph, which are already international, and a number of roots which have gradually been introduced in the course of everyday use. Scientific terms, for the most part, are already international, and only need adapting to the esperanto phonetic system. The result is a language of remarkable richness and flexibility, as well as of extreme simplicity and regularity. The following are simple examples:

1. La instru-isto mal-permes-is la uzon de tiu instru-isto.
The instruct-or dis-allow-ed the use of that dangerous gas.
dangerous gas.
2. Por esti sukcesa politikisto, oni ne devas esti timema.
To be a successful politician, one must not be timorous.

Esperanto was first published by its author, at the age of twenty-eight, in the year 1887, and its nucleus has remained practically unaltered since that date. The author, whose purpose was purely idealistic, gave up all right to personal profit from his invention; but his constant advice and strenuous work guided its development along conservative lines until his death in 1918.

Esperanto has proved itself capable of fulfilling the purposes for which it was designed, as it is used by a large and increasing number of persons for practical purposes, whether for commerce, study, or recreation. Its practical usefulness as a spoken language has been amply shown at the many congresses which have been held, representing some thirty nationalities. It also has a growing literature, of which the most important part consists of translations. Those of Dr Zamenhof himself, consisting of classical prose or poetical works from six languages, are the best known. Its headquarters are in Geneva.

See R. J. Lloyd, *The Esperanto Language*; B. E. Long, *The Passing of Babel*; Major-General G. Cox, *Grammar and Commentary*.

Espinasse. See LESPINASSE.

Espinel, VICENTE DE (1551-1624), poet and musician, was born at Ronda in Granada, studied at Salamanca, and as a soldier in Flanders met with some of the adventures related in his *Vida y*

Aventuras del Escudero Marcos de Obregon (1618; trans. 1816), largely drawn upon by Lesage (q.v.). Taking holy orders, he became—nominally—chaplain to a hospital. His poems are chiefly lyrics.

Espirito Santo, a small maritime state of Brazil, lying immediately to the north of the state of Rio de Janeiro. Area, 17,000 sq. m.; pop. 210,000. The surface is mostly flat and swampy, the climate moist and hot, and the vegetation luxuriant.

Espirito Santo. See NEW HEBRIDES.

Espy, JAMES POLLARD, meteorologist, born in Pennsylvania in 1785, for a time practised law and taught classics. His theory of Storms (q.v.) was embodied in the *Philosophy of Storms* (1841). Appointed in 1843 to the Washington observatory, Espy there laid the basis of the Weather Bureau. He died 24th January 1860.

Esquimalt, a port at the south end of Vancouver Island, on Juan de Fuca Strait, 3 miles from Victoria (q.v.). It has a magnificent harbour, is a Canadian naval station, and is strongly fortified. Pop. 5000.

Esquimaux. See ESKIMO.

Esquire (Old Fr. *escuyer*, 'a shield-bearer'), originally the shield-bearer or armour-bearer of a knight. A knight fully equipped was in the days of chivalry attended by two esquires, whose spurs were of silver, not of gold, like the knight's. And when the sovereign created esquires, silver spurs were placed on their heels, and collars of SS round their necks. Blackstone quotes with approval Camden's definition of four classes of esquires: (1) 'The eldest sons of knights, and their eldest sons in perpetual succession. (2) The eldest sons of younger sons of peers, and their eldest sons in like perpetual succession. (3) Esquires created by the king's letters-patent or other investiture, and their eldest sons. (4) Esquires by virtue of their offices, as justices of the peace, and others who bear any office of trust under the crown.' To these Blackstone added the esquires of Knights of the Bath, no longer appointed. Camden's third class no longer exists. Christian, in his notes to Blackstone, would limit the holders of 'offices of trust under the crown' to those who are styled esquires by the king in their commissions, and he remarks Blackstone's omission of barristers, who have been held by law to be esquires by office. In common usage the designation of esquire is very widely and very loosely applied.

Esquirol, JEAN ÉTIENNE DOMINIQUE (1772-1840), born at Toulouse, was appointed physician to the Salpêtrière at Paris in 1811. He lectured and wrote on the diseases of the brain and their cures, and in 1825 he became first physician to the *Maison des Aliénés*, while managing his private asylum at Charenton. His influence on the treatment of the insane was very powerful for good.

Esquiros, HENRI ALPHONSE, a French poet and politician, was born at Paris, 24th May 1814. At twenty he made his début with a volume of poems, which was followed by two romances, *Le Magicien* (1837) and *Charlotte Corday* (1840). His *Évangile du Peuple* (1840), a democratic commentary on the life of Jesus, cost him eight months' imprisonment and a fine of 500 francs, but gave him leisure and inspiration for his *Chants d'un Prisonnier*. His *Vièrges Folles*, *Vièrges Martyres*, and *Vièrges Sages* (1841-42) showed further his socialist sympathies. After the revolution of February 1848, Esquiros was elected a member of the Legislative Assembly, but the *coup d'état* of 1851 drove him to England, where he gathered the materials for his *English at Home*, *Corruwall and its Coasts*, and *Religious Life in England*. Permitted

by the amnesty of Napoleon III. to return to France, he engaged in administration and in politics, but died at Marseilles, 12th May 1876.

Essad, Albanian chief, born about 1875 at El Bassan, was sprung from the house of Toptani, a family of powerful, semi-independent chiefs. Essad was throughout life consistent only in his desire for power, the rulership of Albania being his dearest aim. Having enriched himself and become a pasha in the political service of Abdul Hamid, he later turned firm supporter of the Young Turks, until the Albanian revolt assured him that his continued adhesion was hardly likely to further his ends. In the war of 1912 he championed the Turkish cause, occupied Scutari, but later relinquished it by stealth to Montenegro, on condition of subsequent recognition as ruler of a small central Albanian state. But the Albanians, mindful of Essad as exploiter and trimmer, unhesitatingly rejected his rule. Essad first supported William of Wied, but later openly and covertly opposed him. During the Great War he placed with prescience his stake on the Allies, and on the departure of the Prince of Wied, he ruled for a time in Durazzo and Central Albania; to the Serbians and Montenegrins, in their retreat before the Austrian advance, he lent his aid; and later, when not absent in Paris as president of the Albanian delegation, commanded troops in Salonika and elsewhere on the Eastern front. On the conclusion of peace he contrived that a self-styled National Assembly should proclaim him king of Albania, but apprehension at the prospect led to his assassination in Paris at the hand of an Albanian nationalist, 13th June 1920.

'Essays and Reviews,' the title of a remarkable volume published in 1860, containing the following seven papers: (1) 'The Education of the World,' by Dr Temple; (2) 'Bunsen's Biblical Researches,' by Dr Rowland Williams; (3) 'On the Study of the Evidences of Christianity,' by Professor Baden Powell; (4) 'The National Church,' by H. B. Wilson; (5) 'The Mosaic Cosmogony,' by C. W. Goodwin; (6) 'Tendencies of Religious Thought in England, 1688-1750,' by Mark Pattison; (7) 'The Interpretation of Scripture,' by Professor B. Jowett. All the writers, except Mr Goodwin, were clergymen of the Church of England, and their work, which was censured for its heterodox views by nearly all the bishops, and formally condemned by convocation in 1864, caused much excitement and controversy. Dr Williams and Mr Wilson were sentenced by the ecclesiastical courts to suspension for a year, but on appeal the sentence was reversed by the Privy-council; and Dr Temple's election to the see of Exeter in 1869 was also ineffectually opposed. The most important replies to the *Essays and Reviews* were those edited by Bishop Thomson (afterwards Archbishop of York) and by Bishop Wilberforce.

Essek (Croat. *Osijek*), the capital of Slavonia, on the right bank of the Drava, 12 miles above its confluence with the Danube, and 189 S. of Budapest by rail. The Roman *Mursia*, and the seat of a bishopric since 335 A.D., it has a prosperous trade in corn, live-stock, wood, &c. Pop. 40,000.

Essen, a town in Rheinland, 22 miles by rail NE. of Düsseldorf, stands in the midst of a rich coal and iron district. It possesses numerous establishments for manufacturing iron, chief among them being the celebrated Krupp works. See KRUPP, CANNON. Besides this great establishment there are also manufactures of tobacco, walking-sticks, and vinegar, with dye-works and breweries. Pop. 440,000. Although the industrial activity of Essen is recent, the town itself dates from the foundation of the Benedictine nunnery in 873.

The town was governed by the abess, who had the rank of a princess of the empire from 1275. After the Peace of Lunéville it was secularised, and it became Prussian in 1803. It was united with the grand-duchy of Berg in 1807, but returned to Prussia in 1814. One of the churches of the place, also founded in the year 873, presents several architectural features of interest.

Essence (Lat. *essentia*, from *esse*, 'to be'), as a philosophical term, the equivalent of the Greek *ousia*, was originally used in the same sense as *Substance* (q. v.). Later, substance came to be used for the undetermined substratum of a thing, essence for the qualities expressed in the definition of a thing; or, as Locke put it, 'Essence may be taken for the very being of a thing, whereby it is what it is.'—In Chemistry, and in popular parlance, essences are solutions of the essential oils in alcohol, and may be prepared (1) by adding rectified spirit to the odoriferous parts of plants, or to the essential oils, and distilling; or (2) simply by adding the essential oil to the rectified spirit, and agitating till a uniform mixture is obtained. Thus the essence of lemons is merely a solution of the volatile oil of lemons in rectified spirit. The term has, however, received a wider significance, and is applied to any liquid possessing the properties of the substance of which it professes to be the essence. Thus essences of coffee, beef, and rennet contain in a concentrated form the virtues of coffee, beef, and rennet, and in some circumstances may be substituted for them. See **PERFUMERY**.

Essenes (*Essēnoi*, *Essaiot*), a small religious fraternity among the Jews, whose name and origin, as well as character and history, are alike involved in obscurity. The Essenes bore one of the most momentous parts in the development of Judaism. Christianity stands in so close connection with them that John the Baptist and Christ himself have by some been pronounced to have issued from their ranks; and Islam still bears traces of an original connection. Josephus, Philo, Pliny, Eusebius, and the Fathers generally were long considered the sources, and the only sources, from which the genuine history of this fraternity could be deduced. Strange that for so many centuries the real and genuine sources—the Talmudical writings—should never have been thought of. These, together with Josephus and Philo, Pliny, Makrisi, and Abulfaraj, better enable us to form an idea of the real state of this community. Exception must be taken to the opening statement of Josephus, that there were three different 'sects' among the Jews—the Pharisees, the Sadducees, and the Essenes. The Sadducees were a political party, nothing more or less; and the Pharisees, forming as they did the bulk of the nation, cannot rightly be called a *sect*. Least of all were the Essenes such. They were Pharisees of stronger convictions, and carried out the Pharisaic views with a consistency which made them ridiculous even in the eyes of their own mother-party. The comparatively modern name of Essenes may be derived either from a Chaldee word *sacha*, meaning 'bathers' or 'baptists,' or from *asa*, meaning 'healers.' The Mishna, Beraitha, and Talmud speak of these advanced Pharisees in general as Chasidim (*Assidaioi*, 'pious men'), Nazirim ('abstinents'), and Toblé Shacharith ('hemerobaptists').

The Nazirim, a kind of voluntary priesthood, enjoining abstinence from wine, flesh, and other sensual enjoyments, had in the troublous times of anti-Syrian agitation, and the general upheaving of society, found numerous adherents; and gradually there sprang up a host of men calling themselves 'Nazirs for ever' (*Nazire olam*). Pharisees of a

spiritual and contemplative bias took this vow of Nazirship for life, and constituted themselves into a sort of religious club. Levitical purity in its strictest and highest sense made them draw closer and closer the innumerable 'fences' which the traditional law had erected round the Biblical law. Thus it became necessary, or at least expedient, that those among them who could break all ties of friendship and family should retire into a solitude not easily approachable by a stranger to their community. Food, again, could not be prepared save by those of the brethren who knew and strictly obeyed the hyper-traditional injunctions. Their dress, every implement of daily use, had to be made under similarly stringent laws of purity. A natural consequence of this their exalted notion of outward priesthood was their general celibacy. In this state of voluntary isolation, trading was out of the question: they tilled the ground, and lived on the fruits of the earth. Taking their meals, and these of the coarsest and plainest description, in common, they idealised the table into an altar, and, prayer having been said, they remained standing silently round it during the repast. That they had no individual property follows of course, and their communistic motto, which the Mishna (Aboth) has preserved to us—'Mine is thine, and thine is mine'—explains itself. We need not enlarge further on their small eccentricities—on the white linen garment, the apron, the scoop or shovel; they are one and all signs and symbols of Levitical purity. Every morning they bathed, like the priests who ministered in the temple, in pure spring-water. They abhorred blood as a source of impurity, and for this reason, probably, some of them abstained also from going up to the temple, where sacrifices were daily offered; others we find present at a festival in the temple (Succah, 51, 53). But these were but outward signs of purity, stepping-stones to inner piety, to communion with God, which was only to be acquired, according to their notion, by solitude and an ascetic life. The belief in the efficacy of the most rigid simplicity and willing self-sacrifice they held in common with the Pharisees; their horror of oaths, their frequent prayers, their occupation with mystical doctrine were their own. Untroubled by the noise of war or the strife of parties, leading a life divided between ablutions, contemplation, and prayer, despising the body and bodily wants—what more natural than that by degrees they should be led into a kind of mystical enthusiasm and fanaticism? They allegorised, they symbolised; and their efforts culminated in seeing the unseen.

Angelology, derived from the Magi, formed a prominent feature of their creed. In course of time, they were looked upon by the vulgar as saints and workers of miracles: they cast out demons, and healed the sick. Jehovah is the original light; from him proceed a number of spirits, and at their head stands the Wisdom, or *Logos*, into which, after death, the soul is again absorbed. Their code of ethics was threefold—the love of God, of virtue, and of man, their scale of perfectibility reaching its acme in the communion with the Holy Spirit—*Ruach Hakodesh* (Mishn. Sota, 99). In fine, mixing up, in the strangest manner, the most exalted and the most puerile notions, they became the forerunners of the Christian Gnostics and of the Jewish Cabbalists. One fragment of their literature alone remains; it is quoted in the Talmud (Jerusch. Berachoth) in the following words: 'It is written in the book of the Chasidim, If thou leavest it (the divine law) for one day, it will leave thee for two.'

They seem never to have numbered more than four thousand, including even those Nazirs or Essenes who remained in their own families. Their colony

appears to have been established chiefly near the Dead Sea, and it is undoubtedly this colony which has served Josephus as a basis for his romantic Essene republic. But, however distant from each other they might be, a constant intercommunication was kept up through a body of delegates, or angels (Malachim). As they had sprung from the Pharisees, so they again merged in them; the remaining part became Therapeutæ, or Christians. The Talmud reports their extinction as a separate community (Bechorot, 27).

See the Talmud, the Midrash, Josephus, Philo; Ewald, Gatz, Wellhausen, Reuss, Holtzmann, and Schurer in their relevant works; Kohler in *The Jewish Encyclopedia* (vol. v. 1903); Keim, *Jesus of Nazara*; Lightfoot on the Colossians; Zeller, who, in his *Philosophie der Griechen*, makes them indirectly influenced by non-Jewish, neo-Pythagorean doctrines; Lucius, *Der Essenismus* (Strasburg, 1881).

Essequibo, the most westerly of the great rivers of British Guiana, rises in the Acarai Mountains, 46 miles N. of the equator, and after a course of 620 miles enters the Atlantic, forming an estuary 15 miles wide, in which lie numerous fertile islands. The entrance to the river is rendered difficult owing to the sand and mud collected at its mouth; its course, which is through magnificent forest scenery, is much broken by cataracts, and it is navigable for 35 miles only. It receives a number of large tributaries, as the Rupununi, and the united Cuyuni and Mazaruni; on the Potaro, another affluent, is the grand Kaieteur Fall, 741 feet in sheer descent, discovered in 1870. The county of Essequibo, lying to the west of the river, has a coast-line of about 120 miles, nearly to the Orinoco. For frontier disputes, see VENEZUELA.

Essex, a maritime county in the east of England, washed by the North Sea, and separated from Kent by the Thames estuary, from Suffolk by the Stour. Measuring 57 miles from east to west, and 44 from north to south, it has an area of 1530 sq. m. The low flat sea-board is close on 100 miles long, deeply indented by shallow creeks, and much of it fringed by the desolate salt-marshes described so well in Baring-Gould's *Mehalah*. Inland the surface becomes gently undulating or even hilly, the principal eminences being Danbury Hill (317 feet), Laindon Hill (378), and High Beech (350). The rivers are the Thames, Stour, Lea, Stort, Colne, Blackwater, Crouch, Roding, and Chelmer—rivers that sometimes flood the low-lying lands. Chiefly occupied by the stiff London Clay, but with chalk in the north-west, and crag near Harwich, Essex offers a great variety of soil. Almost four-fifths of the entire area is in cultivation; and as Essex is more than most counties purely agricultural, so it has suffered more than most through agricultural depression. Near London are suburban and manufacturing towns. Epping Forest (q.v.) is a mere remnant of the once wide woodlands, whose total area throughout the whole county is now reduced to less than 44 sq. m. Fishing is prosecuted, though not very actively; and the Colne has long been famous for its oysters. Brewing is an important industry, especially at Romford; but outside of the metropolitan area there are no great manufactures. Since 1885 Essex has returned one member to parliament for each of its eight divisions (rearranged in 1918). Chelmsford is the county town; and other towns are Colchester, West and East Ham, Walthamstow, Harwich, Southend, Leyton, Woodford, Grays, Thurrock, Romford, Maldon, Saffron Walden, Stratford, Barking, Braintree, Brentwood, Coggeshall, Dunmow, Halstead, Harlow, Ilford, Ongar, Witham. Harwich is in daily communication with the continent. 'Police London' extends into Essex; hence a recent rapid growth of population. Pop. (1801) 227,682;

(1841) 344,979; (1881) 576,434; (1921) 1,468,341. Essex, named after the East Saxons, has little history apart from Colchester (q.v.); its battlefields are Ashingdon and Maldon. The palaces of Havering and Theobalds are no more; but the Norman keep of Castle Hedingham still stands, and Audley End, a splendid Jacobean mansion. Old halls too are plentiful, and there are ruins of more than a dozen monastic houses. Essex worthies include Tusser, John Ray, Quarles, Sydney Smith, and Isaac Taylor. See histories by Moisant (2 vols. 1768), Suckling (1845), the 'Victoria History' (1903 *et seq.*), the Historical Monuments reports (1921-23), and Gepp, *Essex Dialect Dictionary* (1923).

Essex, EARL OF, a title conferred in 1572 on Walter Devereux (1541-76), scion of a very old Herefordshire house, the daring but luckless coloniser of Ulster. The title had been previously borne by the Mandevilles, the Bohuns, the Bouchiers (Devereux's ancestors), and by Thomas Cromwell (q.v.).

ROBERT DEVEREUX, Walter's eldest son and successor, was born at Netherwood, near Bromyard, on 10th November 1567, at nine was sent by Burghley, his guardian, to Trinity College, Cambridge, and at thirteen got his M.A. He had been taken to court the Christmas of 1577; in 1580 Leicester had become his step-father; and under Leicester he first saw service in the Netherlands (1585-86), for his valour at Zutphen being made a knight-banneret. Back at court, the young gallant quickly won the 'singular countenance of the elderly queen. In the words of his college-friend Bagot, 'when she is abroad, nobody near her but my L. of Essex; and at night my Lord is at cards or one game or another with her, that he cometh not to his own lodging till birds sing in the morning.' There were tiffs between them, over his bickerings with Raleigh, his duel with Blount, his stealing off to fight in Portugal, moneys lent by Elizabeth, his favouring of Puritanism, and, worst of all, his clandestine marriage in 1590 with Walsingham's daughter, Sir Philip Sidney's widow. Ere long, however, he was once more 'in very good favour,' and in 1591 commanded the force despatched to help Henry IV. in Normandy against the League; in 1593 was sworn a privy-councillor; and by 1594, thanks to Bacon, who made him his stalking-horse, was acting as a sort of foreign secretary. His was the principal glory of the brilliant capture of Cadiz (1596); but his, too, largely the failure next year of the 'Islands Voyage' (see RALEIGH). In 1597 Essex became Earl Marshal, in 1598 Chancellor of Cambridge; but meanwhile occurred his great quarrel with Elizabeth, when he turned his back on her, exclaiming that her conditions were as crooked as her carcass. A box on the ear and 'Go and be hanged' was her answer; and, clapping hand to sword, Essex vowed he would never put up with so great an indignity. They never were properly reconciled. His six months' lord-lieutenancy of Ireland proved an utter fiasco; his army of sixteen thousand dwindled to barely four; and, concluding a truce with the arch-rebel Tyrone, he hurried back to England, and burst into Elizabeth's bedchamber. She received him not ungraciously at first; still, imprisonment followed, and deprivation of all his dignities. And now he formed the mad plot for removing Elizabeth's counsellors, in pursuance of which, on Sunday, 8th February 1601, he attempted vainly to raise the city of London. On the 19th he was found guilty of high-treason, on the 25th beheaded in the Tower. Elizabeth signed his death-warrant reluctantly; but the story of the ring, given him by the queen for a safeguard, but kept back by the Countess of Nottingham, is an invention of fifty years afterwards. A patron of letters, Essex was himself a

sonneteer; and Cooper's *Athenæ Cantabrigienses* (1861) gives a longish list of his writings. See the authorities cited there and in our articles BACON and ELIZABETH.

ROBERT DEVEREUX, eldest son of the preceding, was born in January 1591, and in 1604, soon after James I.'s accession, was restored in blood as third Earl of Essex. When just fifteen he was married to a daughter of the Earl of Suffolk, but during his two years' travels on the Continent (1607-9) she and Carr fell in love, and on getting a divorce she married him (1613). See OVERBURY. Essex's own second marriage (1631) was almost as unhappy as the first. From 1626 he had attached himself to the popular party, and the Long Parliament brought him to the front; in July 1642, withstanding all Charles's blandishments, he received the command of the parliamentary army. A dull, worthy soul, a striking contrast to his brilliant sire, he was brave enough personally, but a very poor general; and to his hesitancy and inactivity the prolongation of the war was largely due. The drawn battle of Edgehill, the capture of Reading, and the relief of Gloucester were followed by his blundering march into Cornwall, whence he himself fled by sea. On 2d April 1646 he resigned the command, and on 14th September he died. The title died with him; but in 1661 it was revived in favour of Arthur, second Lord Capel (1631-83). See works cited at CHARLES I., and Walter Bouchier Devereux's *Lives of the Devereux, Earls of Essex* (1853).

Esslingen, a manufacturing town of Württemberg, on the Neckar, in the centre of a pleasing and fertile district, 9 miles by rail ESE. of Stuttgart. It consists of the inner town, which retains much of its old walls and towers, and of several suburbs, embosomed in gardens and vineyards. The chief buildings are the old citadel, the Liebfrauen Church (1440)—a splendid Gothic edifice, with a beautiful spire 246 feet high—the old (1430) town-house, and the new (1742). It has the greatest machine-shops in the state, a lithographic establishment, and manufactures of a wine called Esslingen champagne, of woollens, of cotton and woollen yarns, lackered iron, silver-plate, and tin wares, with a good trade in wine and fruit. Pop. (1875) 19,602; (1919) 37,814. Esslingen was founded in the 8th century, and received in 1209 the rights of a free city of the German empire. During the 15th century it was engaged in a bitter contest with the counts and dukes of Württemberg. In 1802 the town, with its territory, was assigned to the duchy of Württemberg.

Estaing, CHARLES HECTOR THÉODAT, COMTE D', naval officer, was born in Auvergne in 1729, became brigadier in 1756, and afterwards served in the East Indies with Lally. In 1778, as vice-admiral, he sailed with sixteen vessels to co-operate with the colonists against the British. He captured St Vincent and Grenada in 1779, but his efforts on the mainland were uniformly unfortunate; and in 1780 he returned, severely wounded, to France, where he persuaded the ministry to send 6000 men to the colonists' aid. His loyalty to the royal family, and especially to the queen, outweighed his services to his country, and he was guillotined in Paris, 28th April 1794.

Estate, in the law of England, is the state or legal relation in which a person stands to his property, or, in other words, the quantity of interest he has in it. The first division of estates is into legal and equitable. By the former is signified the estate which a man has by the com-

mon law; by the latter, the interest which has been created by the operation of a court of equity (see EQUITY, USES, TRUST). Estates in land may be considered with reference to the quantity of the estate, the time of enjoyment, and the number of persons who may unite in the enjoyment. Under the first head, estates are either freehold or less than freehold. Freehold estates, again, are divided into freeholds of inheritance, or Fees (see FEE), and freeholds not of inheritance, or for life. An estate for life may be for the life of the person to whom it is granted, or for that of another person, or for more than one life. A person holding an estate for the life of another is called tenant *pur autre vie*. An estate *pur autre vie* granted to a man and his heirs descends, in case of the death of the tenant intestate, during the life for which he holds to his heir. An estate by the courtesy of England, and an estate in dower, are estates for life. A conveyance by deed to A. B., without words giving him an estate of inheritance, makes the grantee tenant for life. An estate to a woman during her widowhood, or to a man until the occurrence of a specified event, as till he receive a benefice, will be construed to be an estate for life, but the estate is determinable on the event happening. Tenants for life are entitled to take Estovers (q.v.), but they must not commit Waste (q.v.). The representatives of a tenant for life are also usually entitled to take the emblements on the expiry of the term. Estates less than freehold are called also chattels real. This species of estate, on the death of the tenant, passes, like other Chattels (q.v.), to the executor, and not to the heir. They are divided into estates for years, estates at will, and estates on sufferance (see LEASES). Estates, with reference to the time of their enjoyment, may be either in possession or in expectancy. An estate in possession comprehends not only an estate in the actual occupation of the tenant, but one from which he has been wrongfully ousted. In this latter case the law regards the rightful tenant as having the actual estate, to which is attached the right of entry. An estate in expectancy may be either in Reversion (q.v.) or Remainder (q.v.). Estates of this character form a large portion of the rights to land in England, and are the subject of some of the most subtle learning of the English law. With reference to the number of persons entitled to the enjoyment, estates may be in severalty, in joint-tenancy, in co-parcenary, or in common. An estate in severalty is where the sole right to the estate is in a single person. See CO-PARCENARY, LAND-LAWS, REAL, TENURE.—For the Estate Duty as now levied, see DEATH DUTIES.

Estates of the Realm, not King, Lords, and Commons, as is often said, but the Lords, the Clergy or Spirituality, and the Commons, which estates, together with the king or queen, form the parliament of the United Kingdom of Great Britain and Ireland. (For an apology for the common error, see Lister's *Life of Clarendon*, vol. i. p. 190-196; see also the article PARLIAMENT.) The ancient parliament of Scotland consisted of the king and the three estates of the kingdom, by which latter was meant—(1) the archbishops, bishops, abbots, and mitred priors; (2) the barons, under which head were comprehended not only the nobility, but the commissioners of shires and stewards; and (3) the commissioners from the royal burghs. In Sir David Lindsay's *Satire of the Thrie Estaitis*, it is before Spirituality, Temporality (landholders), and Burghes that John the Common Weill makes his complaint. The expression *Fourth Estate* for the newspapers is ascribed by Carlyle to Edmund Burke, who said that in the reporters' gallery there

was a fourth estate more powerful than any of the other three. In France the nobles, the clergy and the third estate (*tiers état*) remained separate down to 1789 (see FRANCE); in England the greater clergy became Lords Spiritual, the lesser clergy became, for political purposes, part of the Commons, and parliament was organised in two houses. In Sweden there were, till 1866, four estates or houses—nobles, clergy, citizens, and peasants.

Estate Tail. See **ENTAIL**.

Es'te (ancient *Ateste*), a town of Italy, on the southern slope of the Euganean Hills, 17 miles SSW. of Padua. It is an old place, with a decidedly Lombard appearance, many of the houses being supported by arches. Its most interesting buildings are the *Rocca*, or castle, overhanging the town, and a Romanesque church, surmounted by a leaning campanile. Este has some manufactures of porcelain and faience wares. Pop. 12,000.

Es'te, one of the oldest and most illustrious families of Italy, possibly of Langobard origin, whose heads from an early date ranked as keepers of the marches of upper Italy, and afterwards received from the emperors several districts and counties, to be held as fiefs of the empire. In 1097 the family divided into two branches, the German and Italian. The former was founded by Welf IV., who had received the investiture of the duchy of Bavaria from the Emperor Henry IV. in 1070. From him are descended the Houses of Brunswick and Hanover, and consequently the sovereigns of Great Britain, also called Este-Guelphs (see **GUELPHS**). The Italian branch was founded by Welf's brother, Fulco I.; and for several centuries the history of the Este family as heads of the Guelph party is interwoven with the destinies of the other ruling families and small republics of Northern Italy. During this period they first gained possession of Ferrara and the march of Ancona, and afterwards of Modena and Reggio, and were widely celebrated as the patrons of art and literature. Among the most illustrious members of the family was Alfonso I. (died 1535), equally distinguished as a soldier and a statesman, and celebrated by all the poets of his time, particularly by Ariosto. His second wife was the notorious Lucrezia Borgia. A quarrel with the Popes Julius II. and Leo X. brought about the forfeiture of his papal fiefs, which were restored by Charles V. after the siege of Rome in 1527. His successor, Ercole II., who married Renate, daughter of Louis XII. of France and Anne of Brittany, attached himself to Charles V. His brother, a dignitary of the Catholic Church, erected the magnificent Villa d'Este at Tivoli. The next prince, Alfonso II. (died 1597), would have been noways inferior to the preceding but for his immoderate love of splendour, his inordinate ambition, and the cruelty he displayed towards the poet Tasso. Rinaldo (died 1737), by his marriage with Charlotte of Brunswick, united the German and Italian houses, separated since 1070. The male line of the House of Este became extinct on the death of Ercole III. in 1803, whose only daughter married the Archduke Ferdinand, third son of Francis I. of Austria. Their eldest son, Francis IV., by the treaty of 1814-15, was restored to the duchy of Modena, and on his mother's death obtained the duchies of Massa and Carrara. He was succeeded in 1846 by his son, Francis V., who in 1859 was obliged to resign his territories to Victor Emmanuel. With the death of Francis V. in 1875 the Austrian branch also became extinct.

Estella, an ancient city of Spain, in the province of Navarre, on the Ega, 27 miles SW. of Pamplona. Pop. 5600. Here Don Carlos was proclaimed king in 1833; and Estella was again the Carlist headquarters from 1871 to 1876.

Estepa, a town of Spain, 60 miles ESE. of Seville; pop. 8000.

Estepona, a maritime town of Spain, 26 miles NNE. of Gibraltar. It supplies Gibraltar with fruits and vegetables. Pop. 10,000.

Esterházy de Galantha, one of the most powerful families of Hungary, raised in the 17th century to the rank of princes of the empire. The family divided into three main branches—the Csesznek, Altsöhl or Zolyom, and Fiaknó or Forchtenstein lines. Count Paul Esterházy of Fiaknó (1635-1713) served in the Austrian army with such distinction as to gain a field-marshal's baton at the age of thirty, and for his successes against the Turks, and still more for his support of the House of Hapsburg, was made a prince of the empire in 1687. A descendant, Prince Nicholas Joseph (1714-90), is best remembered for his thirty years' patronage of Haydn (q.v.). His grandson, Prince Nicholas IV. (1765-1833), founded the splendid collection of pictures at Vienna, and by this and other expenses brought his vast estates into sequestration. Napoleon, in 1809, offered him the crown of Hungary. His son Prince Paul Anton (1786-1866), who represented the Austrian government at London in 1815-42, added greatly, by his profusion, to the burdens imposed on the family property.

Esters, or **ETHEREAL SALTS** (also 'compound ethers'), are carbon compounds formed by the union of acids and alcohols, as in inorganic chemistry the metallic salts are formed by the union of acids and metallic hydroxides. Thus when ordinary alcohol (methyl alcohol) and strong hydrochloric acid are mixed and heated they combine and produce ethyl chloride (an ester) and water. Instead of the acid itself its chloride may be employed. Esters may be saponified or hydrolysed when heated with water or caustic soda solution, an alcohol and salt of the acid being formed.

Esther, **THE BOOK OF**, contains the story of a great deliverance of the Jewish people in Persia through the influence of Queen Esther, who had succeeded Vashti as the favourite wife of Ahasuerus (Xerxes). Haman, the grand-vizier of Persia at the time, irritated at the refusal of the Jew Mordecai to pay him proper homage, devised a plan for exterminating the Jewish people in Persia and confiscating their property. However, through the influence of Esther, who was a Jewess and a kinswoman of Mordecai, Ahasuerus was persuaded to repeal the edict and issue another protecting the Jews. Haman's policy was reversed, and he himself was hanged upon the gallows which he had prepared for Mordecai. The Book of Esther is thus a manifesto of Jewish patriotism, and it became so popular that its annual reading in the synagogue was one of the chief events connected with the celebration of the feast of Purim. It was one of the last books to be admitted into the Jewish Bible, and its right to a place in the canon was questioned for some time. The book had less attraction for the Christian Church than for the Jewish people. It is never quoted in the New Testament, and its authority was often called in question—e.g. by Melito of Sardis, Athanasius, Gregory of Nazianzus. Luther spoke very disparagingly about it: 'Though they have this book in the canon, in my judgment it deserves more than all to be excluded from the canon.' 'I am so hostile to the book that I would it were not in existence, for it Judaizes too much and hath a great deal of heathenish naughtiness.' These criticisms are largely due to the absence from the book of any definite religious teaching. The name of God is never once mentioned, though the king of Persia is referred to no less than 187 times. Modern criticism is disposed

to question the historicity of the narrative, and regard it as a romance or religious novel, like the book of Judith in the Apocrypha, which in some respects it very closely resembles. There is absolutely no corroboration of the story to be found in any other accounts of Xerxes or of the Jewish people in Persia. If the drama of Esther were historical fact, there would have been some reference to the heroine in Chronicles, or Ezra, or Daniel, or Ecclesiasticus, or Philo. The complete silence of our other authorities is inexplicable on the assumption that the narrative rests upon any basis of fact. The narrative too contains many intrinsic improbabilities, and is often at fault in its description of Persian customs and political organisation. Attempts have been made by some modern scholars to prove that the story of Esther had a mythological origin, and Haman and Vashti were originally Elamite deities, Mordecai represents Marduk, and Esther, Istar, the principal deities of the Babylonians. Thus Vashti and Haman on the one side, Mordecai and Esther on the other, represent the antagonism between the gods of Elam and the gods of Babylon. There is no agreement among scholars as to the exact date at which the book of Esther was written, but the prevailing opinion is that it belongs to the Greek period. The Septuagint version of the book contains lengthy additions—some 107 verses in all—which amplify the narrative, and add the religious and theological touches which are absent from the original work. These additions are included in the Apocrypha, and an annotated edition of them appears in the *Oxford Apocrypha and Pseudepigrapha* (1913), vol. i. pp. 665-684.

See *Hastings's Bible Dictionary and Encyclopædia Biblica*; Sayce, *Ezra, Nehemiah, and Esther*; commentaries in *Century Bible* and *Cambridge Bible*.

Esthonia, a republic formed in 1919 out of the Russian province of Esthonia and the northern half of Livonia, is bounded on the north by the Gulf of Finland, on the east by Russia and lakes Peipus and Pskoff, on the south by Lettland (Latvia), and on the west by the Baltic. It includes Oesel, Dagö, and other islands. About a fifth of the surface is covered with forests, moors, and small lakes, the rest being arable. The Narva, holding much power in its rapids, is the principal river, other rivers, though numerous, being mostly small and sluggish. Along the northern coast are rich deposits of oil-shale. The climate is variable, with extremes of heat and cold. The Esthonians are well educated, and there is a university at Dorpat (q.v.). The country holds an important place in the transit trade with Russia. Imports are coal, raw wool and cotton, metals, machinery, leather, oils, chemicals; exports, dairy produce, live-stock, flax, linseed, cement, timber, paper, potatoes. Agriculture is the chief occupation, the principal crops being rye, oats, barley, flax, and potatoes. The coastal waters are rich in fish, especially anchovies. Much brandy is made, and some cotton spun and wool woven. The capital is Tallinn or Reval (q.v.), the principal port. Area, 18,000 sq. m.; pop. 1,250,000. The population consists of Esths, who constitute the peasantry, and are a race akin to the Finns, and of Esthlanders, a mixed people in which the German element strongly predominates; there are insignificant German, Swedish, and Russian minorities. German was the official language and the language of the educated classes prior to 1887, when Russian, displaced by Esthonian in 1918, became the official language. In spite of six centuries of subjection to German and Russian rule, the Esths have preserved their national characteristics almost unaltered—language, customs, clothing, dwelling, physical attributes. There are two principal dialects, Dorpat and

Reval Esthonian. The people have a well-supported newspaper press, and their literature includes excellent national songs, closely resembling those of the *Kalevala*. See Neuss, *Esthnische Volkslieder* (Reval, 1850-52, and St Petersburg, 1854); *Kalevi Poeg*, edited by Kieutzwald (Dorpat, 1857); and Jannsen's *Esthnische Marchen* (1881-88). In religion they are mostly Lutherans; superstitious beliefs are widely prevalent. Esthonia was conquered by Waldemar II. of Denmark in 1219; but in 1346 it was sold to the Teutonic Knights, and incorporated with Livonia. From 1561 it belonged to Sweden, until, seized by Peter the Great in 1710, it was definitively united to his dominions in 1721. In 1917, on the first outbreak of revolution in Russia, it virtually became a federal state in a Russian confederation. Overrun thereafter by Germans and by Russian Reds, and profoundly distrustful of the Whites, Esthonia nevertheless declared (1918) and vindicated her independence. A temporary coalition government under Konstantin Pats was established in 1917. The invaders were driven out. A Constituent Assembly met in 1919; a republic was formally proclaimed; the great estates were broken up; and in 1920 peace was made with Russia.

Esthwaite Water, a lake in the extreme north of Lancashire, 9½ miles W. by N. of Kendal, between Windermere, into which it drains, and Coniston Water; 217 feet above the level of the sea, it is about 1½ mile long by ½ mile wide, and has a maximum depth of 80 feet. It is associated with Wordsworth's school days at Hawkshead.

Estienne. See STEPHENS.

Estoile, or STAR, in Heraldry, is distinguished from the Mullet by having six waved points, while the latter consists of five plain points.

Estoppel, a conclusive admission, which cannot be denied or controverted by the party whom it affects. Coke says that it is so called 'because a man's own act or acceptance stoppeth or closeth up his mouth to allege or plead the truth.' Estoppels are usually divided into three kinds—(1) By matter of record, where any judgment has been given in a court of record, the parties to the suit are estopped from afterwards alleging such matters as would be contradictory to the record. Where the judgment is wrongfully signed, the remedy is to apply to the court to set it aside. (2) By matter in writing. Thus, a party who has executed a deed will be precluded from afterwards denying, in any action brought upon that instrument, the fact of which it is evidence. (3) By matter in *pays*, as by acceptance of an estate, where, e.g., a tenant cannot dispute his landlord's title, or, a licensee of a patent is estopped from denying the patentee's right to the patent. Besides these, some other modern rules are referred to the doctrine of estoppel. Where a man's misrepresentation or negligence induces in another a belief in the existence of a certain state of facts, and action is taken upon that belief, the person guilty of misrepresentation or negligence is estopped or barred from denying the existence of that state of facts. Thus, the acceptor of a bill of exchange is barred from denying the handwriting of the drawer; and, where a person draws a cheque in so careless a way that the amount may be easily changed, he is estopped by his own negligence from suing his banker for paying any so increased amount. There is, further, equitable estoppel, or estoppel by acquiescence, where a person, by tacitly representing his own position to be more favourable to another than it is, has induced that other to act on the belief that the representation is true. The doctrine of estoppel prevails in America as well as in England. In Scotland, also, the same principle is recognised, under the name of Personal Excep-

tion (q.v.). See Bigelow's treatise; Everest and Strode; and the article in vol. xiii. of Lord Halsbury's *Laws of England*.

Estover, the right which a tenant has to take a reasonable portion of the wood on an estate for certain definite purposes. Estovers, or *botes* (Saxon), are of three kinds—housebote, which is twofold—viz. *estoverium ædificandi et ardendi*, a right to wood for fuel and repairs of the house; ploughbote, *estoverium arandi*, wood for repairing instruments of husbandry; and haybote, *estoverium claudendi*, wood for repairing hedges and fences.

Estrays. See POUND.

Estreet (Lat. *extractum*), in English law, a true extract copy or note of some original writing or record, and specially of fines or amercements, as entered in the rolls of a court, to be levied by bailiffs or other officers. When, however, it is applied to a Recognisance (q.v.), it signifies that the recognisance itself is estreated for execution. If the condition of a recognisance be broken, the recognisance is forfeited; and on its being estreated the parties become debtors to the crown for the sums in which they are bound.

Estrées, GABRIELLE D', mistress of Henry IV. of France, was born about 1571. She had already parted with her virtue before she became acquainted with Henry, in 1590. For the sake of appearances, she was married to a gentleman of Picardy, named Liancourt, from whom, however, she soon separated. The king was so fond of her that, in spite of the opposition of Sully, he was about to divorce his consort, Marguerite de Valois, in order to marry Mme. de Liancourt, when the latter died suddenly at Paris on 10th April 1599.

Estremadura, a district of Spain, lying between Portugal and New Castile, and watered by the Tagus and the Guadiana. It is bounded on the N. by Leon, on the S. by Andalusia, and since 1833 has been divided into the two provinces of Badajoz (q.v.) and Cáceres (q.v.). Area, 16,700 sq. m.; population, 1,000,000. Like the New Castilians, the inhabitants present a mixture of Mozarabic and Spanish blood, but are still graver and more taciturn than the former. The lower classes are rough and uncivilised, but honest and hospitable, modest, good-tempered, and brave.

Estremadura, a coast-province of Portugal, south of Beira, with an area of 6900 sq. m., divided into nearly equal portions by the river Tagus. The northern section is mountainous, with bare but picturesque continuations of the Castilian ranges; south of the river and along parts of the coast the country is hilly and better wooded. Many districts are extremely fertile, others utterly barren; scarcely half the province is under cultivation, but in the most favoured localities all the vegetation of middle and southern Europe flourishes. The silk-culture has greatly increased of late years; manufactures are confined to Lisbon, and this city, with Setubal, monopolises also nearly all the trade. Sea-salt, soda, and fruits are the chief exports. The other principal products of the country are wine, oil, corn, and cork; but even the sandy plains are covered with cistus, rosemary, myrtles, and other flowering and fragrant plants. It has now been divided into the administrative districts of Lisbon, Leiria, and Santarem. Pop. 1,550,000.

Estremoz, a town of Portugal in the province of Alemtejo, 23 miles NE. of Évora. It is built round the base of a hill which is crowned by a once formidable castle, erected in 1360. Estremoz is famous for its jars of red porous earthenware for keeping water cool. Pop. 8000.

Essek. See ESSEK.

Etah, an Eskimo settlement on the north-west coast of Greenland, Prudhoe Land, on Smith Sound.

Etah, a town and district of British India, in the Agra division of the United Provinces. Pop. of town, 9000. The district (area, 1737 sq. m.; pop. 900,000) consists principally of an alluvial plateau, dipping down on the east to the valley of the Ganges. There is a considerable export trade, and indigo and cotton-pressing factories. The district, which came to Britain in 1801, was early the seat of a primitive Aryan civilisation; during the mutiny of 1857 it was the scene of serious disturbances.

Étampes, a town in the French department of Seine-et-Oise, 35 miles SSW. of Paris by rail. An ancient place, with a street 4 miles long, it has a fragment of a royal castle, the 'Tour de Guinette' (circa 1160), three interesting churches, a statue of the naturalist Geoffroy Saint-Hilaire, a mediæval hôtel-de-ville, large flour-mills, market-gardens, &c. Pop. 10,000.

Étang (Lat. *stagnum*) is the name given (*Étangs salés*) to large lagoons along the French coast, frequently salt, and generally communicating with the sea by channels. See BERRE.

Étaples, a small French port and watering-place in Pas-de-Calais, 15 miles S. of Boulogne. Peace with England was made there in 1492.

Eta'wah, a town of the Doab, picturesquely situated among the ravines near the left bank of the Jumna, about 70 miles SE. of Agra, is on the East Indian Railway, and at the junction of the Agra-Mainpuri and Gwalior-Farukhabad roads. Half-hidden among trees, the town contains some handsome streets, and carries on a considerable trade. A native cloth, horn combs, and sweetmeats are manufactured. Close by are some famous Hindu places of worship, and the *ghats*, or flights of stairs leading to the river for the purpose of ritual ablution, are lined with handsome shrines. The population is about 45,000.—The district of Etawah, lying entirely in the Gangetic plain, and almost exclusively within the Doab, has an area of 1700 sq. m., and a population of some 760,000, nearly all Hindus.

Ethane, $\text{CH}_3\cdot\text{CH}_3$, a gaseous compound of carbon and hydrogen, colourless, odourless, and burning with a pale flame. Nearly insoluble in water, it is considerably more soluble in alcohol. A mixture of ethane and air is highly explosive.

Ethelbert, king of Kent, and third in direct descent from Hengist, was born in 552, and succeeded to the throne about the ninth year of his age. In a contest with Ceawlin, king of Wessex, in 568, he was defeated at Wibbandune, now Wimbledon, in Surrey. About the year 590, however, the hegemony of Kent over England south of the Humber was established. The most important events of his reign were his own conversion to Christianity, and the formal introduction of that religion into his kingdom, by St Augustine in 597. Ethelbert was also the author of the first written English laws, the collection called *Dooms* by Bede, 'which he established with the consent of his Witan in the days of St Augustine.' Ethelbert died in 616.

Etheldreda, St (properly ÆTHELTHRYTH), daughter of a king of East Anglia, was born about 630. Her second husband was Oswy, king of Northumbria. To escape, however, from the married state she withdrew first to the monastery founded by her aunt, Ebba, on St Abb's Head, and then to the Isle

of Ely (q.v.), where, in 673, she herself founded a monastic house. She died on 23d June 679, and was canonised, her festival falling on 17th October, the day of the translation of her body to its shrine in 695. Her name was popularly abbreviated or corrupted into St Audrey; and at a fair in the Isle of Ely, a common kind of lace was sold, which came to be known as St Audrey's lace. Hence *tawdry*, applied to any kind of frippery.

Ethelred I., elder brother and predecessor of Alfred the Great, was king of Wessex and Kent from 866 till his death on 23d April 871, shortly after his great victory over the Danes at Æscedune or Ashdown, a victory supposed to be commemorated by the White Horse (q.v.).—**ETHELRED II.**, the 'Unready,' was only seven at the death of his father, King Edgar, and ten when in 978 the murder of his half-brother, Edward the Martyr, placed him on the English throne, and brought about Dunstan's fall. From boyhood he was swayed by unworthy and traitorous favourites, and his reign, 'the worst,' says Freeman, 'and most shameful in our annals,' was a series of raids and invasions by the Northmen, and endeavours to buy them off with ever-increasing bribes. Still, 'Unready,' his nickname, stands for 'redeless,' deficient in counsel; of misplaced energy he had more than enough. This showed itself in his treacherous massacre of the Danish settlers on St Brice's Day (13th November), 1002, a crime that was punished by fierce invasions, until in 1014 he was forced to take refuge in Normandy. In 1002 he had married Duke Richard's daughter, Emma; the marriage was fraught with important consequences, as the earliest link between England and Normandy. Sweyn's death soon allowed his recall, but on 23d April 1016 he himself died in London. He was succeeded by Edmund Ironside, third of seven sons by a first marriage; by Emma he was the father of Edward the Confessor.

Ether, or **ÆTHER**. Many physical phenomena are supposed to be due to the propagation of a state of stress or motion through a medium filling all space. Such a medium is called an ether. The theory of propagation through an ether is the exact opposite of the theory of direct action at a distance. Newton said that it was inconceivable to him that any one who was capable of thinking correctly in such matters could admit that direct action at a distance was possible. He suggested that Gravitation (q.v.) might be due to diminution of pressure in a fluid filling space in the neighbourhood of material bodies. Lord Kelvin demonstrated that this diminution of pressure would be accounted for if we suppose that each particle of matter is a source at which an incompressible fluid is being constantly created at a rate proportional to the mass of the particle, the fluid being also constantly annihilated at an infinite distance. Or, conversely, we might suppose that the fluid is created at infinity, and absorbed and annihilated at each particle, at a rate proportional to its mass. In either case the motion of the fluid would be greatest in the neighbourhood of material bodies; but it is a known fact in hydrodynamics that, in a fluid, the pressure is least where the speed of motion is greatest. Thus the state of stress assumed by Newton would be accounted for.

Light and the so-called radiant heat are supposed to consist in waves of transverse vibrations which are propagated through the ether. Indeed, the phenomena of interference (see **LIGHT**) cannot be explained in any other way. Similarly, electric and magnetic effects are supposed to be due to the propagation of some state of stress through an ether. But it would be utterly unscientific to fill space over and over again with a new

medium for every special phenomenon which has to be explained in this way, and it seems probable that one medium can explain all. Maxwell assumed the existence of, and investigated the state of stress in, a medium through which electro-magnetic action is propagated. The equations which he obtained are identical in form with those of wave motion in an elastic solid, and the rate of propagation of an undulation is, in his theory, numerically equal to the ratio of the electro-magnetic and electrostatic units. This ratio is found by experiment to be numerically equal to the speed of propagation of light. Thus the medium which Maxwell assumed in order to explain electro-dynamic phenomena is identical, in his electro-magnetic theory of light, with the luminiferous medium; and the theory gives an explanation of reflection, refraction (single and double), and various other phenomena. Confirmation of the theory has been given by the experiments of Hertz and others, which prove the existence of these electro-magnetic undulations, and show that they have properties identical with those of light. See **ELECTRICITY**, and **LIGHT**.

In some respects the ether resembles an elastic solid; but in order to account for the immense rapidity of its vibrations when radiation passes through it, its rigidity must be excessively large compared with its density. It may be asked how, if this be so, the earth can move through the ether at the rate of nearly a million miles per day. But, as Stokes pointed out, if we consider that shoemaker's wax is so brittle that it splinters by a hammer, and that it yet flows slowly like a liquid into the crevices of a vessel in which it is placed, and that bullets sink slowly down through it, and corks float slowly up through it, the motion of the earth through the ether does not seem so incomprehensible. So it may be that the motion of planets through the ether is relatively much the same as that of a bullet moving with excessive slowness through the wax. From magneto-optic phenomena it seems certain that something of the nature of elementary rotation is going on in the ether. The elasticity above referred to must be of a rotational type.

There is no evidence of the existence of a condensational-rarefactional wave (as in the case of sound in air) in the ether. In the electro-magnetic theory it is got rid of from its velocity being infinite. In a theory of the ether advanced by Kelvin, in which it is supposed to have negative compressibility, and to be made stable by being infinite or having rigid boundaries, the speed of propagation of the condensational-rarefactional wave is zero. The question of a contractile ether had been previously considered by Green, but was dismissed by him with the statement (erroneous, as Kelvin proved) that it is essentially unstable. The theories of an ether of zero or positive compressibility lead to results which are inconsistent with experiment. On the other hand, Kelvin's theory leads to the known experimental results, as also does the electro-magnetic theory. Larmor has developed a theory (in which the elasticity is of a rotational type) which brings the electro-magnetic theory into line with recent knowledge regarding electricity and matter. In the theory of relativity the action of the ether is avoided. See **RELATIVITY**.

Ether is prepared from alcohol by the action of sulphuric acid. Alcohol is placed in a retort or still, and about an equal volume of sulphuric acid is added. Heat is at once developed by the mixing of the liquids, and on raising the temperature ether vapour passes over along with a proportion of alcohol. At the same time a stream of alcohol is allowed to pass into the still, and the heat is so regulated that a constant

temperature of about 266° (130° C.) is maintained. When five volumes of alcohol in all have been added, the temperature is allowed to rise to 286° (141° C.), at which point impurities commence to pass over. The ether so obtained contains alcohol, sulphurous acid, and water, and these may be removed by treatment with solution of chloride of calcium, &c., and subsequent redistillation.

The chemical reactions which take place in this process are of great interest, and may be divided into two stages. (1) The sulphuric acid acts on alcohol, forming ethyl-sulphuric acid and water.

Sulphuric Acid. Alcohol. Ethyl-sulphuric Acid. Water.
 $\text{H}_2\text{SO}_4 + \text{C}_2\text{H}_5\text{OH} = \text{C}_2\text{H}_5\text{HSO}_4 + \text{H}_2\text{O}.$

(2) This acid again is acted on by alcohol, with the re-formation of sulphuric acid and the production of ether.

Ethyl-sulphuric Acid. Alcohol. Ether. Sulphuric Acid.
 $\text{C}_2\text{H}_5\text{HSO}_4 + \text{C}_2\text{H}_5\text{OH} = (\text{C}_2\text{H}_5)_2\text{O} + \text{H}_2\text{SO}_4.$

From this it will be plain that the sulphuric acid is restored again, and is ready to attack alcohol anew, so as to form more ether. This process would go on indefinitely, were it not that the water liberated in the first reaction dilutes the sulphuric acid, and ultimately renders it too weak for further action.

Ether is a colourless, transparent, volatile liquid of great mobility and high refractive power, and possessing a fragrant odour and a fiery, passing to a cooling, taste. It has a specific gravity of .720 at 60° (15.5° C.), and boils at 96° (35.6° C.), forming a vapour more than two and a half times as dense as air. When reduced to a temperature of -200° F. (-129° C.) ether freezes. It volatilises spontaneously when placed in an unconfined position, as in the palm of the hand, and vaporises so quickly as to produce intense cold. Indeed, when water is covered with ether, and the latter assisted in its evaporation by being blown upon, it escapes so readily as to reduce the temperature of the water to the freezing-point. It is very inflammable, burning with a yellow-white flame; and mixed with air or oxygen, it gives rise to a dangerous explosive mixture, and hence great care requires to be taken in its distillation to keep all lights and fires out of the room where the vapours are condensing. When ether is added to its own bulk of water, briskly agitated, and allowed to settle, the two liquids appear to separate again; but it is found that the ether has taken up one-eighth of its volume of the water, whilst the latter has dissolved the same quantity of ether. It is readily miscible with alcohol in all proportions. Ether is one of the best solvents for the oils and fats, and hence is employed in analysis for the solution and separation of the oils from other organic matters, as in the analysis of oil-cakes, &c. It is also a good solvent of iodine, sulphur, phosphorus, and of strychnine and other alkaloids, as well as of corrosive sublimate and other salts.

Ether enters into combination with many acids, forming compound ethers possessing great fragrancancy, such as

Acetic Ether	$\text{C}_2\text{H}_5\text{C}_2\text{H}_3\text{O}_2$	
Butyric Ether	$\text{C}_2\text{H}_5\text{C}_4\text{H}_7\text{O}_2$	Pine-apple Oil
Pelargonic Ether	$\text{C}_2\text{H}_5\text{C}_9\text{H}_{17}\text{O}_2$	Essence of Quinces.

Enanthic ether, on which the flavour and smell of wines, brandy, &c. so much depend, has been proved to be a mixture of various ethyl ethers, chiefly ethyl caprate.

Ether is useful in the preparation of freezing mixtures, the mixture of ether and solid carbonic acid giving rise to a very low temperature indeed. When inhaled by man and the lower animals, ether first produces stimulating and intoxicating effects (it is sometimes used as an intoxicating beverage), but afterwards it gives rise to drowsiness, accom-

panied by complete insensibility; and, indeed, for some time it was the only agent used for producing Anæsthesia (q.v.) in operations, but it has been in great measure superseded by chloroform.

Etherege, or **ETHEREGE**, SIR GEORGE, one of the Restoration dramatists, was born most probably in London about 1636. Little is known of his life. He must have spent much of his youth at Paris, studied law, was 'gentle George' and 'easy Etheredge' in the circle of Sir Charles Sedley and the Earl of Rochester, the most brilliant young reprobates of their time, was on the ambassador's staff at Constantinople from 1668 to 1670 or 1671, had an intrigue with the famous actress, Mrs Barry, afterwards settling £6000 on her daughter, was knighted and married, not with his entire good-will, to a wealthy widow, and in 1686 was sent to be Resident at the Imperial court at Ratisbon. This banishment he found intolerably tedious, but he contrived to vary its monotony with courting, moderate drinking, sometimes immoderate play, and flirtation with passing actresses, as well as with correspondence with Middleton, Dryden, Betterton, and others. Fortunately, drafts of some hundred of his letters (many of these official), along with poems and other papers, have been preserved in a letter-book acquired by the British Museum in 1837, and help to reveal to us a man of whom our knowledge otherwise would have been singularly scanty. It is not true that Etheredge broke his neck at Ratisbon in 1689, by falling down-stairs after a banquet; he seems to have died in Paris, most likely about the close of 1690. In English literature Etheredge holds a place securely as the founder of the comedy of intrigue, which reached its perfection in the masterpieces of Congreve and Wycherley. He himself had found his inspiration in Molière, and out of him grew that great master of comedy's English counterpart, the legitimate comedy of manners, and the dramatic triumphs of Sheridan and Goldsmith. Etheredge was more important in the impulse he gave the drama than in the magnitude of his own performance. His habitual indolence hindered him from producing more than three plays, *The Comical Revenge; or Love in a Tub*, the earliest play of which any large part was written in rhymed heroics (1664); *She Would if She Could* (1668); and *The Man of Mode; or Sir Fopling Flutter* (1676). These were all highly popular in their day, and we have no better helps to an understanding of the time. The figures we meet are real creations, instinct with life, and some, as Dorimant and Sir Fopling Flutter, have gone into literature as concrete types of the qualities they were meant to represent. See the complete works, ed. A. Wilson Verity (1888); Meindl's study (Vienna, 1901); Gosse's *Seventeenth-century Studies* (1883); Allardyce Nicoll's *Restoration Drama* (1923); Bonamy Dobrée's *Essays in Biography* (1925).

Ethics may be briefly defined as the theory of goodness. The term is derived from the Greek word *ēthos*, which means disposition or character as well as manners or usage. The same signification belongs to the Latin word *mores*, from which Cicero formed the adjective *moralis* to translate the Greek adjective *ēthikos*. Thus in English *ethical* and *moral* are almost synonymous, although the latter term is commonly used with a less technical reference than the former. Nearly always they refer to the character or conduct of men or groups of men. But the term 'ethical' is not properly applied to every kind of inquiry into character and conduct. These are facts in the life of the individual mind and in the social order; and so long as the facts are merely described, or as their causes and effects merely are investigated,

the inquiry belongs to the science of mind—i.e. to psychology, or to the science of society, i.e. to sociology. Ethics regards the facts from a different point of view, which may be called that of appreciation, and which is expressed in judgments of worth or of goodness. Psychological and sociological judgments are descriptive, historical, or causal; but the moral judgment is always one of approval or disapproval. Thus various questions which are usually discussed in ethical treatises (such as the relation of pleasure to desire, the nature of volitional freedom, the formation of virtuous habits, the connection of moral ideas and practice with social customs and institutions) really belong to psychology or to sociology, although they may be of importance as prolegomena or as supplement to ethical study. Every ethical proposition, strictly so-called, has for its predicate the concept 'good' (or its opposite) or some other concept (right, duteous, virtuous, worthy) which involves the same meaning.

Sometimes one of these concepts and sometimes another has been regarded as the fundamental expression of the moral consciousness. Plato and Aristotle, most idealist writers, and also in general the utilitarians, have taken good as the ethical concept. To the Stoics, to Kant, and to most intuitionist writers, duty or moral law was fundamental. J. F. Herbart (*Allgemeine praktische Philosophie*, 1808) laid stress on the concept of value or worth; and his suggestions have led to the value-theory of ethics worked out by A. Meinong (*Psychologisch-ethische Untersuchungen zur Werttheorie*, 1894), C. v. Ehrenfels (*System der Werttheorie*, 1897-98), and many contemporary writers (cf. H. Münsterberg, *The Eternal Values*, 1909; W. M. Urban, *Valuation: its Nature and Laws*, 1909). These differences of treatment may affect the whole scope of an ethical system, and the mutual relation of such concepts as good, duty, worth, calls for investigation in ethical inquiry. But, whichever concept be taken as fundamental, it is clear that ethics involves a point of view or concept which is *sui generis* and foreign to the positive sciences. And there does not appear to be sufficient reason for discarding the traditional term 'good' for designating this concept.

The central problem of ethics is to determine the grounds or conditions of the valid use of this concept 'good,' and, if possible, to arrive at a reasoned synthesis of the things, or kind of life, to which goodness intrinsically belongs. Were this synthesis arrived at, the traditional problem of the *summum bonum* or chief good would be solved. Differences on this point mark the leading divergence between schools of ethical thought. But it was remarked by Aristotle, at a time when ethical terminology was less complex than it is now, that, in spite of their different views as to the nature of this good, all men are agreed as to its name: calling it *eudaimonia*—a term equivalent to 'well-being,' but unfortunately rendered, according to the universal tradition of translators, by the English word *happiness*. In modern ethical discussions the word happiness (or its equivalent in other languages) signifies a maximum of pleasures, or an experience in which the pleasures greatly exceed the pains. In this sense of the word, however, the assertion that the good is happiness would have been denied by Aristotle, as well as by Plato. While arguing that the good for man must be something obtainable by man, Aristotle did not find the end in pleasure, but rather in the perfect development of a man's self, in an activity according to moral and intellectual excellence. But the doctrine that pleasure is the highest good was held by predecessors and contemporaries of Aristotle, and was afterwards formulated by Epicurus into an ethical theory.

This view that pleasure or happiness is the chief

good has been held in two very different forms. According to the one view, good is relative to the individual: for each man it is his own happiness or pleasure; according to the other view, it is the happiness or pleasure, wherever found, of the community, or of mankind, or even of sentient creatures generally. The former was the doctrine of Epicurus, and has been called Egoistic Hedonism. The latter view—called Universalistic Hedonism or Utilitarianism—owes its development to modern and especially to English writers. A principle similar to that of modern utilitarianism was laid down very early in the history of English ethics. Thus, it has been pointed out that Richard Cumberland, in his treatise *De legibus Naturæ* (1672), put forward the 'common good of all' as the supreme end to which all rules of conduct are subordinate, though, according to him, this good includes perfection as well as happiness. In a similar way, Shaftesbury (*Inquiry concerning Virtue and Merit*, accurately published for the first time in his *Characteristics*, 1711), Joseph Butler (in his *Sermons*, 1726), and Francis Hutcheson (*System of Moral Philosophy*, 1755) speak of the 'good of society' as equivalent to virtue. In an earlier work (*Inquiry into the Original of our Ideas of Beauty and Virtue*, 1725) Hutcheson had even anticipated the utilitarian formula, afterwards made famous by Bentham, by setting up 'the greatest happiness for the greatest numbers' as the standard for goodness in conduct. But this attempt at a quantitative utilitarianism was forgotten; and the next important step was taken by David Hume (*Treatise of Human Nature*, 1739; *Inquiry into the Principles of Morals*, 1751). He defined virtue as a quality approved by the spectator, and vice as a quality blamed or censured by the spectator, and endeavoured to show, by a review of the virtues, that the qualities approved are either immediately agreeable or useful (i.e. indirectly agreeable) to ourselves or to others. In this way, utility is made the ground of the distinction between virtue and vice. The *Moral Philosophy* of Paley (1785) contributed largely to define and render applicable to practice the utilitarian criterion of morality; though, in his system, the utilitarian principle is based upon an 'other-worldly' selfishness. Subsequently, utilitarianism was defended and applied to morals, politics, and law by Jeremy Bentham (1748-1832), who was surrounded by an energetic school of writers, including Ricardo, James Mill, J. S. Mill, Austin, and George Grote. J. S. Mill's remarkable essay on *Utilitarianism* (1861) is chiefly occupied with defending the theory against the popular objections to it, which had been increased rather than obviated by Bentham's uncompromising polemics. He especially contended against the representation of utilitarianism as a selfish and a sensual theory. It is not selfish (he argued), for it requires that a man should be impartial in deciding between his own interests and those of others. It is not sensual, for man possesses faculties of a kind which sensual pleasures cannot satisfy. The being of lower faculties may have more contentment, because without the desire for anything further, but has not more pleasure or happiness. In defending this position Mill did not rely merely on the greater permanence, purity, and fruitfulness of the intellectual and social pleasures as compared with the pleasures of sense. He asserted that pleasures differ from one another in kind as well as in degree or intensity, and that the pleasure of higher quality or kind is to be preferred to one of lower quality, even although the intensity of the latter be greater than that of the former. It must be admitted, however, that this distinction is inconsistent with the hedonistic basis of utilitarian ethics, seeing that it makes not the pleasure itself, but that

which distinguishes one pleasure from another, the real ground of moral preference.

Owing to the definiteness of its principle, and the facility (within a certain range) with which it can be applied, the utilitarian maxim led, in the hands of Bentham and his school, to fruitful application to political and legal questions. The proof, or philosophical basis, of the theory presents greater difficulty. Although pleasure is an object of desire, it does not follow that this object is good and the only good; still less does the consequence hold that, because each man seeks his own pleasure, the general happiness ought to be his end. The gulf between egoistic hedonism and utilitarianism requires to be bridged over. The transition from one position to the other has frequently been made by the help of religious or of political considerations. Thus the utilitarianism of Paley was founded on the belief that the happiness of mankind was the ethical end prescribed by God; that of Bentham resulted from looking at action from the point of view of the community and its interests rather than from that of the interests of the individual. In this connection, consideration is given to the sanctions of morality, or pains following the breach of moral law. These sanctions are enumerated as religious, political, social, and internal. The religious sanction is that relied on by Paley. Bentham and Mill laid greater stress on the others. But it is admitted that the political sanction does not exact from an individual beneficence, or active regard to his neighbour's happiness, but only probity, or non-interference with that happiness. The social sanctions, again, are incomplete and variable, and have no exact correspondence with the utilitarian principle; while the internal sanctions depend on the individual conscience, which utilitarian writers commonly hold to be a growth in the individual mind, due to and imitating the social sanctions. The unsatisfactoriness of the proof of utilitarianism is recognised in the chief modern exposition of the theory—that in Sidgwick's *Methods of Ethics* (1874, 6th ed. 1901). The utilitarian theory of the moral end or standard is there associated with an intuitive theory of knowledge not usually held by utilitarians: the justification of the theory is based on the axioms of justice and benevolence, which the exhaustive examination of intuitive ethics carried out in the same work has left standing as formal axioms of the practical reason. Owing to the influence of the doctrine of evolution as applied to mind and society, a still more radical transformation has been effected in the utilitarian theory (Spencer's *Data of Ethics*, 1879—part i. of *Principles of Ethics*, 1892-93). Applied only to the method of utilitarianism in Spencer's hands, the evolution-theory has been used by other writers to show the inadequacy of the utilitarian principle. Attempts have also been made, on the basis of the theory of evolution, to establish some such ethical criterion as that of social vitality, or social equilibrium (L. Stephen, *Science of Ethics*, 1882; S. Alexander, *Moral Order and Progress*), but always without either avoiding or justifying the assumption that evolution is good or leads to the good. The inability of the theory of evolution to serve as the ground of an ethical theory was trenchantly maintained by Huxley (*Evolution and Ethics*, 1863; cf. Sorley, *Ethics of Naturalism*, new ed. 1904).

Utilitarianism is a morality of consequences: finding the criterion of goodness in the kind of feeling which actions tend to produce in sentient beings. As this pleasant or painful feeling can only be ascertained by experience, the theory is nearly always associated with an empirical theory of the origin of our knowledge of goodness. The controversies, especially of English ethics, have

been largely occupied with the debate on this question between the Empirical and Intuitive schools of ethics. The latter school lays stress on the immediateness and universality of the moral judgments passed by each man's conscience. A doctrine of the moral sense, as a feeling, or perception, by which actions or motives were morally distinguished apart from their consequences, was developed by Shaftesbury and Hutcheson; and Butler formulated the doctrine that conscience is the supreme authority as to what is right or wrong. It is true that in Butler's *Sermons* Self-love, or a calm regard to one's interests on the whole, is frequently spoken of as co-ordinate with, and indeed, in one place, as superior to conscience. But this is inconsistent with Butler's explicit statements even in that work, and the view does not reappear in the *Dissertation on Virtue* appended to the *Analogy* (1736). In the latter work, also, the virtuous action which conscience prescribes is no longer asserted to be conterminous with action aiming at the good or happiness of society. In this way Butler's severance from utilitarianism is complete, and he may be fitly regarded as the head of the modern intuitive school. Of this school Martineau (*Types of Ethical Theory*, 1885) was a prominent representative; differing, however, from the majority of the school in holding that moral quality belongs primarily to motives, not to action. The weakness of the intuitive position, as stated by Butler and many of his successors, lies in the fact that the source of ethical principles, conscience, is not brought into intelligible relation with the rational or spiritual nature of man. Hence the force of the objection urged against Butler—that he moves in a circle, defining the right as what conscience approves, and conscience as what approves the right. The doctrine of conscience holds an insecure position in his system, because it stands by itself unrelated to reason. On this account, the position has been peculiarly liable to be undermined by empirical analyses, such as Bain's attempt (*The Emotions and the Will*, 1859; *Mental and Moral Science*, 1868) to trace the growth of conscience in the individual from fear and love with a perception of utility added, or the more elaborate efforts of evolutionist writers, by whom it is represented as the result of countless experiences of the effects of action transmitted from individual to individual, until, in the form of a moral sense or conscience, they have become part of the common mental inheritance of the race. A further difficulty connected with the view of conscience held by Intuitionists is the mutual relation of the kinds of actions it approves, or of the laws for action laid down by it. Justice, veracity, beneficence, &c. are said to be its laws; but the attempt is seldom made to show how these are connected with one another.

These obvious difficulties meet at least with an attempted solution in the ethical system of Kant (*Groundwork of the Metaphysic of Morals*, 1785; *Critique of Practical Reason*, 1788). For Kant, conscience is simply practical reason; and its laws are reduced to unity. Reason, although limited in its knowledge of objects to the phenomena of sense, is yet in the practical sphere capable of laying down absolute or unconditional laws. This is shown by the moral law, with its categorical 'thou shalt,' prescribing a principle of conduct irrespective of desire or any ulterior end. Only the action which proceeds from a good will (that is, a will in accordance with moral law) is completely good. External conformity to the law gives legality; morality requires that the law, or respect for it, should be the moving principle of action. This, according to Kant, may prove to us that the will is free; in Schiller's phrase, 'thou shalt' implies 'thou

caust.' Thus, in the order of our knowledge, it is the moral law that convinces us of freedom. But in reality the moral law is simply the law of the will itself, and the will is free when acting under its own law; it is under constraint only when influenced by the sensuous nature with which it is connected in man. The 'categorical imperative' of the moral law is expressed by Kant in the phrase, 'Act according to that maxim (or subjective principle) alone which thou canst at the same time will to be a universal law.' Reason is one in all men, and action to be rational must thus admit of being universalised. In this way reason gives a form for action. It also gives its end; for reason is an end in itself, and humanity, as rational, must therefore always be treated as an end, never as a mere means. Kant's ethical principle remains, however, a formal principle, not admitting of the connection he sought to give it with the content of practical life. This formality or emptiness is due to his purely formal conception of reason itself. To get rid of this formality has been the effort of the later ethical systems which have been most influenced by Kant. They base morality, as he did, on the reason or spiritual principle; but, with a less restricted view of this principle, they seek its content and realisation in practical life and its institutions. This position, largely due to Hegel, has been worked out independently in one of the most important English works of speculative ethics—T. H. Green's *Prolegomena to Ethics* (1883). 'The ultimate standard of worth is,' according to Green, 'an ideal of personal worth,' while, at the same time, 'it is equally true that the human spirit can only realise itself, or fulfil its idea, in persons, and that it can only do this through society, since society is the condition of the development of a personality.' According to this view morality is the gradual realisation of a spiritual principle in human character and in the forms and institutions of domestic, civic, and political life. In this way it is contrasted with the evolutionist or naturalistic systems of ethics which lay stress on natural causation as adequate for the explanation of the whole process, and which give the name morality to those habits of acting which have contributed to the preservation and development of the race. Both views are represented in contemporary ethics; and the latter or naturalistic view shows the influence of the positivism of A. Comte as well as of the theory of evolution (cf. G. Simmel, *System der Moral-Wissenschaft*, 1893). A doctrine fundamentally in harmony with intuitionism, but different from older intuitive theories in many respects, and greatly superior in the precision of thought displayed, has been put forward by G. E. Moore, *Principia Ethica* (1903).

Some of the more important ethical writings, of different schools, have been already mentioned. The best introduction to the history of the subject is Sidgwick's *Outlines of the History of Ethics for English Readers* (1886). Among text-books of ethics the following may be mentioned: J. H. Muirhead, *Elements of Ethics*; J. S. Mackenzie, *Manual of Ethics*; J. Seth, *Study of Ethical Principles*; J. Dewey and J. H. Tufts, *Ethics* (1909). See articles on the great ethical thinkers, ARISTOTLE, EPICURUS, STOICS, BUTLER, KANT, &c.; also EVOLUTION.

Ethiopia, the biblical *Kush*. Originally, all the nations inhabiting the southern part of the globe, as known to the ancients, or rather all men of dark-brown or black colour, were called Ethiopians (assumed by the Greeks to be from the two Greek words *aithō-ops*, and to mean 'sun-burned'; but it may be possibly a form of an unknown Egyptian word). Later, this name was given more particularly to the inhabitants of the countries south

of Libya and Egypt, on the Upper Nile, extending from 10° to 25° N. lat., 28° to 40° E. long—the present Nubia, Sennaar, Kordofan, Abyssinia. The accounts which the ancients have left us of this people are, even where they are not entirely fabulous, extremely scanty and untrustworthy; for though the Romans may, the Greeks almost certainly never got beyond Napata, 19° N. lat. From the Homeric age down to Ptolemy these regions were understood to be peopled by Pygmies, Troglodytes ('dwellers in caverns'), Blemmyes ('hideous men'), Macrobi ('long-lived men'), &c., besides being divided into the lands of cinnamon, myrrh, of elephant-eaters, fish-eaters, tortoise-eaters, serpent-eaters, &c. Homer frequently refers to the 'blameless Ethiopians.' The only portion of ancient records which does contain something akin to historical accounts is that which refers to Meroë, an island formed by the rivers Astaphus and Astaboras, tributaries of the Nile. There stood, from time immemorial, an oracle of Ammon. This and the central position of the island, together with the extraordinary fertility of its soil, the abundance of animals, metals, &c., made it not only the chief place of resort for all the inhabitants of the adjacent parts, especially the numerous nomad tribes, but also the emporium for India, Arabia, Ethiopia, Egypt, Libya, and Carthage. Thus it grew so rapidly that about 1000 B.C. it counted among the most powerful states of the ancient world; it not merely shook off the Egyptian yoke, but conquered Egypt, gave, under Sabako, an Ethiopian dynasty to Egypt (715), and checked the Assyrian power under Sennacherib in Palestine (701). During the reign of Psammetichus, 240,000 Egyptian artisans and traders settled in Meroë, which grew in wealth and prosperity. Many new cities were built, and the state was in the most flourishing condition when it was conquered by Cambyses about 530 B.C. Shortly thereafter Napata, situated on the Nile at the foot of Jebel Barkal, 'the sacred mountain,' was displaced by the town of Meroë from its former position as the capital of Ethiopia. After the destruction of Thebes by Cambyses, most of the inhabitants of that city took refuge in Meroë, and made the country still more Egyptian. Ergamenes transformed its theocracy into a military monarchy in the 3d century. Under Augustus, Meroë was conquered, and a Queen Candace is mentioned as his vassal. Under Nero nothing but ruins marked the place of this once powerful and highly civilised state, and it was left to modern excavators to reveal what had once been the character of this early civilisation (see MEROË).

According to the scanty native chronicles, the son of Solomon and the Queen of Sheba (Makeda as they, Balkis as the Arabian historians call her), named Menilehek, was the first king of the Ethiopians. Few kings' names occur up to the time of Christ, when Bazen occupied the throne. The missionary Frumentius (330) found two brothers (Christians) reigning—Abreha and Azbeha. During the time of the Greek emperor Justin (522), King Elezbaas destroyed the state of the Homerites in Asia, in order to revenge their persecutions of Christians, and was canonised. From 960 to 1300 another dynasty, the Zagean, held the chief power, all the members of the Solomonic dynasty, save one, having been murdered by Esal, who made her son king. In 1300 Ikon-Amlak, a descendant of this one scion of the house of David, regained possession of the throne. The later history of the country is given under ABYSSINIA. See also EGYPT, ASSYRIA.

Emigrants from the other side of the Arabian isthmus, as were, beyond doubt, the earliest settlers in Ethiopia, it is but natural that the structure

of their language, as well as that of their own bodies, should bear traces of their Semitic origin. Ge'ez (*Lesāna Ge'ez*), their oldest language, was suppressed by a royal decree of Ikon-Amlak in the 14th century, and Amharic adopted as the court language. Ever since, Ge'ez has, except in the province of Tigré, where it is still spoken with slight idiomatic changes, remained the *Lesāna Mazhaf*, the language of books and of the church. It is exclusively used in writing, even of ordinary letters, and the educated alone understand it. Its general structure comes as close to that of Arabic as a sister-dialect can and must. A great many of its words are still classical Arabic; others resemble more Hebrew and Aramaic; others, again, belong to African dialects; and many, as the names of the months,

እስመ : ከመዝ : አፋቀር : እግዚአ
 ብሔር : ለዓለም : እስከ : ወልደ :
 ቀሐይ : ወሀበ : ቢዛ : ከመ : ከሉሉ :
 ዘየአምን : ቦቱ : አይተሐጉል : አላ :
 ደረክብ : ሕይወት : ዘለዓለም ::

The text John, iii. 16, in Ethiopic, as printed by the British and Foreign Bible Society.

are Greek. It has twenty-six letters, twenty-two of which bear the ancient Semitic stamp, and exhibit the greatest likeness to the Phœnician—the common original alphabet—though no doubt derived immediately from the Sabeian or South Arabic alphabet (see ALPHABET). There are seven vowels, including a very short *e*, which sounds precisely like the Hebrew *Shēva*, when open, and like *e* in 'men,' when shut. These vowels are represented by little hooks, and remain inseparably attached to their respective letters; and as Ge'ez, unlike all its sister-languages, is never written without vowels, the alphabet becomes a syllabary with 182 characters. In addition to this, four consonants (*g*, *k*, and *h* sounds) interject a *u* sound before the principal vowel, *gua*, *guā*, *guē*, &c. Another difference exists in its being written from left to right—a circumstance from which some have concluded that the Greeks introduced writing in Ethiopia; forgetting, in the first place, that Greek itself was frequently written from right to left, and that Zend, certain cuneiforms, hieroglyphs, &c. are likewise written from left to right. As was to be expected among emigrants from South Arabia, the verbal system has most resemblances to the Arabic, although it differs from this, and agrees with Aramaic, in discarding the passive and using for it the reflexive; there is a double infinitive, only a passive participle and participial words formed by *m* prefixed; traces of a dual remain, though it is no more in use; the formation of the so-called broken plural, and of declension generally, a special accusative termination, the distinction of the subjunctive from the imperfect, and other peculiarities distinguish Ge'ez from Northern Semitic, while the want of the article distinguishes it from Arabic; and in power to subordinate clauses by means of particles and form a concatenated sentence it is superior to all other Semitic dialects. There are no diacritical marks employed in writing; the letters are not combined, and the words are separated by two dots.

Although there may have been some literature in a flourishing country like Ethiopia anterior to Christ, still, owing both to frequent internal convulsions and other causes, no traces of it remain, even the few inscriptions that have been found

being of the Christian age. The earliest existing document of post-Christian literature is a complete translation of the Bible, according to tradition by Frumentius, most probably by missionaries from the north, whose native language was Aramean (see FRUMENTIUS). The Old Testament, a translation from the Alexandrine version, or LXX., consists of four parts: (1) the Law or Octateuchos (five books of Moses, Joshua, Judges, Ruth); (2) Kings; (3) Solomon; (4) Prophets, and two books of the Maccabees. The New Testament consists of: (1) Gospels; (2) Acts; (3) Paulus; (4) Apostolus. The Book of Enoch belongs also to the literature of the Old Testament (see ENOCH), besides the Book of Jubilees, the Ascension of Isaiah, and some others. The New Testament comprises the Shepherd of Hermas, and likewise another book, Synodos, containing the pseudo-Clementine or Apostolical Constitutions, in two recensions, with the Apostolic Canons, the canons of various councils, and much other matter. The Ethiopians have a liturgy (*Kanon Kedāsē*—'Holy Canon'), and a symbolico-dogmatical work (*Harmanōta Abau*—'Belief of the Fathers'), containing portions of homilies of the Greek Fathers, Athanasius, Basil the Great, Chrysostom, Cyril, Gregory of Nyssa, and Gregory Nazianzen. Besides these they have martyrologies, called Seneksār (Synaxaria). They employ in this their sacred literature a peculiar kind of rhythm without a distinct metre. Any number of rhyming lines forms a stanza, without reference to the number of words constituting the verse, or of verses constituting the stanza. They also use certain phrases as a refrain. Ethiopic literature consists chiefly of translations, in earlier times from the Greek, and more recently from the Arabic. In the translations from Greek some interesting works have been preserved which had otherwise disappeared—e.g. the Book of Enoch. Among the translations from the Arabic are books of philosophy, medicine, jurisprudence, and history. The native literature consists chiefly of sacred poetry and chronicles, among the last the *Gloria Regum* (*Kebrā Nagast*), a work in praise of Axum and the royal family of Ethiopia (*Chronicle of Axum*). They are very fond, however, of riddles, wise saws, and the like, so fascinating to the Eastern mind. They have native vocabularies, Ethiopic and Amharic, though not of great value to the modern lexicographer. No wonder the learned in Europe should have been sorely puzzled by such a language, and that they should, after long consideration, have pronounced it to be either 'Chaldee' or 'Indian,' while Bruce held it to be the language of Adam and Eve. Potken, a Cologne church-dignitary, happening to be at Rome at the beginning of the 16th century, there made the acquaintance of native Ethiopians, and became the first to enlighten the world on the nature of this occult language. After him came the Carmelite Jacob Marianus Victorius from Reate, who wrote *Institutiones Lingue Chaldaee seu Ethiop.* (Rome, 1548), an entirely worthless book; then Wemmers, who in 1683 published an Ethiopian grammar and dictionary. The principal investigator, however, was Job Ludolf from Gotha, who, aided by the Abba Gregorius, and supported by his own extraordinary linguistic talents and indomitable energy, acquired such a power over this language that, notwithstanding the number of eminent Orientalists, such as Platt, Lawrence, Dorn, Hupfeld, Hoffmann, Roediger, Ewald, Isenberg, Blumenbach, Dillmann, &c., who have since worked in this field, his books still hold their own place. It is hardly necessary to add that Ethiopic is one of the most important and indispensable languages to the Semitic scholar.

Ancient Ge'ez is now represented by various dialects: (1) by Tigrë, which has best preserved the features of the original language, spoken in the north-east of Abyssinia, and particularly by populations just outside the north border of the kingdom; (2) by Tigrīña, or, more properly, Tigrāi, spoken about Axum, the ancient seat of the kingdom, which, however, has suffered more from the influence of Amharic; (3) by Amharic, the state language since the end of 13th century, extending far to the south, which has drawn into itself a multitude of elements from the African languages, and developed many forms altogether alien to Semitic. For the Ethiopian region, geographically, see GEOGRAPHICAL DISTRIBUTION; for the Ethiopic group, ethnologically, see ETHNOLOGY.

For excavations see books by Crowfoot and Griffith (1912); also *Annals of Archaeology* (1915), *Journal of Egyptian Archaeology* (1915, 1916), *Museum of Fine Arts Bulletin* (1917, 1918), and *Sudan Notes and Records* (1920, &c.).

Ethiopianism, a movement for completer self-realisation, originating about the close of the 19th century, among the native races of South Africa. Chief manifestations have been the secularisation of education, and a claim for a larger share in its management; the establishment, largely as the result of the influence of intercourse with the negro churches of the United States, of native churches independent of external control—e.g. the Ethiopian Church of South Africa; the rise of a Native National Congress demanding various reforms, the removal of the colour bar in especial. In 1919 admission to British citizenship, not 'independence,' was sought by the native congress.

Ethmoid Bone, one of the eight bones which collectively form the cranial box, is of cubical form, and enters into the formation of the cranium, the orbits, and the nasal fossæ; see NOSE.

Ethnology embraces a comparative study of the various races of mankind, their origin, physical and mental differences, dispersion, geographical distribution and interminglings, leaving human speech to philology, human culture (political and social institutions, usages, traditions, folklore, religion) to sociology—i.e. the science of man as a *zōon politikon* (Aristotle).

It may be stated broadly that, after the first more or less marked differentiations, whether due to the outward influences of the environment, to natural selection, the struggle for existence, the correlation of parts, or all these combined, all subsequent modifications have been mainly caused by incessant intermingling, and consequently that there are no longer any pure races in existence. (One may perhaps except a few isolated groups, such as the Andamanese Islanders, the Kai Colos of Fiji, the Ainu of Yesso, the Fuegian Kahgans). Long isolation in new centres exposed to new conditions of life would undoubtedly tend to fix changes gradually brought about by natural causes. But, as the earth became more densely peopled, fresh shiftings necessarily arose, colonies were thrown off, contact and collision between the earliest evolved varieties became inevitable. To the influences of the surroundings were thus added the far more potent effects of crossings, and the development of fresh types and sub-varieties of all sorts proceeded at an accelerated rate. This process was necessarily continued down to the present time, resulting in ever-increasing confusion of fundamental elements, and blurring of primordial types.

To this confusion and blurring must be attributed the great difficulty now felt in determining the number and the distinctive characteristics of the original human stocks, and the amazing diversity of views that has always prevailed on this subject.

It cannot even be asserted that what we call the main divisions, the primary groups, are themselves original even in their ideal conception, and not the outcome of still more remote and earlier fusions. Who shall say that the dirty yellow tinge, for instance, of the average Chinese is not the result of a blend, as the light brown of the eastern Poly-nesi-ans certainly appears to be?

This brings us to the consideration of the so-called 'ethnical criteria'—i.e. the various factors on which ethnologists rely in their different schemes of classification. These criteria are partly internal or anatomical—the skeleton in general, and particularly the cranium; partly external—colour of skin, colour and texture of hair, and such other determining elements, whether physical or mental, as may be studied on the living subject. Although opinion varies considerably as to the value of these several characteristics, there is a general consensus in attaching special, if not permanent, importance to the three elements of colour, hair, and form of the skull. Of these colour, probably because the most conspicuous feature, was the first to be considered, and formed the basis of all the early classifications, such as those of F. Bernier (1672), who distinguished four radical types—European White, African Black, Asiatic Yellow, and Northern Lapp; of Linnaeus (1738-83), whose *homo sapiens* comprised four species—the light-skinned European, the yellow Asiatic, the black African, and brown or tawny American; and of Blumenbach (1752-1840), whose groupings fluctuated, but whose terminology (Caucasic, Mongolic, &c.) has been largely retained.

Then followed a chaotic interval, during which almost every writer proposed with equal confidence a fresh division of the primary human groups. During this period, ethnology, in common with other studies affording large scope for the exercise of the imaginative faculties, became the battleground rather of partisans than of men of science. The wildest theories on the specific unity or disparity of mankind, the permanence or evanescence of types, the innate capacity or incapacity for progress, and so forth, were advocated, often with much erudition, but little common sense, by Nott and Gliddon, Morton, Knox, even Cuvier and Agassiz, apparently more eager to further their peculiar political and religious views than to promote the cause of truth. Some of these theories were even self-destructive, as for instance those of Agassiz on unity of species and difference of origin. Most of them are now interesting only to the historian of mental aberration, and, their standpoint being mainly polemical rather than scientific, they did little to advance ethnological studies.

Order was at last restored by the craniological school, founded by the elder Retzius (1796-1860), which made the shape of the head the basis of all classification, and thus introduced exact methods into this branch of the subject. The result has shown that craniology alone cannot be depended upon to supply sufficient, or even altogether trustworthy, materials for distinguishing the main divisions of mankind. Its chief elements, such as dolichocephaly and brachycephaly (i.e. length or shortness of the skull as measured from front to back), orthognathism and prognathism (less or greater projection of the jaws), are not constant in any given groups, and in many cases the most surprising diversity prevails where some degree of uniformity it might be expected. Thus many of the Eskimos, grouped with the brachycephalic Mongol division, are marked by extreme dolichocephaly; the extinct Tasmanians, belonging to the prognathic Negro division, were highly orthognathic; no norma, either of gnathism or cephalism, can be established for the Oceanic Malay and Papuan races,

while every shade of cephalism prevails amongst the Caucasian peoples. Nevertheless, craniology can be neglected by no ethnologist, and its study has already thrown much light on various departments of anthropological science. See SKULL.

Of late years the colour and texture of the hair, the value of which had been anticipated by Linnæus, have steadily risen in the estimation of naturalists as a racial test. It is now regarded as the most constant of all the physical features, and has been made the foundation of their groupings by some of the most eminent modern anthropologists, such as Huxley, Fr. Muller, Haeckel, and Broca. Its constancy is shown by the Negro division, all branches of which, without any exception, have black and more or less woolly hair, flat or highly elliptical in section; and by the Mongol division, which, including all the American aborigines, is uniformly characterised by straight black hair of the horse-tail type, cylindrical in section. In the Caucasian division this feature varies considerably, but still within certain limits. Thus, it may be straight, wavy, or curly, but never woolly; the colour also may range from jet black through all shades of brown, and even red, to the lightest flaxen; but there still appears to be a certain correlation on the one hand between the black hair and dark complexion, on the other between the light hair and fair complexion of the two well-marked branches of the Caucasian division.

The other ethnical elements, whether physical or mental, are of little value taken apart, but are often useful aids in combination with themselves, and especially with the three above specified criteria. Such are stature; the shape, colour, and position of the eye; the weight or volume of the brain (cranial capacity); the form of the nose—remarkably constant in some groups; the form of mouth and lips; the superciliary and zygomatic arches, and all such other elements as collectively constitute the broad flat features of the lower, the oval and regular of the higher races—Kollmann's chamoproscopic and leptoproscopic types. Of mental or intellectual criteria immeasurably the most important is language, which, however, has had the misfortune of suffering from friends and foes alike, philologists rating it much too high, anthropologists depreciating it to a corresponding extent. Yet that speech cannot be neglected, even by the purely anthropological student, is obvious from the fact that different phonetic systems often involve different anatomical structure of the vocal organs. Owing to these differences, Europeans find it impossible, even after years of residence amongst the natives, to pronounce the various clicks of Bushman, Hottentot, and Zulu-Kafir tongues, or the many rasping sounds of the Thlinkit, Apache, and other American idioms. The 'absolute impossibility' of imitating certain tones in the Papuan languages of New Guinea is by Miklukho Maclay rightly attributed to 'fundamental differences in the anatomical structure of the larynx, and the whole muscular system of the organs of speech in the two races' (European and Melanesian). And he adds that 'not only the organ of speech, but also that of hearing, plays an important part, for the same word may be heard in a totally different manner by different persons' (*Ethnologische Bemerkungen*). Neither the Jews nor the African negroes in America have yet learned to correctly pronounce the European languages spoken by them as their mother-tongues for many generations. At the same time, 'philology and ethnology are not convertible terms' (Sayce), and extreme caution must always be used in the treatment of language as an ethnical test. It has too often proved a pitfall to uncritical writers.

Of other mental or moral criteria it will suffice

here to mention *religion*, which, owing to the fundamental unity of the psychic element in man, can never be regarded as a true test of race, and *social pursuits*, such as the chase, pasture, and agriculture. On the latter point much misconception prevails, and it is especially a mistake to suppose that the order of progress is necessarily from the hunting through the pastoral to the agricultural state. Some of the lowest African tribes are, and always have been, tillers of the soil, while other peoples, such as the Kirghiz and Kal-mucks, ranking much higher in the social scale, are still nomad pastors. These pursuits, in fact, are questions not of race, but of the outward conditions of soil and climate, as we see in the Arabian peninsula, where the stock-breeders of the Nejd plateau become skilful husbandmen in the Yemen uplands of the extreme south-west.

Basing their conclusions on the comparative study of all these ethnical criteria, the most eminent naturalists, from Linnæus and Blumenbach to Huxley, Virchow, Flower, Broca, and Topinard, mainly agree in classifying the whole human family in three or at most four fundamental divisions. From the foregoing exposition of the subject, it follows of itself that all classifications must be regarded not as *genetical*—i.e. divisions according to common descent—but rather as groupings according to physical and mental resemblances. It also follows that the term *fundamental* is to be understood not absolutely, but only in a relative sense; for all races (the term race being taken as practically equivalent to 'breeds' or 'varieties') are necessarily regarded as belonging to a common primeval stock, constituting a single species. At the same time it does not follow that all must necessarily be supposed to have sprung from a single human pair. On the contrary, the more natural assumption would seem to be a gradual upheaval, so to say—i.e. the slow evolution of a whole anthropoid group spread over a more or less extensive geographical area, in a warm or genial climate, where the disappearance of an original hairy coat would be rather an advantage than otherwise. This view of gradual ascent in a more or less homogeneous mass has the advantage of obviating the many difficulties connected with *unity of species* and *unity of descent*, which are now seen no longer to be identical expressions. It also allows for differences in the physical habitus *from the first*, these differences, however slight, helping in combination with altered environments to account for the divergences that have in the course of ages resulted in the present fundamental human types. Thus, we no longer require to ask ourselves, for instance, whether the black hue shaded into the yellow, the brown into the white; whether prognathism grew into orthognathism, brachycephalic or round into dolichocephalic or long heads, and so on. None of these extremes, but only the germs of all, need be assumed as starting-points; and it is not a little remarkable that the Andamanese Islanders, declared by the highest authority to be 'the most infantile' of human races, are also amongst the least marked in these respects. Their colour is dark, but far from black; their prognathism is not pronounced; their stature is low, but not dwarfish—4 feet 10 inches as compared with the Akka, 4 feet 6 inches, and Batwa, 4 feet 3 inches (Wissmann, Flower, Man). The existing marked types may therefore be taken as collateral developments rather than independent primordial conditions, or gradual modifications of any one extreme type.

The difficulty of determining the exact number of these types is due to the fact, already pointed out by Blumenbach, that none of them are found in what may be called ideal perfection, but that all

tend to merge by imperceptible degrees in each other. But the issue now appears to be narrowed down to a choice between three, four, or at most five primary groups, with one or more marked subdivisions in each. These are the black, woolly-haired *Ethiopic* (*Negro*); the yellow, lank-haired *Mongolic*; the white, smooth-haired *Caucasic*; the coppery, lank and long-haired *American*; and the brown, straight-haired *Malayo-Polynesian*. But the last is commonly rejected as evidently the outcome of comparatively recent mixture, in which the Mongolic elements predominate. In fact, the Oceanic Malays proper cannot be separated anthropologically from the Asiatic Mongol group. Most authorities also regard the American as a remote branch of the same group, and this view seems justified by the striking Mongolic features occurring in every part of the New World, as amongst the Utahs of the western States and the Botocudos of eastern Brazil. We are thus reduced to the three first-mentioned divisions, a grouping again adopted by Flower (1885), who concluded that primitive

man had in the course of ages become differentiated into 'the three extreme types represented by the Caucasian of Europe, the Mongolian of Asia, and the Ethiopian of Africa, and that all existing members of the species can be ranged around these types, or somewhere or other between them.' But it is not to be supposed that all the distinctive characters of these three types are found co-existing in any considerable masses of the several groups. The ideal *Homo Ethiopicus*, *Mongolicus*, and *Caucasicus* must therefore be constructed, so to say, by a sort of eclectic process, by selecting and grouping together the more salient features assumed to be characteristic of each. In this way has been prepared the subjoined comparative scheme of the three main divisions, the points of contrast or resemblance between which will be best shown by their juxtaposition. Here it should be noticed that the Caucasian was divided by Huxley into two distinct branches—the Xanthochroi, or fair, and the Melanochroi, or dark—which in this table are respectively indicated as 1 and 2.

TABLE OF THE CHIEF CHARACTERISTICS OF THE THREE FUNDAMENTAL HUMAN TYPES.

	Ethiopic.	Mongolic	Caucasic
COLOUR AND CHARACTER OF SKIN	Blackish, sometimes almost sooty black; velvety and cool to the touch, emitting a distinct odour.	Yellowish, passing into olive, and almost every shade of brown; rough in texture; often with a <i>fade</i> , washed-out look.	Whitish; (1) very florid or ruddy; transparent, clearly showing the veins, (2) pale, but often dusky or swarthy; both merging in some places in a light olive, in others in various shades of brown
HAIR AND BEARD.	Jet black, frizzly or 'woolly,' rather short; flat in transverse section; sometimes said to grow in separate tufts; scant or no beard.	Dull black, coarse, lank, lustreless, sometimes (in America) very long; round in section; moustache developed; beard scant or absent.	(1) Flaxen, light brown, and even red, long, wavy, and silky; (2) black or dark brown, rather straight, but sometimes kinky or curly; both oval in section; both with full beard.
SKULL AND FACE	Skull mainly dolichocephalic (long and narrow), sometimes also very high (hypsi-stenocephalic); prognathous lower jaw; high cheek-bone; large, black, round, and prominent eye, with yellowish cornea; broad flat nose; thick, everted lips, showing the red inner skin.	Skull mainly brachycephalic (round, but never quite circular); mesognathous jaw; large cheek-bone; narrow, almond-shaped, black eye, slightly oblique; very small, concave nose; features generally broad and flat, in America hatchet-shaped.	(1) Skull mainly dolichocephalic; (2) mainly brachycephalic; both orthognathous; (1) eye blue, hazel, or brown; (2) eye large, black, and bright. Both long, straight nose, often arched or aquiline; small mouth, thin lips; features mainly oval and regular.
STATURE AND FIGURE. . .	Generally tall, rather above the average, ranging from 5 feet 6 inches to 5 feet 10 inches and even 6 feet; large, bony frame, stout and robust, but weak in lower extremities.	Generally short, rather below the average, 5 feet to 5 feet 6 or 7 inches, but American branch often very tall; heavy, squat, angular frame, especially on the uplands (Tibet, Bolivia)	(1) Tall, above the average, 5 feet 6 inches to 5 feet 10 inches and 6 feet; (2) below the average, 5 feet 2 inches to 5 feet 6 or 7 inches; but much diversity within each group. (1) Powerful brawny frames, often very strong; (2) lithe, active frames, often with much staying power (Basques).
TEMPERAMENT	Sensuous, unintellectual, cheerful, and even boisterous, but fitful, passing suddenly from comedy to tragedy; hence at once affectionate and cruel; science, art, and letters undeveloped.	Sluggish, somewhat morose and taciturn; hence passive, with little initiative, but with great power of endurance, and subject at times to vehement outbursts; science slightly, art and letters moderately developed.	Highly imaginative, active and enterprising; hence at once speculative and practical; (1) somewhat solid, serious and persevering; (2) fiery, impulsive, but inconstant. Science, art, and letters highly developed in both.
LANGUAGE	All agglutinating, mostly with prefixes and alliterative harmony (Bantu); relatively few abstract terms.	Some isolating and uninflected, with tendency to monosyllabism and tone; some agglutinating, mostly with postfixes and vowel harmony; some polysynthetic; abstract terms numerous.	Nearly all inflecting, mainly by postfixes completely merged in modified root; hence more or less synthetic, with a general tendency towards analysis; abstract terms practically unlimited.
RELIGION	Non-theistic; nature-worship, with fetishism and witchcraft as conspicuous elements.	Polytheistic; spirit-worship (Animism); belief in dreams and visions (Shamanism); also higher religions.	Monotheistic (Unitarian, Trinitarian), with creeds based on revelations; priesthood (mediation) a prominent feature; also Brahmanism.

Subjoined is a brief summary of the main divisions and subdivisions of these three fundamental groups.

I. The ETHIOPIC GROUP falls naturally into a western or African, and an eastern or Oceanic division. The western, occupying all Africa from the Sahara southwards, comprises a northern or *Sudanese* branch (African Negroes proper), and a southern or *Bantu* branch (more or less mixed Negro and Negroid population), reaching north-

wards to about 5° N. lat. The former are marked by considerable physical unity and great linguistic diversity; the latter by almost absolute linguistic unity (Bantu languages) and great physical diversity. The chief members of the Sudanese branch are Mandingan, Wolof, Felup, Sonrhaj, Hausa, Egbe, Ibo, Yoruba, Fanti, Nupe, Michi Batta (West Sudan, Upper Guinea, Adamawa); Kanuri, Kanembu, Tibu, Mosgu, Yedina, Bagirmi,

Maba (Central Sudan, East Sahara, Wadai); Shilluk, Nuba, Dinka, Janghey, Bongo, Bari, Monbuttu, Zandeh (East Sudan, White Nile, and Welle-Mobanji basins); Masai, Kavirondo, Elgeyo, Samburu, Turkana (Masai Land). The chief members of the Bantu branch are Wa-Pokomo, Wa-Sambara, Wa-Chaga, Wa-Swahili, Wa-Zaramo, Wa-Sagara, Wa-Nyamezi, Wa-Gogo, Ma-Nyanja, Ma-Kua, Ma-Vita, Ajawa (eastern seaboard); Zulu-Kafir, Ba-Suto, Be-Chuana, Tonga, Ba-Rotse, Mashona, Ba-Yeye, Makalaka, Makololo, Maganya (South Africa); Ova-Herero, Ova-Mbo, Ganguella, A-Bunda, Ba-Fyot, A-Bongo, Ma-Yombe, Fan, Ba-Kale, Mpongwe, Ba-Koko, Dwalla, Bubi (western seaboard); Wa-Regga, Ba-Lolo, Tu-Shilonge, Ba-Ngala, Bu-Banghi, Ba-Teke (in the Congo and Ogowe basins).

The Oceanic division of the Ethiopic group comprises two branches: (1) The *Papuans* of the Eastern Archipelago and New Guinea; (2) the closely allied *Melanesians* of the Solomon, New Hebrides, New Caledonia, Loyalty, and Fiji archipelagos.

Within both Ethiopic domains are scattered several dwarfish groups, the so-called *Negritos* and *Negrillos*—i.e. 'Little Negroes,' perhaps representing the true aboriginal element in these regions. In Africa the best known are the *Alikas* of the Upper Welle basin, the *Obongos* of the Gabun, the *Batwas* of the Middle Congo (smallest of men). The *Bushmen* of South Africa lead through the taller *Hottentots* to the Negroes proper. In Oceania still survive the *Aetas* of the Philippine Islands, the *Simangs* of the Malay Peninsula, the so-called *Mincopies* of the Andaman Islands, and the *Arfaks* of New Guinea. The *Kalangs* of Java have recently died out. Besides their smaller stature, all the Negritos differ from the Negroes by their brachycephaly.

II. The MONGOLIC GROUP occupies the greater part of the eastern hemisphere (in Europe much assimilated to the Caucasians), and till the discovery of America was in exclusive possession of the New World. Its chief branches are: (1) The *Mongolo-Tatars* of Central and North Asia, Asia Minor, parts of Russia and the Balkan Peninsula; (2) the *Tibeto-Indo-Chinese* of Tibet, China proper, Formosa, and Indo-China; (3) the *Finn-Ugrians* of Finland, Lapland, Esthonia, Middle Volga, Ural Mountains, North Siberia, Hungary (Magyars); (4) the *Malays* and *Malayans* of the Malay Peninsula, the greater and lesser Sunda Islands, Madagascar, the Philippines, Formosa; (5) the *American Indians*, comprising all the New World aborigines.

III. The CAUCASIC GROUP has in recent times spread over the whole of the New World, South Africa, and Australasia: (1) *Nordic*, tall, fair dolichocephals: North-west Europeans, Kuids, Afghans, West Persians; (2) *Alpine*, brachycephals: Central Europeans, Armenians, Tajiks; (3) *Mediterranean*, short, dark dolichocephals: South Europeans, North Africans, Arabs, Dravidians, Polynesians, Todas, Ainu. Chieflinguistic branches: (1) *Aryans* of India, Iran, Armenia, Asia Minor, and great part of Europe, with sub-branches Hindus, Afghans, Persians, Beluchis, Armenians, Ossetians, Hellenes, Thraco-Illyrians, Italo-Siculi, Celts, Teutons, and Letto-Slavs; (2) *Semites* of Mesopotamia, Syria, Arabia, and North Africa, with sub-branches Assyrians (extinct), Syrians, Arabs, Phoenicians (extinct), Abyssinians, all except the last named now assimilated in speech to the Arabs; (3) *Hamites* of North and East Africa, with chief sub-branches Berbers of Mauritania, Tuaregs of West Sahara, Copts and Fellahin of Egypt, Fulahs (?) of West Sudan, Bejas (Bishari) and Afars (Danakil) along west side of the Red Sea, the mixed populations of Galla, Somali, and

Kaffa Lands; (4) *Basques* of the Western Pyrenees; (5) *Malayo-Polynesian* or *Austronesian*; besides many groups in the Caucasus.

The jungle tribes of the Deccan, the Veddas, the Sakai, and the Australians have been grouped as Pre-Dravidians.

Although treatises on various branches of the anthropological sciences are past counting, comprehensive works of a strictly ethnological character are not numerous, and of these few can be recommended as safe guides to the student. The subjoined are valuable either intrinsically or as able expositions of particular theories. Blumenbach, *De Generis humani varietate nativa* (3d ed. 1795); Prichard, *Natural History of Man* (1843) and *Researches* (1813); Desmoulins, *Hist. Nat. des Races Humaines* (1826); Baer, *Vorlesungen über Anthropologie* (1824); Edwards, *Des Races Humaines* (1829); Bory de Saint-Vincent, *L'Homme* (2d ed. 1827); Courtet de l'Isle, *Tableau ethnographique* (1849); Thomas Smyth, *The Unity of the Human Race* (1851); Carl Vogt, *Lectures on Man*, &c. (English ed. undated); Hollard, *De l'Homme* (1853); Cuvier, *L'Homme* (1857); Nott & Gliddon, *Types of Mankind* (1854) and *Indigenous Races of the Earth* (1854); Knox, *The Races of Men* (1862); D. Ethyl is a colourless, inflammable gas, obtained by the action of iodide of ethyl, C_2H_5I , on granulated zinc. It possesses an agreeable odour, is insoluble in water, but soluble in alcohol. It is not, however, on its own account that ethyl is of importance, but because it is the starting-point of an important series of organic compounds known as the *ethyl series*. In all of these the group CH_2-CH_3 or C_2H_5 is present, and acts as if it were an atom of some elementary substance—e.g. potassium. Thus we have

Potassium,	K;	Ethyl,	C_2H_5
A molecule of Potassium,	K_2 ;	A molecule of Ethyl,	$(C_2H_5)_2$
Potassium Iodide,	KI;	Ethyl Iodide,	C_2H_5I
Potassium Oxide,	K_2O ;	Ethyl Oxide or Ether	$(C_2H_5)_2O$
Caustic Potash,	KOH;	Ethyl Hydrate or Alcohol,	C_2H_5OH

In these we see that the group of atoms, C_2H_5 , always enters into combination as if it were indivisible, and it is usual to call this group ethyl, and to reserve the term diethyl for the compound $(C_2H_5)_2$ described above. Ethyl, C_2H_5 , is only hypothetical, and does not exist in the free state, while diethyl, $(C_2H_5)_2$, is an actual gas, called butane. See ALCOHOL, BASE, and ETHER.

Ethylamine, $NH_2C_2H_5$, is a substance resembling ordinary ammonia in its odour and many of its properties. It is found in coal-tar, in the oil obtained during the destructive distillation of bones, in the gases evolved during putrefaction, and may be produced by complicated chemical processes. It has been called an artificial alkaloid (see ALKALOID), as being ammonia in which one atom of hydrogen is replaced by the group Ethyl.

Ethylene. See OLEFIANT GAS.

Etiolation. See BLANCHING.

Etive, a salmon-river and a sea-loch of Argyllshire. The river, issuing from a loch on Rannoch Muir, near lonely Kingshouse Inn, runs 15 miles south-westward to the head of the loch, which itself extends $10\frac{1}{2}$ miles south-westward, then $8\frac{1}{2}$ westward, until at Dunstaffnage Castle, $3\frac{1}{2}$ miles NNE. of Oban, it merges in the Firth of Lorn. Narrowing from $1\frac{1}{2}$ mile to less than 2 furlongs at Connel Ferry, its reef-barred entrance, where the depth too decreases from 420 feet to 6 at low-water, this loch offers a good example of an ancient submerged glen. Like that of Loch Awe (q.v.), its scenery is magnificent, the upper reach closely engirt by mountains, of which the loftiest are Ben Cruachan (3689 feet) and Ben Starav (3541). Ardhattan Priory, founded on its north shore in 1281 for monks of the order of Vallis Caulium, is a beautiful ruin; so, too, is Dunstaffnage, the fabled seat of the Dalriadan kings, the stronghold really of Macdougals and Campbells, and the prison for a while of Flora Macdonald. See also BEREGONIUM.

Etna, or **ÆTNA** (called by the modern Sicilians MONTE GIBELLO—the last part of the name being the Arabic *Jebel* Italianised), an isolated volcanic mountain close to the east coast of Sicily, with a base 90 miles in circumference, and a height of 10,758 feet. The mountain mass rises with gentle and regular slopes up to a single cone, containing the crater, a chasm about 1000 feet in depth and from 2 to 3 miles in circumference. The regularity of the slope is, however, broken by the Val del Bove, an immense gully excavating the eastern flank of the mountain, 4 or 5 miles in diameter, and surrounded by nearly vertical precipices from 2000 to 4000 feet high; it has a singularly dreary and blasted appearance. A striking feature is the very great number of secondary cones dotted all over the flanks of the mountain. Of these the principal are the Monti Rossi, 450 feet high, twin peaks which were cast up during the eruption of 1669. The slopes of the mountain are divided into three sharply defined zones, the cultivated, the woody, and the desert region. This last, extending from about 6300 feet upwards, is a dreary waste of black lava, scorïæ, ashes, and sand, covered during the greater part of the year with a sheet of snow. The wooded region, which stretches down to the line of 2000 feet, though with considerable variation of breadth, is planted with forests of chestnuts, beeches, birches, pines, maples, and oaks. Below this lies the cultivated zone, a thickly peopled region of great fertility, where the vine, date-palm, bananas, sugar-cane, oranges, lemons, olives, figs, almonds, &c. are grown. The ascent is usually made from Catania, a town on the coast to the south. The origin of the mountain goes back to the Pliocene age, when its foundation was probably begun in a submarine bay penetrating into the west coast of Sicily. The geological structure of the Val del Bove lends support to the view that there once existed a second great crater, the centre of permanent eruption.

The most remarkable of the recorded eruptions of Etna are the following: 1169, when Catania and 15,000 of its inhabitants were destroyed; 1329, when a new crater opened near the Val del Bove; 1444, when the cone fell into the crater; 1537, on which occasion two villages and many human beings perished; from 1603 to 1620 Etna was almost continually in activity; in 1666 three new craters were formed. The most violent outburst of all was, however, that of 1669, when a chasm 12 miles long opened in the flank of the mountain, and from it issued a line of flames, whilst a new crater was made. During an outburst in 1755 a large flood of water was poured down from the Val del Bove. In 1852-53 there was a violent eruption which lasted nine months; a

torrent of lava, 6 miles long by 2 broad, and some 12 feet in depth, was ejected. There were great eruptions in 1879, 1886, 1892, and 1923. In the last mentioned the new crater of 1911 (on the north-east side of the main cone) was active, and a lower crater sent forth a lava-flow that reached the outskirts of Linguaglossa. About 100 eruptions have been pretty accurately described, 16 having occurred in the 19th century. In 1880 an observatory was built on the south side of the mountain, at a height of 9075 feet above the sea (nearly 1000 feet higher than the hospice of the Great St Bernard). See Feirara, *Descrizione dell'Etna* (1818); Rodwell, *Etna and its Eruptions* (1878); Sartorius von Waltershausen, *Der Aetna*, edited by Von Lasaulx (2 vols. Leip. 1880); G. de Lorenzo, *L'Etna* (1907); *Geographical Review* (1916).

Eton, a town in the south of Buckinghamshire, on the left bank of the Thames, 21 miles WSW. of London. It lies opposite to Windsor, in Berkshire. Eton chiefly consists of one long street, and is mainly dependent on the college. Pop. 3000.

ETON COLLEGE, one among the most famous educational establishments in England, was founded in 1440 by Henry VI., under the title of 'The College of the Blessed Mary of Eton beside Windsor.' The original foundation consisted of a provost, 10 priests, 4 clerks, 6 choiristers, 25 poor grammar-scholars, a master, and 25 poor infirm men. The king provided for the establishment out of his own demesne lands and the estates of certain alien priories. A supplementary charter was granted in 1441, in which year also the college buildings were commenced. Henry was very solicitous that the work should be of a durable kind. Some of the buildings were finished in 1443, and were handed over by the royal commissioners to the provost, clerk, and scholars. Political troubles of various kinds retarded the completion of the buildings till 1523. Bishop Waynflete was the first head-master, and afterwards a munificent supporter of the college. The institution passed through much peril in the reign of Edward IV., and again in the time of the Commonwealth; but it weathered the dangers, and the increasing value of its estates brought in a large income. Since 1868 the college consists of a provost and 10 fellows, who constitute the 'governing body,' 2 chaplains or conductors, and 70 king's scholars or collegers. The members of the governing body are nominated by the universities of Oxford and Cambridge and other learned and responsible electors. The scholars are lodged within the college walls. The main portion of the establishment, however, consists of the *oppidans*, students who live in houses held by the masters, and whose friends pay liberally for their education. The tuition is the same for them as for the collegers. There are valuable scholarships at King's College, Cambridge, also other scholarships and prizes open to all. Till 1851 the course of education was purely classical, but mathematics was admitted into the curriculum in that year, physical science in 1869, and the college now possesses an admirable museum, laboratory, and observatory. Among famous Etonians have been Bolingbroke, Boyle, Canning, Chatham, Lord Randolph Churchill, Derby, Fielding, Fox, Gladstone, Gray, Hallam, Kinglake, Lyttelton, Milman, Porson, Praed, Pusey, Lord Rosebery, Lord Salisbury, Shelley, Fitzjames Stephen, Leslie Stephen, Swinburne, the Walpoles, Wellesley, and Wellington. Famous heads have been Lupton, Udall, Savile, Wotton, Barnard, Keate, Hawtreys.

The college buildings are of various date and varying beauty—from the original work of the 'royal saint' onwards—include the chapel (with remarkably fine mural paintings by William Baker,

1479-1488), hall, library, and schools, the provost's and master's apartments, and the lodgings of the fellows, surrounding two quadrangles. The chapel is of stone, the other buildings of brick; and the effect of the whole is strikingly picturesque, as seen from the terrace of Windsor Castle. The Gothic chapel is especially beautiful, rich in carving and painted glass. The 'Montem,' or triennial procession to Salt Hill (*ad montem*), was celebrated last in 1846. The acting of miracle plays on Founder's Day was revived in 1919.

Étretat, a Norman watering-place, 18 miles NE. of Havre; pop. 2000.

Etruria, the country of the Etruscans, lay west of the Tiber and the Apennines, and included the valley of the Arno. In the 6th and 5th centuries B.C. the Etruscans held also the valley of the Po, called Etruria Circumpadana, and a region south of the Tiber, called Etruria Campaniana. Etruria Propria was a confederation of twelve cities or states, the *duodecim populi Etruriae*. No list of these cities has come down to us, but Veii, Tarquinii, Caere, Clusium, Cortona, Perugia, Vulci, Volsinii, Vetulonia, Volaterræ, and Arretium may probably be included, while the twelfth may have been either Rusellæ, Falerii, or Populonia. To the northern confederation twelve cities are also assigned; among them we may reckon Mantua, Chiavenna, Felsina (Bologna), Ravenna, and Hatria, important enough to give a name to the Adriatic. In the southern province were Capua and Nola, and possibly Salerno. Some of these cities are now deserted sites, marked only by vast cemeteries and the remains of cyclopean walls, while others still retain more or less of their old importance.

Veii, for four centuries the formidable foe and rival of Rome, from which it is only 11 miles distant, is now utterly desolate. It was taken and destroyed by Camillus in 396 B.C. The necropolis, extending over 16 sq. m., attests the splendour of the ancient city and the vast population which must have dwelt within its walls, 7 miles in circuit. Six miles from the sea, midway between Rome and Civita Vecchia, is the village of Cervetri, which preserves the name and marks the site of Caere, which, under its older name of Agylla, is said to have been a 'Pelasgian' city before the arrival of the Etruscans. On this site inscriptions have been found, written in a language and an alphabet called 'Pelagic,' and believed to be pre-Etruscan. The paintings in some of the tombs are in a style no less archaic. Of later date is the tomb of the Tarquins, who are said to have fled to Caere when expelled from Rome. Cortona, perched upon a rock, and surrounded by fragments of massive walls, possibly of pre-Etruscan date, occupies the most venerable site in Italy. In the time of Herodotus, Cortona, like Caere, retained its 'Pelagic' character. Dionysius says it was a great and flourishing city of the Umbrians before it was taken by the Etruscans, who made it their northern capital. The bronze-workers of Cortona were renowned, and the local museum contains noteworthy examples of their skill. The southern capital was Tarquinii, a city purely Etruscan. Corneto, a town 60 miles from Rome, and not far from the sea, occupies a portion of the site. The necropolis of Tarquinii, which extends over many miles, contains several sepulchral chambers, painted in the archaic style of the genuine art of the Etruscans, and giving a curious insight into

their religious beliefs. We have scenes from the under-world, representing souls riding on horseback or seated in cars, led away in the charge of good or evil spirits. Elsewhere the daily life of the people is depicted; we see horsemen returning from the chase, chariots, boar-hunts, wrestlers, pugilists, banqueting scenes, dancing girls, and musicians. Fig. 1 represents a dancing girl and musicians from the walls of a tomb called the Grotta del Trinculino, and fig. 2 a death-scene from a tomb called the Camera del Monte. The tombs of Clusium (now Chiusi) exhibit the same archaic character as those of Tarquinii. A vast chambered tumulus called the Poggio Gajella may be that described by Varro as the tomb of Lars Porseua. Vulci, though barely mentioned by historians, must have been a very wealthy and populous city. The necropolis has yielded in plenty some of the richest artistic treasures of any Etruscan site. The Cucumella, a huge chambered tumulus like that at Clusium, bears a curious resemblance to the great tomb of Alyattes, king of Lydia, the father of Croesus, near Sardis. Volsinii (Orvieto) was one of the most powerful Etruscan cities, and one of the last to yield to Rome. Here have been found many painted vases, and at the foot of the hill to the north lies a great Etruscan cemetery. Perugia (Perugia) is peculiarly rich in inscriptions, among them the famous cippus (46 lines). It has not been deciphered, but appears to be the record of the assignment of a sepulchre to the Velthina family. Velathri (now Volterra), called Volaterræ by the Romans, stands, like Cortona, upon an almost impregnable rock, surrounded by Etruscan walls, five miles in circuit. It held out against the Romans after all the rest of Etruria had been subdued. The people burned their dead instead of burying them, and the local museum contains many ash-chests, like miniature sarcophagi, the sides carved with mythological subjects, or with representations of bull-fights, boar-hunts, horse-races, and gladiatorial combats. Cyclopean walls mark the sites of Rusellæ, Cosa, Saturnia, and of Pupluna (Populonia), a seaport, interesting chiefly for its coins. The walls of Fiesulæ (Fiesole), near Florence, are well known to travellers. Vetulonia was formerly identified with Magliano, but now with Colonna (Vetulonia since 1887) in the Maremma; here an extensive necropolis has yielded many objects of archaeological value. Neither Luna nor Pisa has yielded any remains of interest. Other Etruscan sites, among them Viterbo (Surrina), Bologna (Felsina), Toscanella (Tuscania), Siena (Senæ), Arezzo (Arretium), Sovana (Suana), Falerii (Faleria), and Ferento (Ferentum), are described by Dennis, *Cities and Cemeteries of Etruria* (2d ed. 1878), to which the reader may be referred for fuller information.

History.—The history of Etruria, like that of Carthage, has to be reconstructed from accounts transmitted by hereditary foes. The Roman legends represent Etruria as a powerful and wealthy state before Rome was founded. According to a tradition preserved by Varro, the Etruscan era commenced in 1044 B.C., nearly three centuries before that of Rome. When legend ceases and history begins, we find the Etruscans a great naval power, allied with Carthage against the Greeks, and dominant throughout northern and central Italy, Rome itself being included in the Etruscan dominion, and ruled by Etruscan kings. The legend of the migration of the Tarquin dynasty from Tarquinii may signify the extension of the domination of that powerful city over the regions southward of the Tiber. A cemetery, believed to be Etruscan, has been discovered on the Esquiline, and the Cælian Hill in Rome bears the name of the Etruscan chieftain Cæles Vibenna. The

paintings and inscriptions in a tomb at Vulci give an Etruscan version of the Tarquinian story. We see the hero 'Macstrna' (Mastarna), an Etruscan appellation applied to Servius Tullius, cutting the bonds of his friend and companion Caille Vibinas (Cæles Vibenna), while Cneve Tarchunies Rumach (Cn. Tarquinius Romanus) is being killed by an Etruscan. The names of Tarquin, Mastarna, and Cæles Vibenna, thus curiously preserved, prove that Livy's account of the Etruscan kings of Rome is not wholly legendary. But that it was not derived from contemporary sources is indicated by an archaeological discovery of much interest. We learn that in 509 B.C. Lars Porsena of Clusium, as Livy calls him, marched with a great army to the gates of Rome to re-establish Tarquin on the throne. Now, in a tomb at Vulci, a sarcophagus was found, on which is depicted in relief a high official with insignia resembling those of a Roman consul. He is riding in procession on a biga, preceded by two lictors with their fasces, and followed by two servants. The inscription informs us that this deceased magistrate, Tute Larth, was *pursvanc thuns*, 'five times Porsena.' It is manifest that Porsena was not, as Livy supposed, a proper name, but, like 'Pharaoh' in Egypt, the designation of an office; and that the Etruscan chief who took up Tarquin's cause was the elected 'Porsena' or chief-magistrate of Clusium. In like manner, since the word *machs* meant 'first' in Etruscan, it seems probable that Macstrna, the Etruscan appellation of Servius Tullius, was not a proper name, but a designation of the kingly office, equivalent, it would seem, to Princeps. We are also told that Tarquin, with his two sons, Titus and Aruns, took refuge in Cære. Not only are Tite and Arnth usual names in Etruscan epitaphs, but at Cervetri, the site of Cære, there is an immense chambered tomb containing mortuary records of forty-six members of the Tarca family, which must have been resident at Cære for many generations.

As an Etruscan city, Rome plainly attained a greater height of prosperity than she regained for

circus, the gladiatorial combats, the horse-races, the triumphal processions, the pipe-players, the lituus, the colleges of augurs, as well as the arrangement of the house, the art of constructing aqueducts and sewers, the division of the *as* into twelve parts, the beginnings of military science, and some of the Roman weapons. More than all, the high position of the wife, so different from that which she occupied in Greece, was the same as that which she occupied in Etruria.

How feeble was the Roman republic in its

Fig. 1.

infancy appears from the fact that for a century after the expulsion of her Etruscan lords Rome maintained with varying fortunes the struggle with the Etruscan town of Veii, distant 11 miles only from her gates. That Veii fully held her own is shown by the admission that in the year 476 B.C. she captured the Janiculum. At that time the Etruscans were still the greatest military power in Italy. At the height of their prosperity, in the 6th century B.C., they shared with the Phœnicians and the Greeks the maritime supremacy of the Mediterranean. In 538 B.C., in conjunction with the Carthaginians, they sent a powerful fleet to expel the Greek colonists from Corsica. They attacked the Greek colony of Cumæ in 525 B.C., and again in 474 B.C., when their naval power was shattered by Hiero I. of Syracuse, in a great battle fought off Cumæ, the first event in Etruscan history as to which we possess contemporary records. The victory was celebrated by an ode of Pindar, then resident at the court of Hiero; while from the inscription on a bronze helmet, found at Olympia in 1817, and now in the British Museum, we learn that it was an Etruscan trophy from Cumæ, dedicated by Hiero and the Syracusans to the Olympian Zeus. In 453 B.C. we find the Etruscans still in possession of Corsica, and in 414 they were able to send a contingent of three ships to aid the Athenians at the siege of Syracuse.

But from this time dates the rapid declension of their power. Towards the close of this century the Etruscan dominion in Campania was overthrown by the Samnites and the Greeks of Cumæ, Capua being taken by the Samnites in 423. Then the Gauls swarmed over the Alps, and, after overwhelming the Etruscan cities in the valley of the Po, crossed the Apennines, having destroyed the wealthy city of Melpum in 396 B.C., the year in which the long struggle between Rome and Veii was brought to an end by the capture of the latter by Camillus, after a ten years' siege. The Gauls continued their devastating progress through Etruria, and in 390 plundered Rome, after having vainly laid siege to Clusium. Etruria was fatally weakened by the loss of her two outlying provinces and the devastation of the central province by the Gauls. After a prolonged resistance, southern Etruria submitted to Rome in 351 B.C. In 311 war was renewed; the Romans crossed the natural boundary formed by

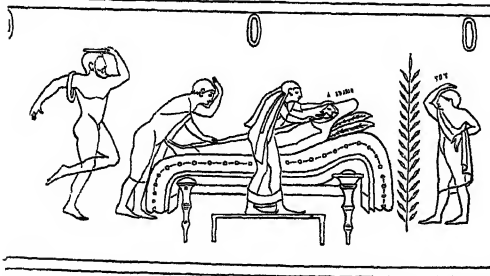

Fig. 2.

two centuries. This is indicated not only by the legends of the splendour of the Tarquinian kings, but by the evidence of such vast constructions as the Cloaca Maxima, the Capitoline temple, and the Servian wall. The state ceremonial of Rome appears also to have descended from the period of Etruscan rule. The insignia of consular authority, the toga prætexta with its purple border, the ivory curule chair, the twelve lictors with their fasces and axes, all of Etruscan origin, are not likely to have been copied from the usages of hereditary foes, but are more probably survivals from the period when Rome was one of the Etruscan cities. An Etruscan origin may also be assigned to the

the Ciminian Forest, and, after repeated defeats of the Etruscans, a decisive contest took place in 283 at the Vadimonian Lake, when Tarquinius lost its independence; and three years later the Romans reached Volaterræ, the northern stronghold of the Etruscans, when the struggle, which had endured for five centuries, came finally to an end.

In the Second Punic War, the chief Etruscan cities furnished supplies for the Roman fleet. It is plain that these cities retained wealth and power as semi-independent allies under the Roman suzerainty. They seem to have been gradually Romanised, and were finally admitted to the Roman franchise in 89 B.C. The great Etruscan families secured leading positions in the Roman commonwealth. Pompey the Great seems to have been of Etruscan lineage, tombs of the Puppi family having been discovered at Corneto (Tarquini), Clusium, Cortona, and Perugia. There was a Tarquinian gens at Rome in the time of Cicero, while Mæcenas, who bears an Etruscan name, was from the Etruscan city of Arretium (Arezzo). Families of undoubted Etruscan lineage still linger on in Etruria. The necropolis at Volterra contains the tomb, with Etruscan epitaphs, of the Cæcina (Cæcina) family, members of which distinguished themselves under the early emperors, and whose lineal representative, Nicolas Cæcina, bishop and patrician, was buried in the cathedral of Volterra in 1765.

Origin.—The people of Etruria were called Etrusci or Tursci by the Romans, Tyrrheni or Tyrseni by the Greeks, Tursci by the Umbrians, and Rasena by themselves. Their origin and ethnic affinities though much discussed are still in doubt. An early tradition, reported by Herodotus, and often repeated, brings them from Lydia; but Dionysius of Halicarnassus doubts any such migration, because it is not mentioned in the Lydian history of Xanthus, and because the Etruscans differed from the Lydians in language, laws, customs, and religion. Dionysius says the Etruscans were unlike all others in speech and manners, and claims for them an indigenous origin.

Modern writers who accept the Lydian tradition point out that Tarquinius, probably the mother-city of the Etruscans, is near the coast, that striking structural resemblances exist between tombs at Vulci, Clusium, and Tarquini and certain tombs near Sardis, that certain Lydian inscriptions seem to contain some of the Etruscan symbols. They argue, too, that if Phœceans settled in Corsica, Lydians may have found their way to Italy. It must be acknowledged, however, that the migration of so numerous a people by sea is a formidable difficulty.

The difficulty is of course overcome by those who hold that the Etruscans entered Italy by land-route from the north; but here it should be remarked that the general tendency of archaeological research is to discredit the view that the Etruscans were invaders from the Rætian Alps. That the origin of the Etruscans should have been referred at various times to such diverse peoples as the Egyptians, Phœnicians, Hittites, Babylonians, Ligurians, Celts, Basques, Finns, serves well to prove the complexity of the problem. Perhaps the theory which now gains most general acceptance is that probably there were two elements in the population of Etruria, one autochthonous, numerous, and servile; the other an intrusive conquering aristocracy, Pelasgian in stock, and coming to Italy by sea-route from the east. Thus Cære and Cortona are said to have been 'Pelasgic' cities before they became Etruscan. Certain inscriptions from Etrurian tombs, formerly classed as Etruscan, are now attributed to the more ancient 'Pelasgic' race. Conestabile dis-

tinguishes between the tombs of an aboriginal people who practised cremation and those of the later invaders who buried their dead. Livy says that the speech of the country-folk in Etruria differed from the language spoken in the towns, and we may well believe that a conquered race would be left to till the soil for the benefit of invaders dwelling in walled towns. The splendid tombs from which our knowledge of Etruscan speech, luxury, and art is derived cluster round the walls of a few great cities, and are mostly the sepulchres of wealthy nobles. We occasionally meet with the urn of a freedman (*lautni*) or of a slave, but we know nothing of the tombs of the inhabitants of the villages, who may well have belonged to another race, and have spoken a different language. Again, the abrupt collapse of the Etruscan dominion in Campania and in the valley of the Po indicates that it was a dominion of conquest rather than of colonisation, and the complete effacement of the language in Etruria proper argues that the Rasena were a ruling aristocracy, comparatively few in number, though high in culture.

The physical type of the Etruscans is hardly to be determined from the evidence of the crania of their tombs; for while heads are to be found there which represent the intruding Aryan, so also are skulls which, if they represent the intruding Etruscan, are certainly indistinguishable from the crania of the native Ligurians (Italians). The descriptions by ancient authors, '*pinguis Etruscus*,' '*obesus Tyrrhænus*,' are confirmed by the recumbent portrait effigies on the sarcophagi, which show the Etruscans as a sturdy race, short and stout, with large heads, thick arms, high colour, scanty beard, and hair black or occasionally chestnut. It has been remarked that they were not unlike the Kheta (Hittites) who invaded Syria from the north, and whose monuments are found in Asia Minor as far west as the neighbourhood of Sardis. In any case we may agree with Dionysius that the language, customs, and religion of the Etruscans differed from those of any nation with which he could have been acquainted, while their physical type, as represented on their monuments, is so unlike that of other Europeans as to incline us to agree with the dictum of Seneca: *Tuscos Asia sibi vindicat*—'Asia claims the Etruscans as her own.'

Language.—The Etruscans had an extensive literature. The subjects represented on the monuments prove their familiarity with the tale of Troy and the cycle of Greek heroic legend, and we learn that they possessed histories, poems, dramas, and works on augury and divination. A fragment of writing (now in the museum of Agram), identified as part of a Book of Ritual, was found in 1891 on a piece of linen wrapped round an Egyptian mummy, but with this exception all their books have perished, so that in addition to a few doubtful Etruscan words preserved by Hesychius, Vairo, and other writers, our knowledge of the language is derived almost solely from inscriptions. Of these inscriptions some thousands have been discovered, but we have unfortunately no clue to their meaning, as the few bilinguals consist mainly of proper names. It is in these circumstances that it has so far been found impossible definitely to connect the Etruscan tongue with any of the known great families of language. Thus in modern times it has been maintained that the Etruscan language was Semitic, Celtic, Armenian, Gothic, Basque, or Albanian. Professor Sayce thinks it is *sui generis*, belonging to a family of speech which has everywhere become extinct. Many hold that the affinities are Ugro-Altaic, while the reference to Asia Minor has also gained ground. The failure of Corssen's attempt to explain the language as an Aryan dialect, akin to Umbrian, Oscan, and Latin,

was a gain in the negative direction, and few scholars would now be found to maintain that it belongs either to the Aryan or Semitic family of speech. It seems rather to have been an agglutinative dialect, approximating, like Finnic, to the inflectional stage. It was written from right to left, in an archaic form of the Italic alphabet, which was obtained from Euboea about the 7th century B.C. In retaining the letters *theta*, *phi*, *chi*, and *san*, and in rejecting *d*, *b*, *g*, and *o*, the Etruscan alphabet differs from the Latin.

Most Etruscan inscriptions are very short, few containing more than twenty words. A sepulchral tablet of Capua and the Perugian cippus mentioned above bear the only two of length. Inscriptions have been found as far north as the Alps, near Nice, Turin, and the lakes of Como and Lugano. But they come mostly from Central Etruria. Some vast cemeteries, such as those of Veii and Bologna, have yielded few or none, possibly because they date from a time when the art of writing had not become general.

The greater part of the inscriptions are short mortuary records, stating usually the name and parentage of the deceased; his age, his condition in life, and the public offices he held being occasionally added. They occur on the walls or over the entrances of vaults, on steles or pillars erected in front of tombs, or on the labels and seals of sepulchral niches, but they are more usually painted on the urns, or cut in the stone of the sarcophagi, a recumbent figure of the deceased frequently reposing on the lid, while the sides are sculptured with mythological subjects or scenes from the life of the deceased. The inscriptions found in 1886 in Lemnos in a language resembling Etruscan have been important, not so much linguistically as from the point of view of racial origins.

Working with such materials, considerable progress has been made in the decipherment of the language. True, the leaf of the Book of Ritual, the sepulchral tablet of Capua, and the cippus of Perugia have been only very partially interpreted, but in the decipherment of the language most of the short mortuary inscriptions can now be read with tolerable certainty. To the small vocabulary new words continue to be added. Of proper names a few, such as Caie (Gaius), Cneve (Gnaevus), Marce (Marcus), and Tite (Titus), are borrowed from neighbouring or subject races. Of genuine Etruscan names the most usual for men are Arnth (Aruns), Aule (Aulus), Larth (Lars), Sethre, Veie, Velthur, and Vete; and for women, Arnthia, Aulia, Larthia, Sethria, Fastia, Ramtha, Thania, and Thanevil. Many Roman gentile names, such as Spuriina and Perpena, were of Etruscan origin, while Pompeius, Petronius, Cafatius, Cassius, Cæcina, Volumnius, and Afinius appear in Etruscan tombs as Pumpu, Petrui, Cahate, Cazni, Ceicna, Velimna, and Afuna. A few Etruscan names have been explained. Thus, Thanevil (Tanaquil) was the wife of Tarquinius Priscus. Thana must have been the Etruscan goddess of maternity (= Juno Lucina), as on a mirror she assists at the birth of Minerva, and *cvil* (or *ever*) denotes 'gift' or 'dedication,' the word Tinsvil being inscribed on objects dedicated to Tinia (Jupiter). Hence Thanevil would mean 'Thana's gift,' and may be compared with such Christian names as Theodore or Diodorus. Again, Spurie, an Etruscan name, seems to be equivalent to the Latin Publius. The words *spural* and *spurana*, inscribed on vessels, armour, and tombs, signify that they were 'civic' or 'public' property; and the phrase *amce marunuch spurana*, in an epitaph, probably means '*fuit curator publicus*.'

Relationship is sometimes expressed by words, such as *puia*, 'wife'; *clam*, 'son'; *sec*, 'daughter'; but more commonly by suffixes. Thus, Aulesa is

the 'wife of Aule,' Theprisa the 'wife of the Thepri' (Tiberius), Larthial the 'son of Larthia,' Larthialisa the 'wife of Larthia's son.' Velthur is a 'descendant of Veie,' and Velthurithura a 'descendant of Velthur.' Gentile names are formed by the suffix *-na*, corresponding to the Latin *-nus*. Thus, Vipna is the equivalent of Vibius, Varna of Varius, Caizna of Cæsius. This suffix is a common formative. Thus *suthi*, 'sepulcrum,' gives *suthuna*, 'sepulchralis.' The suffix *-l oi* *-al* has a similar force—e.g. *fufun l*, 'a Bacchic cup,' from *Fufuns*, 'Bacchus'; and *Trunal*, 'a Trojan,' from *Truia*, 'Troy.' Other ethnic formatives are *-ach* and *-ate*, as *Rumach*, 'a Roman,' and *Mantivate*, 'a Mantuan.'

Six words inscribed on the faces of a pair of dice give the first six digits, and other numerals appear in records of age which occur in epitaphs. The words *mach*, *ci*, *zal*, *sa*, *thu*, *huth*, *semph*, *cezp*, *mur* are believed to be the digits, while *ce-alchl*, *cezp-alchl*, *semph-alchl*, *muw-alchl*, *zathrum*, and *ciem-zathrum* must be decades. Ordinals and multiplicatives are formed from the cardinals. Thus *ci*, 'two,' gives *ci-s*, 'second,' and *ci-zi*, 'twice.'

The detection of the numerals has made it possible to show that the plural ends in *r* or *l*. Thus, *clan*, 'son,' gives *clen-ar*, 'sons'; as *ci clenar*, 'two sons,' and *clenar zal*, 'three sons.' The phrases *huth naper*, *naper ci*, *naper xii*, show that *naper* is a plural, meaning 'loculi' or 'tombs.' The plural in *-l* also appears in *arce ril lavu*, 'habuit annos lavu,' and in *mursl xz*. So *tular* signifies 'cippi,' and *suthinesl* 'sepulchral niches.'

The names of men and women already cited, and such forms as *lautni*, 'a freedman,' and *lautnatha*, 'a freed-woman,' show that Etruscan was a gender language. There seems to have been no distinction between nominative and accusative. The genitive ended in *-s*, the dative in *-si* or *-thi*; and, as in the Altaic languages, the plural suffix preceded that denoting the case. Thus, from *clan*, 'son,' we have gen. *clen-s*, dat. *clen-si*, nom. and acc. pl. *clen-ar*, dat. pl. *clen-ar-as*; while *precuth-ar-as* is the dat. pl. of *precus*. From *tiv*, 'moon' or 'month,' we have *tiv-r*, 'menses,' and *tiv-r-s*, 'menstrum'; from *usil*, 'sol,' *usil*, 'solis'; and from *suthi*, 'sepulcrum,' *suthi-thi*, 'sepulchro.' The suffixes *-c* and *-m* are enclitic conjunctions—thus, *vel. sethre puia* is the epitaph of 'Veie Sethre and wife,' and *arnth vipis serturis puia mutainei* that of 'Arnth (son of) Vipi Serturi and (his) wife Mutainei.' According to Dr Pauli, *mi* means 'this,' or 'this is,' while *cehen*, *cen*, or *ecn* means 'here.' The meaning of several substantives, in addition to those already cited, has also been determined with tolerable certainty.

Coming to the verbs, *am-ce* certainly means '*fuit*,' while *ma* appears to be '*est*.' The 3d pers. sing. of the perfect tense ended in *-ce*, and of the present in *-e*. We have *tur-e*, 'dat'; *tur-ce*, 'dedit'; *ar-ce*, 'habuit'; *tham-ce*, 'extraxit'; *sval-ce*, 'obit'; *lupr-ce*, 'decessit.' Thus, *clenar zal arce* is '*filios tres habuit*,' and *ramtha matulnei sech marces matulnas puia* *amce sethres ceisinies* may be translated 'Ramtha Matulnei was the daughter of Marce Matulna, and wife of Sethre Ceisinie.' These examples may serve to show that the once apparently hopeless task of translating the Etruscan inscriptions is at last in a fair way of being accomplished.

Religion.—The Etruscans were proverbially a religious people—'*gens ante omnes dedita religionibus*'—'*genitrix et mater superstitionis Etruria*.' Their tombs bear witness to a belief in a future life, and a dread of the malignant power of their deities. Affairs of state were regulated by the decisions of colleges of haruspices and augurs, who interpreted, according to established rules, omens and portents obtained from the inspection of the

entrails of victims, the flight of birds, and from lightning, of which twelve kinds were distinguished. Varro, Cicero, and Martianus Capella have described the methods of divination, as laid down in the *libri discipline Etruscae*. The heavens were regarded as the *templum* of the gods, and were divided into sixteen regions, in each of which one or more of the gods presided or resided. By ascertaining the precise 'region' in which an omen, such as a flash of lightning, occurred, the fulgurators determined the name of the god who sent the message, and interpreted it in accordance with his functions. Those gods who possessed the power of sending lightning were called the Novensiles, or 'Thunderers.' In the museum at Volterra is an effigy of an augur, holding in his hand the instrument by which these observations were made, and a real specimen of the instrument has actually been discovered near Piacenza. It is a bronze model of the liver of a calf, which must have been used like a sextant. Beginning with the north, the rim is divided into sixteen compartments, in each of which the name of one of the gods is engraved. The heavens were observed through apertures which correspond to the blood-vessels which supply the liver. One side of the instrument is dedicated to the sun, the other to the moon, probably for observations by day or by night. The protuberance called the *lobus Spigellii* was the 'mount of the gods,' and the gall-bladder was dedicated to Neptune. The names of the deities inscribed on this curious instrument, coupled with the account of Martianus Capella, have supplied unexpected information as to the Etruscan Pantheon, and this is supplemented by the names appended to the deities in the mythological subjects painted on the walls of tombs, or engraved on the backs of those polished bronze mirrors of Etruscan ladies, so many of which have come to light. In many cases the subjects are taken from the Greek mythology, and the names are merely those of Hellenic or Italic deities, conformed to the phonetic laws of Etruscan spelling. Such are Ani (Janus), Uni (Juno), Maiis (Mars), Apulu (Apollo), Nethuns (Neptune), Erle (Hercules), Meniva (Minerva), Velch (Vulcan), Satre (Saturnus), Artumes (Artemis), Letun (Latona), Vetis (Vedius), Silvans (Silvanus), Aita (Hades), Phersipnei (Persephone), and Charu (Charon). But besides these borrowed names, there are a host of genuine Etruscan deities, such as Tinia, who answers to Jupiter, Laran to Mars, Fufuns to Bacchus, Sethlans to Vulcan, Turan to Venus, Tuims to Mercury, Thalna to Juno, Thana to Lucina, Thesan to Aurora, while the sun and the moon were called Usil and Lala. Of other deities no analogues have been found in the Greek or Roman Pantheon. Lasa and Mean seem to be recording Fates; Epiur, Snenath, Munthuch, and Malavisch to be guardian spirits; Tuchulcha, Asira, Nathum, and Tarsu avenging Furies; Vanth, Leinth, and Culsu con-

ductors of souls or deities of the tomb. More obscure are the functions of beings called Racuneta, Talitha, Tethum, Thufia, Mlacuch, Achuvitr, Tipanu, Sitmica, and Ethausva. If anything were wanted to prove that the Etruscan mythology differed from that of all Aryan, Semitic, and Hamitic nations, this strange list of names would be sufficient. Classical writers have assigned to the Etruscans other deities whose names are not found in inscriptions, and which may be Sabine, Umbrian, or Faliscan. Among them may be enumerated Mantus and Mania, king and queen of the under-world; Summanus, a god who ruled the night; Vertumnus, the god of autumn; Voltumna, whose temple was the meeting-place of the federated states; Nortia, the goddess of Fortune, in the doors of whose temple at Volsinii nails were

Fig. 3.—Etruscan Mirror from Vulci, with Fufuns (Bacchus), Semla (Semele), and Apulu (Apollo).

Half size. After a Drawing by Mr George Scharf.

driven to mark the successive years; and the Novensiles, a collective name for those gods who hurled thunderbolts.

Civilisation — The government was a loose federal union of the twelve cities or states, each ruled by magistrates annually elected from a class of hereditary sacerdotal nobles. The titles of these magistrates, Lauchme (Lucumo), Purtsvana (Porsena), and Marunuch, probably correspond to Consul, Imperator, and Cuiator. The position of the wife was high; she is the social equal of the husband, she takes her place at the feast, her tomb is sumptuously furnished, and descent through the mother is recorded even more uniformly than through the father. The reliefs on the Afuna sarcophagus at Palermo, in which a matron bids farewell to her sorrowing family, afford a touching proof of the affection with which the wife and mother was

regarded. Of the high civilisation attained by the Etruscans we have abundant proofs. Till the battle of Cumæ they were one of the three great naval powers of the Mediterranean. They excelled in medicine, astronomy, mining, metallurgy, and such engineering works as the construction of roads, tunnels, and chambered tombs. The walls of their cities, built of huge blocks, admirably fitted together without cement, remain to attest the skill of the artificers. The jewelry, of the Phœnician type, with patterns formed by soldering on minute grains of gold, is unrivalled. The skill of the bronze-workers is shown by the Chimæra and the statue of the Orator at Florence, by the Wolf in the Capitol at Rome, and by a magnificent lamp at Cortona. The earlier coins, which date from the 6th century B.C., show the influence of Asia Minor, while after the repulse of the Athenians in Sicily they are modelled on the coinage of Syracuse.

Many of the painted vases which have been found in such vast numbers in Etruscan tombs were either imported from Greece or made by Corinthian artists who had settled in Etruria, the subjects represented being drawn mainly from Greek mythology or the cycle of Homeric legend. Some of these vases may have been prizes won in the national games, and deposited in the tombs as cherished possessions of the deceased, together with his armour and his weapons. In like manner, the polished mirrors and jewelry of Etruscan ladies were commonly placed in their tombs. But the tombs are themselves the most characteristic works which the Etruscans have left behind them. They are of two kinds: the stone pyramid or cone with interior chambers, which is manifestly a survival of the tumulus, and the rock-cut chamber, which is a survival of the cave. But Etruscan tombs are not merely sepulchres; they are abodes for the spirits of the dead, constructed on the model of the abodes inhabited during life; they are provided with chairs and other furniture; useful and ornamental objects were deposited by the body of the deceased, while the walls were decorated with subjects from daily life, or scenes from the under-world. There is usually an antechamber in which the family could assemble at the annual funeral feast to do homage to the spirits of departed ancestors.

The best general work still is *Die Etrusker*, by K. O. Müller, edited by Dr Deecke (1877), supplemented by Deecke's *Etruskische Forschungen* and Pauli's *Etruskische Studien*. For inscriptions, see Fabretti, *Corpus Inscriptionum Italicarum*, Pauli, *Corpus Inscriptionum Etruscarum* (1893-1902); for tombs, Dennis, *Cities and Cemeteries of Etruria*, for mirrors, Gerhard's *Etruskische Spiegel*. See also Jules Martha, *L'Art Étrusque* (1888), and La Langue Étrusque (1913); Thomsen, *De la Langue Étrusque* (1899); Ridgeway, *The Early Age of Greece* (1901); Cameron, *Old Etruria and Modern Tuscany* (1909); Poulsen, *Etruscan Tomb Paintings* (1922).

Etruria, a village of Staffordshire, now in the county borough of Stoke-on-Trent. Here, in 1769, Josiah Wedgwood (q.v.) and Thomas Bentley (1731-80) opened their celebrated Etruria potteries, so named after the Etruscan ware.

Ettmüller, ERNST MORITZ LUDWIG, a learned German philologist, was born 5th October 1802, at Gersdorf, near Lobau in Saxony, and studied first medicine, next German philology and history, at Leipzig and Jena, in 1833 was called to the Zurich Academy, and in 1863 to the university there, as professor of German Literature. Here he died, 15th April 1877. Ettmüller contributed enormously to the knowledge of Middle High German and Middle Low German by his scholarly editions of the literary monuments in these dialects. In 1840 he edited *Beowulf*, in 1850 an Anglo-Saxon chrestomathy;

in the following year appeared his much-valued *Lexicon Anglo-Saxonicum*. Ettmüller also studied old Norse literature, edited the *Vauluspá*, translations, and a Norse reading-book. He also published original verse, and *Herbstabende und Winternächte, Gespräche über Deutsche Dichtungen und Dichter* (3 vols. 1865-67).

Ettrick Water, a stream of Selkirkshire, rising on Capel Fell, and winding 32 miles north-eastward, past Thirlestane Castle, Tushielaw, and Philiphaugh, till, after a total descent of 1500 feet, it joins the Tweed, 3 miles below Selkirk, and 5 from the influx of its chief affluent, the Yarrow. In Ettrick churchyard, towards the stream's source, lie Boston and Hogg the 'Ettrick Shepherd.' Ettrick Forest, erst so 'fair,' now treeless and pastoral, included all Selkirkshire, with parts of Peebles and Edinburgh shires. It was a favourite royal hunting-ground till James V.'s expedition against the Border thieves (1529), after which deer gave place to sheep. See Craig-Brown's *History of Selkirkshire* (1886).

Etty, WILLIAM, R.A., painter, was born at York, 10th March 1787, the son of a miller and spice-maker. For seven years he was apprenticed to a printer in Hull, working at art during every moment that could be spared from his uncongenial employment. In the beginning of 1806 he removed to London, where in 1807 he became a student in the Royal Academy schools; and for a year he was a pupil of Sir Thomas Lawrence. His progress was at first slow; he competed unsuccessfully for prizes and medals; but in 1811 his 'Sappho' was hung in the Royal Institution, and his 'Telemachus rescuing Antiope' found a place on the walls of the Royal Academy. In 1820 he produced 'Pandora,' followed by 'The Coral-finders' (1820) and 'Cleopatra's Arrival in Cilicia' (1821). In 1822 he spent eighteen months in Italy—to which he had made a very brief visit in 1816—studying the works of the great masters, especially the Venetians, upon whom his own practice as a colourist is very distinctly founded. Two years later he was elected A.R.A., and soon after he began a series of large subjects—'Woman pleading for the Vanquished' (1825), three scenes from the history of Judith (1827-31), and 'Benaiah' (1829), all of which were acquired by the Royal Scottish Academy, and now hang in the National Gallery of Scotland. In 1828 he attained full academic honours. Among his other chief works are 'Youth at the Prow and Pleasure at the Helm' (1832), in the National Gallery, London; 'The Sirens' (1837), in the Manchester Institution; and three subjects from the career of Joan of Arc, executed shortly before his death, which occurred at York, 13th November 1849. As a colourist Etty ranks at the very head of the English school. His painting of flesh is distinguished by the utmost richness, delicacy, and refinement, and the glowing, blending hues of his draperies and of his landscape backgrounds are in admirable harmony with his figures. His drawing is too frequently mannered and inaccurate, though it occasionally possesses style and distinction. He was an indefatigable student of the living figure, and some of his most exquisite works are studies executed in the Life School of the Royal Academy, which he attended during most of his life. See Autobiography in *Art Journal* (1849); and Life by A. Gilchrist (1855).

Étude, a term used in music to designate compositions intended either to train or to test the player's technical skill. It is applied equally to pieces written for the beginner as to those written for the skilled expert, no matter what his instrument be.

Etymology (Gr.), the investigation of the origin or derivation and of the original significa-

tion of words. It forms a subsidiary part of the science of comparative philology, and, though it has occupied the attention of the learned and the curious in every age, it is only within the 19th and 20th centuries that its study has been pursued on scientific principles. Ignorance, or what is still more dangerous, half-knowledge, has often suggested false etymologies, and many more have sprung from that excess of confident and self-sufficient ingenuity which will not take plain words like *beef-eater* and *welsh-rabbit* for what they are. Folk-etymology, properly so called, has played an important rôle in the development of languages. The words that the people have known from their infancy are for them things, but it is quite different with the new terms they meet. These arrest their curiosity, and, as they believe that every word has its signification, they seek for this, guided by resemblances of sound with words already known, and consequently reach conclusions often hopelessly distorted by false analogies. We see the same illogical process in the Old Testament interpretation of personal names, applied conveniently after the fact; in the Homeric explanations of the names of gods and men; in the quaint etymologies so common in medieval writers, and in such moderns as Thomas Fuller; in the vagaries of our Celtic topographers; and even in the pages of some modern dictionaries it is possible to find such a statement as that the English word *news* is derived from a certain conjunction of the points of the compass, N. E. W. and S. These whimsical etymologies were laughed at by Dean Swift, whose *ostler* = *out-stealer*, was a stroke of genius, but have not yet disappeared; and, indeed, the modern Englishman's ideas of method in etymology are hardly at all beyond the point attained by the grammarians of Alexandria and by Varro among the Romans. It was the birth of philology and the study of the languages of the East that made a scientific etymology possible. It no longer sought the relations of the words of a single language exclusively within itself, but extended its view to the whole group of cognate tongues, or, wider still, to a whole family, and became a new science under the name of Comparative Grammar. Grimm's Law was the first finger-post that pointed out the path; among his greatest successors are Curtius and Fick. The Teutonic revival within England in the 19th century commenced the history of English upon an historical method, from which has grown a really scientific English etymology, as seen in the dictionaries of Skeat, Murray, and Weekley. No more useful chart of warning could be given than Professor Skeat's canons for etymology: 'Before attempting an etymology, ascertain the earliest form and use of the word, and observe chronology. If the word be of native origin, we should next trace its history in cognate languages. If the word be borrowed, we must observe geography and the history of events, remembering that borrowings are due to actual contact.' See Curtius, *Grundzügen der Griechischen Etymologie* (5th ed. 1879); Fick, *Vergleichendes Wörterbuch der Indo-germanischen Sprachen* (4th ed. Gött. 1890 et seq.); Karl Andresen, *Ueber Deutsche Volksetymologie* (6th ed. 1899); and A. S. Palmer's *Folk-Etymology* (1882).

Etymologicum Magnum is the name of a Greek lexicon, the oldest of the kind, professing to give the roots of the words. It appears to belong to the 10th century; the author's name is unknown. The etymologies are mere guesses, sometimes right, often wildly absurd; but the book is valuable, as containing many traditions and notices of the meanings of old and unusual words. There is an edition by Schafer (Leip. 1816); one by Sturz, called *Etymologicum Gudianum* (Leip. 1818); and another by Gaisford (Oxford, 1849).

Etzel. See ATTILA.

Eu, a town in the French department of Seine-Inférieure, on the Bresle, 2 miles from its mouth, and 21 N.E. of Dieppe by rail. It is remarkable for its fine 13th-century Gothic church, and for the Château d'Eu (1578), a low building of red brick, with high, tent-shaped roofs of slate. The seat from 996 of the Counts of Eu, a collateral branch of the Norman ducal line, after various vicissitudes Eu was purchased by Mademoiselle de Montpensier in 1675, whose fanciful taste has perpetuated itself in the decoration of the château; eventually, in 1821, it came to Louis-Philippe, who expended large sums on the embellishment of the château and its park, and who here received Queen Victoria in 1843. In 1874 Viollet-le-Duc restored it for the Comte de Paris. Pop. 6000.

Eubœa (ancient *Eubota*, Turk. *Egripo*, Ital. *Negroponte*), an island of Greece in the Ægean Sea, runs parallel to the mainland for 98 miles, its breadth varying from 30 miles at its widest part to barely 4 at its narrowest. Area, 1420 sq. m., or a little smaller than Suffolk. About midway along its west shore, near Chalcis, the strait (Euripus) separating Eubœa from the mainland contracts to 120 feet, and is spanned by two bridges, resting on a rocky islet in the middle. The island, which has its long axis disposed north-west and south-east, is traversed longitudinally by a chain of mountains, rising in the centre, in Mount Delphi, to an elevation of 5725 feet. Iron and copper occur in the mountains; and at Carystos, in the south of the island, the marble called *cipolino*, so largely used in the buildings of Rome, is quarried. Hot springs (sulphur) exist in the north. Although the east coast is steep and rocky, the west side of the island slopes gradually, and its pastures support numerous herds of swine, sheep, and goats, while the arable land produces wheat, oil, figs, and wine. Honey also is an important article of trade. The declivities of the mountains are covered with forests. The climate is salubrious. The chief towns are Chalcis (q.v.) on the west coast and Carystos (pop. 3000). Population of nome (including some smaller islands) 133,000, mostly Greeks and Albanians. Eubœa was peopled in early historic times chiefly by Thessalian tribes and by Ionic Greeks, and afterwards by colonists from Athens, who formed a number of independent cities or states. Of these the most powerful were the rival commercial cities of Chalcis and Eretria; and it is around them and their exploits that the history of the island for some centuries mainly concentrates itself. After the Persian wars, however, Eubœa was subjugated by the Athenians, under whose rule it continued till they, in their turn, were subdued by Philip of Macedon. By the Romans it was finally united with the province of Achaia under Vespasian. In 1351 it came into the possession of the Venetians, and received the name of Negroponte. In the year 1470 the island was taken by the Turks, in whose hands it remained till 1821, when the inhabitants rose to vindicate their independence at the call of the beautiful Modena Marrogonia. Subsequently (1830) it was incorporated in the kingdom of Greece.

Eucalyptus, a genus of Myrtaceæ, including about 200 species, which form the preponderant and most characteristic vegetation of the Australian forest. Their frequently enormous height (150-350 feet), their entire leathery glaucous leaves, which turn vertically with their edges to the sun, and so cast no shadow, and their frequently ragged bark and peculiar aromatic odour combine to give a unique and unmistakable character. Many species are known as gum-trees, from their resinous exudations. The Blue Gum Tree of Tasmania (*E. Globulus*) is best known in Europe as a hygienic agent in malarial

ous situations, and has been planted extensively in Italy, &c. Its value is ascribed to its rapid growth (sometimes over 10 feet per annum), and the consequent drainage of the soil. Eucalyptus leaves yield essential oils on distillation. Oils rich in eucalyptol are used therapeutically, those with less are best for extracting minute particles of minerals from 'tailings' of mines. The culture of Eucalyptus has also been introduced with good results into Algeria, Mexico, the Cape, &c. The Red Gum Tree (*E. rostrata*) yields a red astringent resin, once known as Botany Bay Kino; and *E. robusta*, the Swamp Mahogany Tree, has also a beautiful red gum. *E. viminalis* yields a copious

Eucalyptus Amygdalina.

sweet exudation from its bark and leaves, which is sold as Eucalyptus manna, and resembles genuine Manna (q.v.) in properties. That of the South Australian Mallee, *E. dumosa*, is also gathered for food from the ground, on which it lies like hoarfrost. *E. amygdalina* (a 'Peppermint') is remarkable both for height and girth. The timber of the Iron-bark (*E. paniculata*) is much used in shipbuilding and engineering, and is peculiarly suitable for girders, being of great strength and durability. Probably the most widely used species are the Western Australian Jarrah (*E. marginata*) and Karri (*E. diversicolor*), the former especially valuable for piles and sleepers, the latter for bridge-decking, and both for street-paving. The bark of some species is useful as a source of tannin; whilst a liqueur made of Eucalyptus is drunk in Italy. The seeds were first sent from Melbourne to Paris by M. Ramel in 1854. See TIMBER, WESTERN AUSTRALIA, Warren's *Australian Timbers* (1900), and J. H. Maiden's *Critical Revision of the Genus Eucalyptus* (1903, &c.).

Eucharist. See LITURGY, LORD'S SUPPER.

Euchlorine is a very explosive green-coloured gas, possessing bleaching properties, and is prepared by the action of strong hydrochloric acid on chlorate of potash. It is dangerously explosive by heat, and its composition is still a matter of discussion. It is generally supposed to contain chlorine peroxide and free chlorine.

Euchre, a game at cards, very popular in America, but not played until the first quarter of the 19th century. Euchre is played with a pack of thirty-two cards (all cards below a seven being rejected). The cards rank as at whist, with the exception of the *bowers*. Knave of the trump suit (*right bower*) is the best trump; knave of the same colour (*left bower*) is the next best,

that card belonging to the trump suit. Each player receives five cards from the dealer, by two or three at a time, the top card being then turned up for trumps. When two play, the non-dealer either *orders up* the trump, and plays his hand, or *passes*. If he orders up, the dealer discards a card, and substitutes the trump card for it. If he passes, the dealer either *takes up* the trump (discarding as before), and the hand is played, or *passes*. This he signifies by turning down the trump. If both pass, the non-dealer may name any other suit for trumps (called *making it*), or may pass again. If he passes, the dealer may make it. If either makes it, the hand is then played; if both pass again, the hand is thrown up, and the opponent deals. If the hand is played, the non-dealer leads; the dealer plays, and must follow suit, if able. The highest card wins the trick; trumps win other suits, and the play continues as at whist. A player ordering up, or taking up, or making the trump, and winning five tricks (called a *march*), scores two; if he wins three tricks (called the *point*), he scores one. If he fails to make three tricks, he is *euchred*, and his adversary scores two. The game is five up. When four play, they cut for partners, as at whist. If the first hand passes, the second may *assist*, when his partner (the dealer) takes up the trump, and the hand is played. If a player has a very strong hand, he may *play alone*—single-handed against both adversaries; and if a lone player wins five tricks, he scores four. Euchre is sometimes played by three persons (*cut-throat euchre*); but the game most in vogue among good players is the four-handed.

Eucken, RUDOLF CHRISTOPH, born 5th January 1846 at Aurich in East Friesland, studied at Göttingen and Berlin, and became professor first at Basel and then, in 1874, at Jena. Like Bergson's, his philosophy is an 'activism' nearer the ethical idealism of Kant and Fichte than the intellectualism of Hegel, and is the struggle for the spiritual control of life, a vindication of the significance and worth of life; man being a co-worker with the divine. He would end the conflict between religion and modern culture in a new idealism. Most of his principal works have been translated, e.g. *The Problem of Life* (1909), *The Life of the Spirit* (1909), *Life's Basis and Life's Ideal* (1910), *Main Currents of Modern Thought* (1912), *Present-day Ethics* (1913), *Collected Essays* (1914), *Socialism* (1921), and *Rudolf Eucken: his Life, Work, and Travels* (1921). See *Eucken*, by A. J. Jones (1912).

Euclid is known to us almost exclusively from those of his works which have survived. Proclus in his commentaries on the first book of the *Elements* mentions that Euclid lived in the time of Ptolemy I of Egypt, that he was younger than Plato, but older than Archimedes and Eratosthenes. Hence 300 B.C. may be taken as an approximate date for the middle of his career. He taught in Alexandria, and probably was the founder of its illustrious mathematical school. His chief extant work is the *Elements* in thirteen books. Books i.-iv. and vi. treat of plane geometry; v. of proportion in general; vii.-ix. of the properties of numbers; x. of incommensurable magnitudes; xi.-xiii. of solid geometry. Besides the *Elements*, there are the *Data*, a collection of geometrical theorems, and the *Phenomena*, or appearances of the heavens. Regarding the genuineness of the *Section of the Scale, Introduction to Harmony, Optics, Catoptrics*, and *Divisions of Superficies*, commentators are divided in opinion, though they lean rather to the view that most if not all of these writings are spurious. Some other works not now extant are attributed to Euclid. The only one of any importance was the treatise on *Porisms*. Euclid's *Elements*

has been translated into many languages, and is probably better known (or was till lately) than any other mathematical book. With many of its blemishes removed and its deficiencies supplied, was widely used in Britain as a text-book of geometry after it had long been almost universally given up in Europe and America.

The first printed edition of Euclid was a translation from Arabic into Latin, which appeared at Venice in 1482. The first printed Greek text was published at Basel in 1533. Gregory's edition (Oxford, 1703) contains all the works attributed to Euclid. Standard modern editions are those of Heiberg (5 vols. Copenhagen, 1883-88), and T. L. Heath (3 vols. 1908-9). For an account of what the Greeks had done in geometry before Euclid's time, and for Euclid's own achievement, see Cantor's *Geschichte der Mathematik* (1880-92); W. B. Frankland's *Story of Euclid* (1902); Dodgson's *Euclid and his Modern Rivals* (1879); and Perry on *The Teaching of Mathematics* (1901).

Euclid of Megara, a Greek philosopher, who has often been confounded with the mathematician of the same name. He was one of the chief disciples of Socrates, but had previously studied the dialectics of the Eleatics; on one occasion Socrates declared that his pupil's subtle logic might win sophists, but never men. After the death of his master (399 B.C.), Euclid established a school of his own, which received the name of the Megaric School. The basis of his system was the Eleatic dogma of a one, only, universal existence; and, blending with this the Socratic idea of the predominance of the moral element, Euclid held this one real existence to be the *Good*, though it receives various names under its special manifestations.

Eudæmonism, the doctrine that happiness (*Gr. eudaimonia*) is the chief good. See **ETHICS**.

Eudiometer. See **GASES**.

Eudocia, the name of several Byzantine princesses. Of these the most celebrated was the wife of Theodosius II. Pulcheria, the emperor's sister, who from her sixteenth year (414) had directed the government under the weak-minded emperor, chose Athenais (born 401), the beautiful and accomplished daughter of an Athenian sophist Leontius, to be her brother's wife. She renounced paganism, took the name of Eudocia, and was married to Theodosius in 421. Soon afterwards a violent rivalry arose between the two sisters-in-law. On the outbreak of the Nestorian controversy, Eudocia took the side of Nestorius, and Pulcheria, conspiring with Cyril of Alexandria, brought about his fall. During the last four years of Theodosius, Pulcheria was banished from the court, and the doctrines of Eutyches (q.v.) and Dioscuros—the opposite of Nestorianism—were victorious at the 'Robber Synod' of Ephesus (449) through the influence of Eudocia. But shortly before the emperor's death (450) Pulcheria regained her former influence, while Eudocia fell into disgrace and retired to Jerusalem, where she spent the remainder of her life in works of piety and charity, and died in 460. Eudocia wrote a panegyric on the victories of Theodosius over the Persians, paraphrases of Scripture, and a poem on the legend of St Cyprian. The *Homero-cento* on the Life of Christ (consisting of 2343 hexameters made up of verses and half-verses culled from Homer), doubtfully attributed to her, was edited by Teucher (1793). See **BYZANTINE EMPIRE**; and Miss Teetgen, *The Empress Pulcheria* (1907).

Eudoxus of Cnidus, called by Cicero the prince of astronomers, flourished about 370 B.C. He studied under Plato for some time, and afterwards went to Egypt, where he derived much knowledge from the priests. He is said to have introduced an astronomical system of homocentric spheres into Greece, and the year of 365½ days, likewise to have distinguished true astronomy from astrology.

Euganean Hills, a range of well-wooded hills, with a north and south axis, lying SW. of Padua in northern Italy. They owe their origin to eruptions of trachyte during the Jurassic period. The highest point, Monte Venda, reaches 1749 feet. On their slopes stand several villas, amongst them Petrarch's house at Arquà.

Eugene, PRINCE. François Eugène, commonly called Prince Eugene of Savoy, one of the greatest generals of his time, was born at Paris, 18th October 1663. He was the youngest of the five sons of Eugene Maurice of Savoy-Carignan, Count of Soissons (grandson of the Duke of Savoy, Charles Emmanuel I.), and of Olympia Mancini, a niece of Cardinal Mazarin. He was intended for the church, but had a strong predilection for the camp, and, after his father's death (1673), his mother's banishment from court by command of the young king Louis XIV., and the latter's refusal to give him a commission, he indignantly renounced his country, and at twenty entered the service of the Emperor Leopold as a volunteer against the Turks. He early displayed extraordinary courage and tactical talent in the Turkish war, especially at the famous siege of Vienna in 1683, and rose rapidly in rank. In the Coalition War against Louis XIV. in Italy, he covered himself with the glory peculiar both to the soldier and the general; he became field-marshal in 1693, and overwhelmed the Turks, who left 30,000 dead on the field, in the famous battle of Zenta, September 11, 1697, which put an end to their power in Hungary. The outbreak in 1701 of the Spanish War of Succession recalled him to the command of the army of Italy, but though he displayed a strategy worthy of Hannibal, inflicted several severe defeats upon the French, and even captured the Duke of Villeroy in Cremona by a daring night-attack, he was prevented from effecting anything of importance by the smallness of his own forces and the skilful tactics of the Duke of Vendôme, who inflicted upon him a severe defeat at Luzzara (15th August 1702). Becoming in 1703 president of the council of war, he took the command of the imperial army in Germany, and helped Marlborough to gain the brilliant victory of Blenheim (13th August 1704). Eugene was checked at Cassano (August 16, 1705) by Vendôme, and twice wounded in the field, but after a daring march appeared before Turin and crushed the French in a complete defeat which closed their career in Italy. He shared with Marlborough the glory of the fields of Oudenarde (in 1708) and Malplaquet (in 1709); but, being crippled in his resources by the retirement of Holland and England from the contest, he was unable to withstand the enemy on the Rhine, and his defeat by Villars at Denain (24th July 1712) was followed by other disasters, until the peace of Rastadt (6th March 1714) put an end to the war. On the recommencement of the war (in 1716) against the Turks, Eugene with but 64,000 men defeated an army of 150,000 men at Peterwardein, took Temesvar, and in the year 1717, after a desperate battle, carried Belgrade by assault. He had already lain for a month before the city contending against dysentery and a force six times his own, when he determined to stake everything upon a general attack. In the bloody struggle Eugene received his thirteenth wound.

After the peace of Passarowitz (21st July 1718), he returned covered with glory to Vienna, where, during the succeeding years of peace, he laboured with unwearied energy in the cabinet. When the question of the succession to the throne of Poland brought on a new war with France, Eugene appeared again on the Rhine, but owing to insufficient resources and failing vigour he was unable to do more than keep the enemy out of Bavaria. After the peace, he returned to Vienna, where he died,

21st April 1736. Prince Eugene was of middling stature, his face thin and long; his eager dark eyes alone revealed the vigour of his nature. His dress was plain and simple like his manners; he had no passion but that of glory; no appetite save an inveterate relish for snuff. Although a strict disciplinarian and a general who risked his soldiers' lives as freely as his own, he was worshipped by his men, and he has gone down to posterity as a hero in popular song. As 'Prinz Eugen, der edle Ritter,' his memory is green with thousands who never heard of his campaigns. He introduced no new tactics in the art of war, and was deficient in the guidance and command of masses; but by his rapidity of perception and decision, and faculty for turning to instant advantage existing circumstances, he raised the prestige of the Austrian arms to an eminence unequalled before or since his time. He successively served under three emperors, of whom he was wont to say that in Leopold I. he had a father, in Joseph I. a brother, and in Charles VI. a master. Compare Dumont, *Histoire Militaire du Prince Eugene* (with continuation, 1823-29), and the monographs of Kausler (1838-39), Arneth (1858-59), Von Sybel (1861), and Col. Maleson (1888).

Eugenia, a genus of Myrtaceous trees and shrubs, allied to the myrtle, pimento, and clove. See MYRTACEÆ, PIMENTO, CLOVE.

Eugenics.—The word eugenics is derived from the Greek word *eu* *genēs*, which is defined in Liddell and Scott as meaning well-born. The word was first used by Francis Galton, the founder of the science, in *Inquiries into Human Faculty*, which was published in 1883 by Macmillan, and reprinted later in the 'Everyman's Library.' On p. 17 of the reprint the word occurs in the following sentence, 'Its (i.e. the book's) intention is to touch on various topics more or less connected with that of cultivation of race, or, as we might call it, with "eugenic" questions,' and in a footnote to the word 'eugenic' we find the following definition, 'That is, with questions bearing on what is termed in Greek *u* *genes*, namely, good in stock, hereditarily endowed with noble qualities. This, and the allied words, *eugeneia*, &c., are equally applicable to men, brutes, and plants. We greatly want a brief word to express the science of improving stock, which is by no means confined to questions of judicious mating, but which, especially in the case of man, takes cognisance of all influences that tend, in however remote a degree, to give to the more suitable races or strains of blood a better chance of prevailing speedily over the less suitable than they otherwise would have had. The word *eugenics* would sufficiently express the idea.' The word occurs at least four more times in the course of this book: (1) on p. 19, 'In any scheme of eugenics, energy is the most important quality to favour;' (2) on p. 30, 'The investigation of human eugenics—that is, of the conditions under which men of a high type are produced—is at present extremely hampered by the want of full family histories, both medical and general, extending over three or four generations. There is no such difficulty in investigating animal eugenics . . . Believing, as I do, that human eugenics will become recognised before long as a study of the highest practical importance, it seems to me that no time ought to be lost in encouraging and directing a habit of compiling personal and family histories;' (3) on p. 199, 'The most merciful form of what I ventured to call "eugenics" would consist in watching for the indications of superior strains or races, and in so favouring them that their progeny shall outnumber and gradually replace that of the old one;' (4) on p. 211 there is a section dealing with 'Marks for Family Merit,' in which the

subject of the possible improvement of race being undertaken by man is considered. It is regarded at the moment as Utopian, but Galton proceeds to sketch out faintly 'some sort of basis for eugenics.'

The ideas here expressed were far in advance of the age, and, though evidently much in Galton's mind, it was nearly twenty years before he again brought the subject of eugenics as a possible science before the public. In 1901 Galton gave the second Huxley Lecture, which was entitled, 'The Possible Improvement of the Human Breed under the Existing Conditions of Law and Sentiment' (*Nature*, vol. lxiv. p. 659 *et seq.*). This lecture was described by Galton as an attempt to 'induce anthropologists to regard human improvement as a subject that should be kept openly and squarely in view, not only on account of its transcendent importance, but also because it affords excellent but neglected fields for investigation.' He goes on to show that the natural character and faculties of human beings vary, and that though talents are distributed in different degrees, the frequency of those degrees follows certain statistical laws, of which the best known is the Normal Law of Frequency. He deals with the question of marriage of like to like in each class of society, and points out how qualities descend in a population, and how the intelligence of a community could be raised by concentrating attention on the more intelligent members of it and securing them as parents. He says that among the Utopias in which he had indulged was one of a great society 'publishing intelligence and memoirs, holding yearly elections, administering large funds, establishing personal relations like a missionary society with its missionaries, keeping elaborate registers and discussing them statistically with honest precision;' but Galton felt at the same time that a crusade in favour of race improvement must be justified, and an unbiased scientific inquiry along many roads must be started with that end in view. Throughout this lecture the word eugenics never occurs, but in 1904, at a meeting of the Sociological Society, Galton gave a paper on 'Eugenics: Its Definition, Scope, and Aims' (*Sociological Papers*, vol. i. p. 45 *et seq.*; *Essays in Eugenics*, by Francis Galton, the Eugenics Education Society, 1909, p. 35), in which he defined eugenics as 'the science which deals with all influences that improve the inborn qualities of a race, also with those that develop them to the utmost advantage.' Galton considered that there were three stages to be passed through before eugenics could be regarded as of national importance: (1) It must be made familiar as an academic question; (2) it must be recognised as a subject whose practical development deserves serious consideration; and (3) it must be introduced into the national conscience like a new religion. It was obvious from the discussion that followed the paper that the first stage was very far from being passed, and towards the end of 1904 Galton offered to found a fellowship for the study of 'National Eugenics' in connection with London University. In 1905 the first Galton Fellow, Mr Edgar Schuster, was appointed, and a 'Eugenics Record Office' was started. In this same year Galton gave three further papers before the Sociological Society, 'Restrictions in Marriage,' 'Studies in National Eugenics,' and 'Eugenics as a Factor in Religion' (*Sociological Papers*, 1906, vol. ii. p. 3 *et seq.*), in which he dealt with points that had been raised by his former paper on eugenics, and discussed possible lines of inquiry.

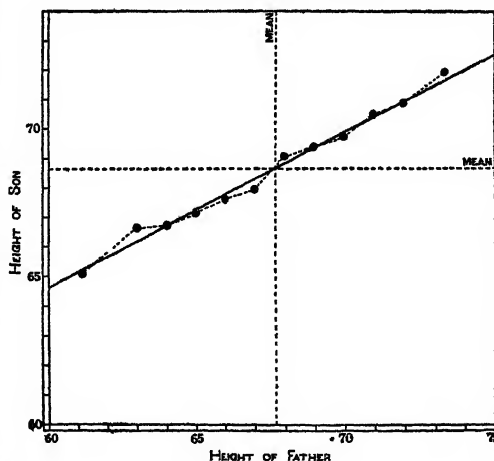

In 1907, when the term of Mr Schuster's office as Fellow was ended, Galton, with the consent of the University of London, decided to form the Francis Galton Laboratory for the Study of National Eugenics, which was to be under the supervision of Professor Karl Pearson, the director of the

biometric laboratory, in consultation with Francis Galton. Mr David Heiron was appointed the second Galton Research Fellow, and a Francis Galton Scholar and a computer were added to the staff. By attaching his new laboratory to the biometric laboratory, Galton emphasised what he regarded as a very important point, that the science of eugenics should use what were then the new methods of statistical analysis associated with the word biometry and the journal of *Biometrika*, and in that same year he took as the title of his Herbert Spencer Lecture, *Probability, the Foundation of Eugenics* (1907). He there gives what he describes as 'Object-lessons in the Methods of Biometry,' since popular ignorance of biometry obstructs the path of eugenics. Galton felt that probability could yield results sufficiently exact to afford a foundation for eugenic action, but that such action would only be possible if public opinion were behind it, and that much research must be carried out before the necessity of legislative or other action could be made clear and conclusive to public opinion. In 1911 Francis Galton died, and left the residue of his estate to the University of London for the establishment of a professorship and laboratory of National Eugenics, and expressed the wish that the post of first Galton professor should be offered to Professor Karl Pearson on such conditions as 'will give him liberty to continue his biometric laboratory.' The study of national eugenics in the will was defined as the study 'of the agencies under social control that may improve or impair the racial faculties of future generations physically and mentally.' In the meantime interest in eugenics had been spreading. Galton's papers given to the London Sociological Society were reprinted in *The American Journal of Sociology* (Chicago, 1904-5, vol. x. pp. 1-25, and vol. xi. pp. 11-25), and translations in German were published in the *Archiv für Rassen und Gesellschafts-Biologie* (Berlin, 1905, vol. ii. p. 812 et seq.). Dr Alfred Ploetz, one of the editors of that journal, gave much encouragement to the new science, and in 1905 founded a society, 'Internationale Gesellschaft für Rassen-Hygiene,' to carry out research in inheritance and variation, and to make the results public. In England the Eugenics Education Society was founded in London in 1907-8, the rules of the society were approved at a meeting held in December 1907, the first general meeting of the society was held in February 1908, and the first number of the journal of this society, *The Eugenics Review*, was published in April 1909. Branches of the Eugenics Education Society were soon started in various towns in the United Kingdom and in the colonies. A 'Eugenics Record Office' was established in New York in October 1910, and issued its first report in 1913. In Germany eugenics does not seem to have become a popular word, and 'race hygiene' was generally substituted. Branches of the international society for race hygiene grew up in other places in Germany and in Sweden, and a joint general meeting of the Deutsche and of the Internationale Gesellschaft für Rassen-Hygiene was held in Dresden in 1911. The first International Eugenics Congress was held in London in July 1912, under the auspices of the Eugenics Education Society. The subject found its way into many journals in all countries. In Italy Professor Gini, Professor Sergi, and others published their papers mainly in the *Rivista Italiana di Sociologia* (Rome) and in the *Rivista di Antropologia* (Rome). In France 'La Société Française d'Eugénique' was founded, and published the first number of its journal *Eugénique* in 1913, but many papers had appeared previously in various journals, and French interest in eugenics is of an earlier date. A new journal, *Archiv für Frauenkunde und Eugenik* (Würzburg),

edited by Dr Max Hirsch, was first published in March 1914. In the Scandinavian countries interest in biometric and eugenic inquiries was aroused, practical suggestions for race improvement were made, and papers on race hygiene were published at an early date, and books were issued by Professor J. A. Mjoen (Kristiania, 1915), and by Dr Lundborg (Stockholm, 1914).

The need of a science of eugenics does not exist in any state in an early stage of development. When the very existence of man depends on his own strength and power to look after himself, which means, broadly speaking, on his physical condition and mental soundness, only the stronger will survive, and natural selection, by weeding out all who fall much below the average, keeps a race healthy physically and mentally. On the other hand, when man with increasing civilisation develops a social conscience which expresses itself in sympathy with weakness, in caring for the diseased in mind and body and with those unable to battle for themselves, and further, when increasing medical knowledge enables some who left to nature would die early, to live, to marry, and to have children, then natural selection is partially suspended, and race improvement, if it is to come at all, must be undertaken by man. Those who believe in the necessity for eugenics are influenced chiefly by three factors—by a belief in the power of heredity, by the knowledge that fertility is greatest among the less desirable members of the community, and, thirdly, by the belief that natural selection is largely suspended. It is in the conjunction of the three that the danger for the race exists. The strength of heredity in physical and mental characteristics is now well established owing mainly to the work of Francis Galton and Karl Pearson. The characteristics of a child are determined by the presence or absence of those same characteristics in the parents and family of the child. Using the mathematical theory of statistics, we can determine not what will happen to the next child of any one particular marriage, but what will happen on the average to the children of a certain type of parent. Given sufficient information about the two families that are intermarrying, it is possible to foretell the sum of good or evil that such a marriage will mean for the children. The fuller the family history, the more nearly we can predict what the result

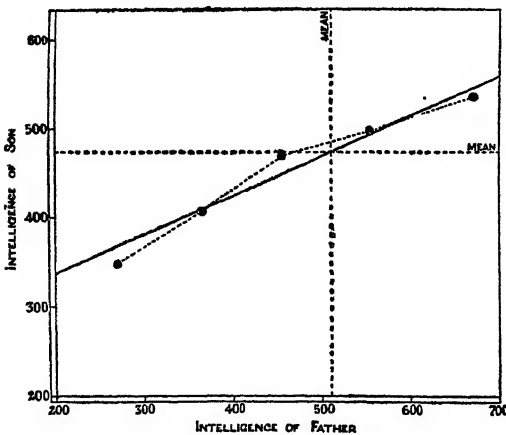

INHERITANCE OF STATURE

of any marriage will be. The two diagrams show the inheritance of stature and intelligence between father and son, and from the data we can determine not only what the average height and intelligence

of the sons of a certain type of father may be, but also the limits within which the sons of a given father are likely to be found. If the average height of a father be 65 inches, and nothing is known about the mother, we can state that the average

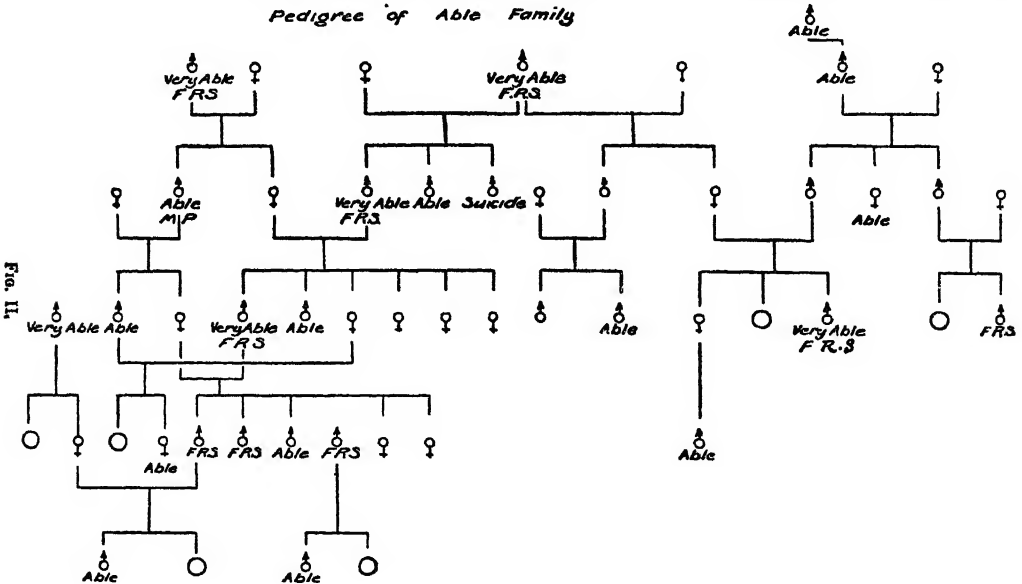

INHERITANCE OF INTELLIGENCE

height of the sons of all such fathers will be 67.2 inches, and that 75 per cent. of the sons will be found to be not less than 64.1 inches and not more than 70.3 inches in height; but if the father is 6 feet, we can say that the average height of sons of this type of father will be 70.9 inches, and that

75 per cent. of the sons will be found to be not less than 67.8 inches or more than 74 inches in height. If we take the inheritance of intelligence in middle-class families in which no parents of very low grade of intelligence are included, and measure that intelligence in units, which can be called mentaces, we find that the average number of mentaces possessed by these fathers is 510, and that the groups vary from 'slow' fathers who have an average of 269 mentaces, to the very able who have an average of 672 mentaces. Fathers whose intelligence is measured by only 269 mentaces will have sons who on the average have 348 mentaces, and we can say in round numbers that 87 per cent of their sons will have less than 457 mentaces, that is to say, will be well below the average intelligence of this community; while, if the father's intelligence is measured by 672 mentaces, the average for the sons will be 535, and 87 per cent. of these sons will have more than 426 mentaces. The pedigree of an able family, reproduced by permission from a lecture by Professor Pearson on *The Scope and Importance to the State of the Science of National Eugenics* (Eugenics Laboratory Lecture, series i.), illustrates the inheritance of intelligence in another way; and pedigrees showing the inheritance of commercial and legal ability will be found in the first volume of the *Treasury of Human Inheritance*, another publication of the Eugenics Laboratory. General health and many diseases are inherited in practically the same degree as stature and intelligence. The following pedigrees of mental defect and deaf-mutism are reproduced, by permission, from the *Treasury of Human Inheritance* (Eugenics Laboratory Memoirs,

Pedigree of Able Family

series ix. and xi. part iii. plate xix. fig. 177, and part iv. plate xxvii. fig. 273). Fig. 177 illustrates the inheritance of mental defect. In the second generation a normal man, of whose parents nothing is known, but who had an insane sister, married an alcoholic 'dull' woman, daughter of an insane woman, and sister of an insane man and of an epileptic woman. Of the children of this marriage, seven were imbecile or mentally weak and four died young. The youngest daughter married a tuberculous man, and fortunately there were no children. The other pedigree shows the inheritance

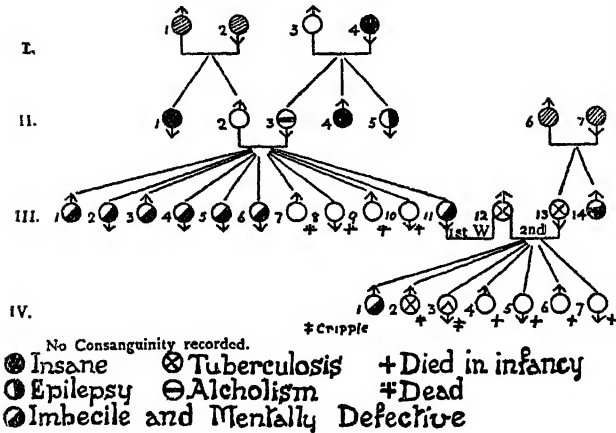

of deaf-mutism. In the first generation two deaf-mutes (I. 8a and 8b) married, and had a deaf-mute child, who married a deaf-mute, and had seven normal children and one deaf-mute son, who married a deaf-mute woman as her second husband, and had three children, the eldest deaf-mute, the second normal, and the third died aged five months, condition unknown. In the second generation in this pedigree there were three marriages of deaf-mutes, resulting in the birth of seven deaf-mutes and one person partially deaf. These pedigrees are only two out of thousands collected and published in

the *Treasury of Human Inheritance*, and in other publications, such as *Menschliche Erblchkeitslehre*, by Erwin Baur, Eugen Fischer, and Fritz Leny (München, 1923), showing the force of heredity; Galton's followers feel that in this direction the first stage is passed, and that heredity in mental and physical

are the children of 29 per cent., and the other half of 13 per cent., of the original generation. It is more difficult to obtain information for England with regard to the number of women who marry, but the estimates made in Denmark will probably not be very different from the conditions existing in England in 1911. In the census for England and Wales for 1911 the fertility of marriages is obtainable; and if we take only those in which the wife had reached the age of forty-five years or over, and consider that we are dealing with completed families, we obtain a diagram very similar to that found for Denmark, and find that roughly a quarter of the married people in one generation produce half the next generation. It is obvious from this that if the quarter of the married people who are more fertile belong to the less desirable members of the community, a very rapid deterioration may set in. If we consider the extreme case, and suppose that the 25 per cent. who are having seven or eight or more children belong entirely to those who are of slow or very dull intelligence, and that they marry people of the same type, then in the third generation, instead of having 25 out of every 100 slow or very dull people, we should have 50, and in

four generations we should have 96 out of 100 with this type of intelligence (see *Groundwork of Eugenics*). This has not happened; but that something of the kind has been happening has been shown by David Heron in his paper *On the Relation of Fertility in Man to Social Status* (Drapers' Company Research Memoirs, Studies in National Deterioration, No. 1), by W. C. D. and C. D. Whetham in *The Family and the Nation* (1909), by Sidney

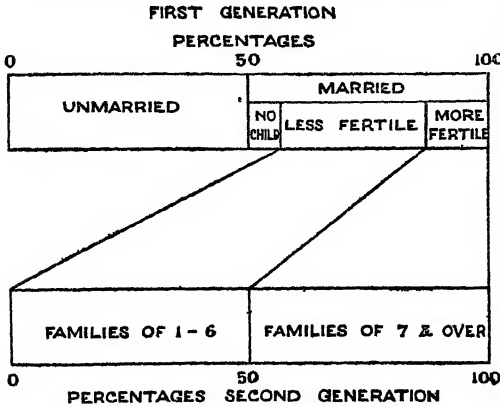

Bennett's Case

of the community, and the question is how far natural selection is righting what is obviously a serious matter for the community. It seems likely that the danger is greater on the mental and moral than on the physical side, but it is difficult to

DENMARK (RUBIN & WESTERGAARD)

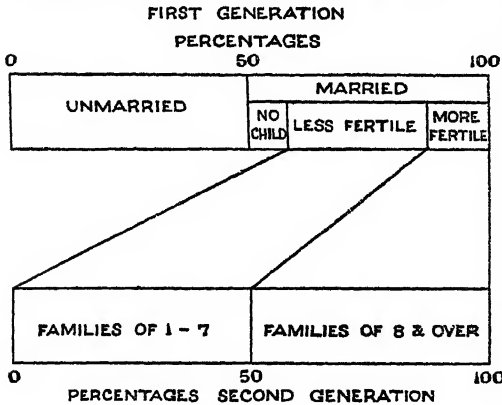

MARRIAGE LASTED 15 YEARS & OVER

measure it; parents who have bad habits, and these probably include the most stupid ones, lose more children at the very young ages than parents

CENSUS OF ENGLAND & WALES 1911

MARRIED WOMEN OF 45 YEARS & OVER

with good habits, but not to such a large extent as unhealthy parents, and this loss is probably being diminished as the infant death-rate falls. As long as the selective death-rate operates at all, many of the physically weakest in the community will die before they become adult. Professor Pearson and Dr Ploetz have both shown that when parents die young, not only will the number of their children be smaller, but that the proportion of those who die in childhood will be greater than when the parents live to a ripe old age. In well-to-do Quaker families, if the mother died between the age of nineteen and twenty-nine, 73 per cent. of

her daughters died before they were twenty-one; but if the mother lived to be over seventy, the percentage of those who died under twenty-one was halved (*The Groundwork of Eugenics*, p. 26). Dr Ploetz took the percentage of children who died under five years in 'furstlichen' and 'burgerlichen' families, and showed that the percentage who died before reaching the age of five years diminished as the age at death of the mother increased. The death-rate in the earlier years of life is now diminishing, and in this decrease some see a suspension of natural selection, but though decreasing, it would seem unlikely that natural selection on the physical side will ever be entirely suspended. Physical and mental disabilities seem to be no bar to marriage, judging by the pedigrees that can be studied, and we cannot hope that improvement of the race will come through a selective marriage rate. It seems that it must come through the selective death-rate or through the conscious action of man. We have obtained some evidence as to the power of the selective death-rate, as it still exists, from data collected in working-class districts by medical officers of health. Here we could not deal with families that were completed or nearly completed, and groups of mothers had to be considered whose ages did not widely differ. We see from the table that mothers with bad health and bad habits at each age-group have more children than their more desirable neighbours, and we also see that, on the whole, the women with bad habits have more children than the women with bad health. At ages thirty-two and over, women with bad health have had 7.5 children born, and women with bad habits have had 7.8. The selective death-rate is still operating, and the number of living children is practically the same in this district whether the mother's health is good or bad, and possibly by the time these children are adult the children of the mother with good health will be more in number than the children of the mother with bad health. The selective death-rate, however, has not been able to compensate for the larger number of children born to mothers who have bad habits; that type of mother has more children living than the mother with good habits. In another district we can group all the fathers together, and find what the number of the children would be if all the mothers were of the same age and the fathers were in two groups, one representing the men who were in regular work in 1909, and who were presumably, on the whole, the more steady and intelligent men, and the other representing the men who were irregularly employed, and we find that the regular workman had an average of 3.6 children born and 2.7 living, and that the irregularly employed man had an average of 4.1 children born and 3.0 alive. The average age of the mothers of these children was about thirty, and the difference may be expected to go on increasing, since there is very little sign of

	Age of Mother.							
	Under 25.		25-29		29-32		32 and over.	
	Children		Children		Children		Children

Mother's health good . . .	1.6	1.3	2.6	2.2	3.8	3.1	6.3	4.7
" " not good . . .	1.8	1.3	3.1	2.1	4.6	3.2	7.6	4.7
Mother's habits good . . .	1.6	1.3	2.6	2.1	3.7	2.9	6.1	4.5
" " not good . . .	1.8	1.3	3.1	2.3	4.9	3.5	7.8	5.0

the action of a selective death-rate here. These examples show that though physically we may be just stationary as a race, probably mentally and

morally we are not even stationary, but that if these characteristics are inherited, we are steadily adding to the proportion of our people possessing undesirable traits in these directions. Advance in medical knowledge now allows people suffering from certain types of disease to live to adult life, to marry and have children, as, for example, women suffering from the type of dwarfism known as achondroplasia (*Treasury of Human Inheritance*, parts vii. and viii., Eugenics Laboratory Memoirs, xv. plate li.), from the eye disease glioma retinae (*Treasury of Human Inheritance*, vol. ii. plate xxvi.), and it further enables many unhealthy babies to live to grow up. Those who believe in the necessity of race improvement being undertaken by man do not suggest that there should be less care for the weaklings, but do suggest that those who are responsible for the well-being of the state should exercise care for the individual in such a way that future generations will not suffer for the ignorance and carelessness of the present. Public opinion is now very largely in favour of attempting to repress the productivity of the worst stocks. The permanent care of the feeble-minded is a step which few consider anything but right and needful for the benefit of the individual and of the race, and the law has given its sanction; but the establishment of the necessary institutions has been hindered, first by the war, and now by the need for economy after the war. Galton considered that it was even more important to increase the productivity of the best stocks, than to repress that of the worst; he foresaw great danger to the race in checks to over-population, fearing that the doctrines would be followed only by the prudent and self-denying, whose descendants were required, and not by the impulsive and self-seeking. He believed that improvement in the race could only come from within the race, by favouring those with good 'natural tendencies,' the one thing that must inevitably assert itself. The work of Galton and others seems to show that acquired knowledge and acquired characteristics are not transmitted to the offspring, and that no betterment of the environment can effect an improvement in the race; it may assist the individual, but it will not enable him to pass on a better constitution to his children. Galton urged that some means should be found for favouring individuals who bore signs of belonging to a superior race, that some weight should be given to ancestral characters, in addition to that already given to personal ones. This he considered was necessary, owing to the fact that an individual gifted with high qualities, who is an average specimen of a good race, will have more highly qualified children than an equally gifted individual who is an exceptionally good specimen of a poor race. If we could raise the average standard of the race only one grade in ability and character, Galton showed in 1869 (*Hereditary Genius*, p. 343), that instead of having 233 really eminent men in a million, we should have 2423; and he adds, 'but far more important to the progress of civilisation would be the increase in the yet higher orders of intellect.' In man survival has followed the development of mind rather than of body, and if natural selection is still helping to preserve man's physical fitness, it seems as if eugenics must concentrate on the improvement of man's mental and moral equipment. It is probably truer now even than in 1869, that 'we are in crying want for a greater fund of ability in all stations of life; for neither the classes of statesmen, philosophers, artisans, nor labourers are up to the modern complexity of their several professions.' Galton's proposal, to improve the race by breeding men for ability and character, seems

the only practical and reasoned proposal for producing men able enough to deal with our existing complex problems. It was to the study of this question of race improvement that Galton gave the word eugenics.

Eugénie (1826-1920). See NAPOLEON III., and books by Clara Tschudi (1899), Jane Stoddart (1906), L. G. Daudet (1912), and E. Legge (1916).

Eugenius, the name of four popes, of whom the last is the most important. Gabriele Condolmiere was born in 1383 at Venice, and became pope as Eugenius IV. in 1431. The great event in his career was the schism created in the church by the proceedings of the Council of Basel, which had been convoked by his predecessor, Martin V., and showed a strong desire for ecclesiastical reform and a diminution of the papal power. Eugenius was compelled to flee from Rome in 1434 by an intrigue of the Colonna faction, whereupon he opened a new council, which met first at Ferrara, next at Florence, and issued a bull of excommunication against the bishops assembled at Basel, whom he pronounced to be 'a satanic conclave, which was spreading the abomination of desolation into the bosom of the church.' The Council of Basel formally deposed him from his pontifical office in 1439, and elected in his stead Amadeus, Duke of Savoy, under the title of Felix V. The conduct of France and Germany seemed to warrant this bold step, for Charles VII. had introduced into the former country the decrees of the Council of Basel, with some modifications, through the Pragmatic Sanction (1438), and the same thing happened in Germany by means of the Deed of Acceptance (1439). At the Council of Ferrara, John Paleologus II., emperor of Constantinople, and upwards of twenty Greek bishops, presented themselves, and a union between the two great divisions of Christendom—the Greek and Latin Church—was thus for a moment effected in July 1439. In 1444 Eugenius was able again to enter Rome, and three years later he died, just after signing a treaty of pacification by which Germany declared against the antipope. His pontificate was stormy and unhappy, and in his old age he regretted that he ever left his monastery. See BASEL (COUNCIL OF).

Eugubine Tables (Lat. *Tabulae Iguvinæ*), the name given to seven bronze tablets, the inscriptions on which present a comprehensive and very remarkable memorial of the Umbrian language. They were discovered in 1444 at Gubbio (the ancient *Iguvium* or *Eugubium*), where they are still preserved. The characters on four of the tablets are Etruscan, on two Roman, and on one partly Roman and partly Etruscan; the inscriptions run from right to left. The language employed, however, is in all cases the same, and differs both from Etruscan and Latin, but resembles somewhat the older forms of the latter and also the Oscan dialects, so far as we know them. The subjects of the inscriptions are directions concerning sacrificial usages and forms of prayer, and they seem to have been inscribed in the 1st and 2d centuries A.D. Philip Bonarota first published them in a complete form in Dempster's *Etruria Regalis* (2 vols. Florence, 1723-24). The first really judicious attempt at interpretation was that of Lanzi, in his *Saggio di Lingua Etrusca* (3 vols. Rome, 1789), who points out the important fact that they related to sacrificial usages, &c. Ottfried Müller, Lassen, Grotefend, and Lepsius continued their study; the last gave the most accurate copy of the inscriptions in his *Inscriptiones Umbricæ et Oscæ* (Leip. 1841). The best and most complete work on the language and contents of the tablets is that of Aufrecht and Kirchhoff, entitled *Die Umbrischen Sprachdenkmäler* (1849-51). See F. W. Newman, *The Text of*

the *Iguvine Inscriptions, with Latin translation and notes* (1864); and Bréal, *Les Tables Eugubines* (Paris, 1876-78).

Euhemerism, the name usually applied to the historical theory of the origin of mythology from Euhemerus, a native of Messene and a contemporary of Cassander of Macedonia in the 4th century B.C. In the course of a voyage to the Indian Sea he professed to have discovered an island called Panchaia, in which he found a number of inscriptions representing the principal gods of Greece as mere earth-born kings and heroes deified after death for their superior strength or capacity. His book, entitled *Hiera Anagraphê*, is lost, as well as its Latin translation by Ennius. It drew upon him the imputation of atheism, and its unblushing inventions made his name with honest inquirers, such as Strabo, a byword for mendacity. Its main theory, however, was adopted by many eminent men, including Polybius, as well as by several of the Christian assailants of paganism—by Minucius Felix, Lactantius, and St Augustine, who found the ground ready prepared for them in their efforts to strip Zeus and the other pagan gods of the attributes of deity. Later Greek writers carried the theory still further, eliminating everything supernatural or extravagant, and leaving only a string of tales perfectly credible and commonplace. Æolus became an ancient mariner with a special knowledge of the winds, the Cyclopes a race of savages inhabiting Sicily, Atlas a great astronomer, and Scylla a fast-sailing pirate, as was also Pegasus, the winged horse of Bellerophon. Euhemerism was the favourite theory with the *soi-disant* philosophical historians of the 18th century in France, and the translation of Abbé Banier's great work, *The Mythology and Fables of Antiquity, explained from History* (Lond. 6 vols. 1739), extended it to England. To this school belong also writers such as Vossius, Bochart, and Huet. Herbert Spencer based religious emotions on primitive ancestor-worship, and explained totemism as due to nicknames, afterwards imbued with a sense of mystery. The historical school seeks the origin of gods in the practical experience and empirical thought of the Proto-Egyptians, the mysterious and supernatural being accretions. 'Osiris was regarded as an actual king who had died and been reanimated' (Elliot Smith).

Eulenspiegel, TILL, the prototype of all the knavish fools of later time, is said to have been born in the village of Kneitlingen, near Schöppenstadt, in Brunswick, about the end of the 13th century. His father was called Klaus Eulenspiegel, and his mother Anna Wortbeck. He was thrice baptised, in the font, in mud, having been dropped from his mother's arms, and finally in hot water, to cleanse him from the mud; he afterwards wandered over Europe, and had many comical adventures, and played many rough practical jokes and tricks on the people whom he met with. His tomb is shown at Mölln, about four leagues from Lübeck, where tradition makes him die about 1350; but the inhabitants of Damme, in Belgium, also boast of having his bones in their churchyard, and place his death in 1301. Many regard Eulenspiegel as an altogether imaginary person, whose name was used merely to father a cycle of medieval tricks and adventures; others argue that there were two historical individuals of that name, father and son, of whom the former died at Damme, and the latter at Mölln. The stories that circulate in Germany under Eulenspiegel's name were not collected, as the book containing them itself informs us, till after Eulenspiegel's death, and without doubt were originally written in the Low German

tongue; from Low German they were translated into High German. The book underwent considerable alterations at the hands of both Protestants and Catholics, who made it a vehicle for the expression of their own likes and dislikes. The oldest known edition is that printed at Strasburg in 1515, of which but one copy is known to exist—that in the British Museum (new ed. Halle, 1885). Another was issued in 1519, a new edition of which was edited by Lappenberg (Leip. 1854). The next impression, that of 1520-30, originated at Cologne (not in Lower Saxony), and was reproduced by photo-lithography at Berlin in 1865. A metrical version, *Der Eulenspiegel reimenweis*, was made by Fischart, and published at Frankfurt in 1571. For centuries it has been a favourite *Volksbuch*, not only in Germany, but in many other countries. Translations of it exist in Bohemian Polish, Italian, English (as a miracle play: *A merry Jest of a man that was called Howleglas*), Dutch, Danish, French, and Latin. Simrock modernised it (1878); works by Bottger (1850) and J. Wolff (1875) owe to it little beyond the name. De Coster made 'Thyll Uleenspiegel' a personification of Flanders. Hauptmann has written an epic; and on his 'pranks' Richard Strauss composed a notable orchestral piece. A version of the story is given in Roscoe's *German Novelists*: an English translation by K. R. H. Mackenzie appeared in 1890. It should be added that the Low German *Uleenspiegel* has nothing to do with owls or glasses. It became in French 'Ulespiègle,' whence the word *espiègle*.

Euler, LEONHARD, a distinguished mathematician, born 15th April 1707, at Basel, where he afterwards studied under John Bernoulli, and was the friend of Daniel and Nicholas Bernoulli. At the age of nineteen he was second in the contest for a prize offered by the Academy of Paris for the best treatise on the masting of ships. His friends the Bernoullis had been called to St Petersburg by Catharine I., when she founded the Academy, and in 1727 they induced Euler to settle in that capital, where in 1730 he was appointed to the chair of Physics, in 1733 of Mathematics. From that time he continued to labour in the field of mathematics with an ardour that excited the generous rivalry of the Bernoullis. More than half the mathematical treatises in the 26 quarto volumes published by the St Petersburg Academy from 1727 to 1783 are by Euler, and at his death he left more than 200 treatises in MS., which were afterwards published by the Academy. The French Academy of Sciences awarded him its prize on several occasions, and in 1740 his treatise on Tides shared the prize with those of Maclaurin and Daniel Bernoulli. In 1741 he accepted the invitation of Frederick the Great to Berlin, and there published a great number of valuable papers. In 1766 he returned to St Petersburg, where he died, September 18, 1783. The last years of his life were spent in total blindness, amid which he still pursued his researches, dictated his well-known *Introduction to Algebra* to his servant, and perfected, with some assistance, his theory of the moon's motion, constructing new tables, and carrying in his wonderful memory all the elaborate computations involved in his difficult task. After his return to St Petersburg, he also prepared his *Lettres à une Princesse d'Allemagne* (3 vols. 1768-72), in which, along with much theory unsoundly applied, there is a clear exposition of the most important facts in physics. Euler was of an upright, amiable, and religious character, and a man of wider general culture than might have been looked for in one who pursued his special studies so keenly. His proper domain was the abstruser parts of pure mathematics, and here his principal works include his Theory of Planetary Motion, Introduc-

tion to the Analysis of Infinities, Institutions of the Differential and of the Integral Calculus, and Dioptrics, which are all, as well as his *Opuscula Analytica*, in Latin. See Rudio's *Leonhard Euler* (Basel, 1884) and *Die Baseler Mathematiker* (ib. 1884); also the Basel edition of his *Opera Omnia* (1911 et seq.).

Eumenides (Gr., 'the benign'), the euphemistic name for the Erinyes, the Roman *Furæ* or *Divæ*, three fearful winged maidens who dwell in the depths of Tartarus, daughters of Earth or of Night, represented with serpents twined in their hair, and with blood dripping from their eyes, whose function as early as Homer and Hesiod is to punish men both in this world and after death for such crimes as perjury, murder, and the violation of filial duty and of the rite of hospitality. They were regarded also as goddesses of Fate, somewhat like the Moiræ or Fates, and they had a share in the grim providence which led the doomed ones into the way of calamity. A part of their function was also to hinder man from acquiring too much knowledge of the future. Their number is usually three, and their names Alecto, Megæra, and Tisiphone; but sometimes in the poets they appear as one, and we find a whole chorus of Erinyes in the tragedies of Æschylus. The later poets and sculptors represented them in the more pleasing form of winged virgins, attired in the garb of huntresses, bearing torches in their hands, and with a wreath of serpents round their heads. Gradually, they came to be considered goddesses of the infernal regions, who punished crimes after death, but seldom appeared on earth. In Athens their worship, which, like that of the other infernal deities, was conducted in silence, was held in great honour. The sacrifices offered to them were black sheep and libations of *nephalia*, honey mixed with water. The turtle-dove and the narcissus were sacred to them. They had a sanctuary in the vicinity of the Areopagus, and one at Colonus.

Eumolpus (the 'sweet singer'), in Greek Mythology, the son of Poseidon and Chione, was brought up in Ethiopia, whence he went to Thrace. Afterwards passing into Attica, at the head of a body of Thracians, to assist the Eleusinians in their war against Erechtheus, he and his sons were slain in battle. He was regarded as the founder of the Eleusinian mysteries. An illustrious Athenian family, the *Eumolpidae*, claimed descent from Eumolpus, and held the office of priests of Demeter in Eleusis.

Eunomius, the leader of an extreme sect of Arians, called after him Eunomians, was born at the village of Dacora, in Cappadocia. He attached himself to Aëtius, then at Alexandria, and became his disciple and associate. Through the influence of Eudoxius he became Bishop of Cyzicum about 360, but was compelled in a short time to resign his see, and after this he came forward as the leader of a party. His confession of faith, sent to Theodosius in 383, was rejected, and Eunomius was seized at Chalcedon, and sent first to Mœsia, then to Cappadocia, where he was still living in his native village in 392. According to Philostorgius, he was unhandsome, with white spots (Gr. *alpos*) on his face, and had a stammering tongue in spite of his eloquence. The doctrines of Eunomius and Aëtius, which were simply those of Arius carried to an extreme, were condemned at the second Œcumenical Council. After his death the Eunomians (who were also called Euxontians, Heterousiasts, and Anomeans) broke completely with the orthodox church. Their internal disunion quickly put an end to the party. His only extant writings are his two apologies and his confession.

See ARIUS, and the article by Loofs in the Hauck-Herzog, *Realencyklopædie* (1896-1909).

Eunuch (Gr. *eunouchos*, 'one who has charge of a bed'; *eunē*, 'a bed') is, etymologically, a man intrusted with the charge of women's apartments in the East; but the word means always a person who has been castrated, in order to serve in the harem. The barbarous custom of castrating men is usually an accompaniment of polygamy, and seems to have been earliest practised in Africa; but it established itself, along with Asiatic vices, in the Roman empire. At the Byzantine court the eunuchs often played an important rôle, and became so prominent in affairs of state that the word eunuch came practically to be the name of a great state-officer, the chamberlain. The Italian word *castrato* is that usually employed for a man who has as a youth suffered castration to prevent his voice from breaking. Such persons preserve the pure, clear, high timbre of the boy's voice, and add the grown man's lung power; and in spite of the canonical law and more than one papal bull, came to be highly prized in Italy for singing in churches, in the opera, and at concerts, and till of late were common. In the 18th century it was estimated that 4000 boys were yearly castrated for musical purposes. The castrati were at one time not unknown in France, Germany, and England, as connected with the Italian opera. Many—such as Farinelli (q.v.) and Caffarelli—were really great singers. See CASTRATION.

Euomphalus, a large genus of fossil gastropodous shells, characterised by its depressed and discoidal shell, with angled or coronated whorls, five-sided mouth, and very large umbilicus.

Eunymia is an extract from the bark and root-bark of the *Euonymus atropurpureus*, the Spindle Tree (q.v.), or Wahoo, a shrub indigenous to the United States. A mixture of a number of substances, it has long been used in America as a cholagogue, purgative and diuretic, and in Britain for its supposed stimulant action on the liver.

Eupatoria (formerly *Koslov*), a port on a bay in the west of the Crimea, 40 miles NW. of Simferopol. The principal building is the Tatar mosque, built in 1552. Eupatoria exports corn, hides, wool, and salt, and manufactures candles, soap, leather, and marine engines. Its shallow harbour is sheltered only from the north and north-east winds. There are brine and mud baths. Pop. 26,000 (Tatars, Karaite Jews, Armenians, and Greeks). The town was taken from the Tatars by the Russians in 1783, in September 1854 was occupied and fortified by a portion of the Anglo-French invading army, and in February 1855 was the scene of a Turkish defeat of the Russians.

Eupatorium, a large genus of Composite, allied to Coltsfoot (Tussilago) and Butter-bur (Petasites). The species are mostly tropical and temperate American, but *E. cannabinum* is the common Hemp

Hemp Agrimony
(*Eupatorium cannabinum*).

Agrimony of river-banks and marshy places, formerly reputed in domestic medicine. The roots of several American species are still so employed, notably Thorough-wort (*E. perfoliatum*) and *E. purpureum*. Their astringency gives several South American species a reputation in the treatment of wounds and snake-bites; and the Guaco, reckoned of almost universal efficacy in tropical America, is derived from the allied *Miliana guaco*. The roots of some are used in tanning, and others yield a variety of indigo.

Eupatrides, the first class of citizens in ancient Athens, corresponding to the Roman *optimates*, 'the aristocrats or nobles.' The second class was the *gēnōroī*; the third, the *dēmourgōi*. Like the Roman patricians, the eupatrides retained the priestly offices after the establishment of the democracy.

Eupen, a manufacturing town of Rhenish Prussia, ceded to Belgium in 1919, in a beautiful valley on the Vedre, and 12 miles by rail S. of Aix-la-Chapelle. It has flourishing woollen manufactures, besides dye-works, machine-shops, breweries, &c. It owes its prosperity chiefly to French refugees, who settled here after the peace of Lunéville (1801), which assigned it to France; in 1814 it came from Limburg to Prussia. Pop. 13,000, almost all Catholics and German-speaking.

Euphemism (Gr. *eu*, 'well,' and *phēmī*, 'I speak'), a figure of rhetoric by which an unpleasant or offensive matter is designated in indirect and milder terms. The ancient Greeks used a multitude of euphemisms, to avoid words that were thought to be ominous of evil, or offensive to the unseen powers. They spoke of the Eumenides, or 'benign goddesses,' instead of the Furies; just as the elves and fairies of more modern folklore used to be spoken of as 'good neighbours.' This instinct has done much to change the significations of words and impair the noble simplicity of our language, from a mawkish and purient nastiness which fondly imagines itself the mother of nice ideas.

Euphonium, a bass Saxhorn (q.v.).—The *Euphonon* was a variation of the Harmonica (q.v.), invented by Chladni in 1790.

Euphorbia, OIL OF, or OIL OF CAPER SPURGE, an extremely acrid fixed oil, obtained by expression, or by the aid of alcohol or ether, from the

Caper Spurge (*Euphorbia lathyris*).

seeds of the Caper Spurge (*Euphorbia lathyris*), a plant common in many parts of Europe, and naturalised in some places in Britain (see SPURGE).

Oil of euphorbia has much resemblance to croton-oil in its properties, although less powerful, and is sometimes used as a substitute for it, in doses of from three to ten drops. It is good for use only when recently extracted.

Euphorbiaceæ, a very extensive order of dicotyledons, containing some 4000 known species—trees, shrubs, and herbaceous plants, of the most extraordinarily varied, often cactus-like habit. They abound chiefly in warm countries, most of all in tropical America. The few found in the colder parts of the world are all herbaceous. The British species are different kinds of Spurge (Euphorbia) and Dog's Mercury (Mercurialis). The Euphorbiaceæ usually abound in an acrid and poisonous milky juice; although there are species of which the juice is bland or becomes so through the application of heat. The recognition that the peculiar 'flower' in Euphorbia, &c. is really a reduced inflorescence, is due to Robert Brown (see CYATHUM, SPURGE). Amongst those most remarkable for the acidity of their juice are the Manchineel (q.v.) and *Excoecaria agallocha*, an East Indian tree—formerly supposed to yield one of the kinds of aloes wood—the smoke from the burning of which is extremely dangerous to the eyes, and of which the juice sometimes blinds the woodcutter. Many of the Euphorbiaceæ are valued for their medicinal properties. Thus, the juice of some of the spurges, the roots of others, the bark of different species of Croton (Cascarilla Bark, Copalche Bark), &c. are used in medicine; and to plants of this order we are indebted for castor-oil, croton-oil, &c. A few of the Euphorbiaceæ yield fragrant balsamic products (see CROTON); a few, although their juice is poisonous, yield a wholesome starch in considerable abundance (see MANIOC); a few are cultivated and used as pot-herbs, particularly species of Plukenetia in the East Indies; a few yield wholesome and agreeable sub-acid fruits, as *Cicca disticha* and *C. racemosa* in the East Indies; the seeds of some are edible, as those of the Candle-nut (q.v.), &c.; the oil of the seeds is also in some cases used for food, like other bland oils, but more frequently for burning, as castor-oil, candle-nut oil, the oil of *Elæococca verrucosa* in Japan and Mauritius, and the solid oil of *Stillingia sebifera*, which is used in China for making candles, and in medical preparations as a substitute for lard. See TALLOW-TREE. Others yield dyestuffs. The timber of some is valuable—e.g. African Teak (q.v.). Many species are cultivated in gardens and hot-houses, more frequently for their curious appearance than for their beauty; but the large, deep crimson bracts of *Poinsettia pulcherrima*, a native of Mexico, make it a very attractive plant.

Euphorbium, an extremely acrid gum-resin, obtained from several species of Euphorbia or Spurge (q.v.), as *E. officinarum* and *E. antiquorum* in the north of Africa, Arabia, and the East Indies, and *E. Canariensis* in the Canary Islands. It is obtained by incisions in the branches, whence issues an irritating milky juice, which dries in the sun, and becomes a yellowish-gray, waxy gum-resin. The persons who collect it are obliged to defend their mouths and nostrils by a cloth, as its particles produce incessant sneezing, violent inflammation of the nostrils, and a very painful burning sensation in the mouth. On account of its excessive acidity its use is now almost entirely confined to veterinary medicine, although it is still occasionally mixed with Burgundy pitch or other substances to make rubefacient plasters for chronic affections of the joints; and its powder, mixed with much starch or flour, has been employed as an *errhine* in chronic affections of the eyes, ears, or brain. It was formerly administered as an emetic and drastic

purgative, but is dangerously violent in its action.

Euphrasy. See EYEBRIGHT.

Euphrates (Pers. *Ufratu*, Heb. *Phrat*, Syr. *Ephrat*, Arab. *Furat*) is the largest river in Western Asia, and, with the Tigris, forms the most important river-system of that part of the Continent. It has its source in the heart of Armenia in two branches—the Kara-su (270 miles) and the Murad (300 miles), of which the former rises a few miles N.E. of Erzerum, and the latter over 130 miles to the east, near Lake Van—uniting in about 39° N. lat. and 39° E. long., close to Keban Maadin (2664 feet above the sea). From here the united stream flows in a general southerly direction, and breaks through the Taurus in a succession of rapids and cataracts for about 40 miles, emerging at Sumeysát (the ancient *Samosata*), and passing Bir, at which point it is 100 miles distant from the nearest shore of the Mediterranean. Flowing south, it separates for a considerable distance Mesopotamia from Syria and the deserts of Syrian Arabia; then curving to the south-east, it flows on to Kurna, where it is joined by the waters of the Tigris; and the joint river, taking the name of the Shat-el-Arab, empties itself by several arms (only one of which is navigable by large vessels) into the Persian Gulf, 60 miles below Basra, after a course of fully 1700 miles. The principal of its few tributaries after leaving the mountains are the Sajur on the right, and the Balik-su and Khabúr on the left bank, besides the Persian river Karín, which enters the estuary at Mohammera. The chief towns now on its banks are Sumeysát, Bir, Ana, Hit, and Hilla, Basra lying really on a creek a short distance from the main stream; the river between Ana and Hit is studded with islands, many of them inhabited. The Euphrates is more or less navigable for light craft as far as Hit, and farther while the river is in flood (April to August). In ancient times, when canals and embankments regulated the river's inundations, these exercised the same beneficial effect over a fertile and populous country as those of the Nile on Egypt; but barely a hundredth of the old system is maintained to-day. Numerous remains of ancient cities are still to be traced near the banks, such as the famous site of Babylon, and the Birs Nimrud (see BABYLONIA). In 1908 Sir William Willcocks submitted to the Turkish government a scheme for irrigating some 3,000,000 acres in Mesopotamia, at a cost of £7,410,000, with every prospect of a highly remunerative return—to make another Egypt of Mesopotamia. In 1911 the government approved a much less extensive scheme, which would, however, restore fertility to a large area in the Euphrates Valley. It included the damming up of the head of the Euphrates canal, into which the main current of the river had for many years been diverted, with disastrous consequences for agriculture on the banks of the river and for such navigation by small craft and rafts as was formerly practicable.

It used to be debated which of the two ancient trade-routes to India—that by Suez, or the other by way of Scanderoon and down the Euphrates Valley—was to be preferred. Captain (afterwards General) F. R. Chesney, having, in 1831, descended the Euphrates, maintained that this was the shortest possible route to Bombay, with less open sea than any other, and that the country it would open out was rich in natural products. In 1835-36, with government support, Chesney conducted an expedition thither, which launched two iron steamers at Birejik, and though the channel was difficult, one steamer reached the mouth of the river, the other being lost in a violent storm. In 1856 he laid down a practicable route for a railway

by which the distance from England to Karachi was to be 1000 miles shorter than by the Suez route. Another scheme for a railway in 1862 also collapsed. In 1900-5 Sir W. Willcocks planned a railway from the Mediterranean by way of Damascus or Homs to Tadmor, thence to Hit, and so by the Euphrates Valley to Bagdad. The Bagdad railway, built under German auspices, which in the first decades of the 20th century became the key of the Nearer Eastern Question, is partly a Euphrates Valley line. In passing from Adana to Mosul on the Tigris it crosses the Euphrates at Jerablus, and runs for a long way across the Euphrates basin. From Mosul it passes by the Tigris Valley to Bagdad. The continuation from Bagdad to the Persian Gulf, with its branch to the Persian frontier at Khanakin, was a thorny political problem until the Eastern Question (q.v.) resolved itself into the Great War. Beyond Bagdad it returns to the Euphrates, and proceeds by Hilleh (with a branch to Kerbela) and Samawa to Basra. In 1919 the British authorities took over the administration of the railway.

Euphrosyne (i.e. 'the joyous one'), one of the Graces (q.v.).

Euphuism, a term used in English literature to denote an affected and bombastic style of language, fashionable for a short period at the court of Queen Elizabeth and in the literature of the time. The word was formed from the title of the book which brought the style into vogue, the *Euphues* of John Lyly (q.v.). Euphuism is usually taken to have been an exaggeration of the prevailing Italian taste; but Dr Landmann (*Der Euphuismus*, Giessen, 1881) has sought to prove that the peculiarities of Lyly's style are directly to be traced to Antonio de Guevara (1490-1545), Spanish court preacher, historiographer, bishop, and moralist. His chief work was an historical romance, based on the life and the meditations of Marcus Aurelius, one English translation of which by Lord Berners appeared in 1531, another by North (as *The Dial of Princes*) in 1558-67. Euphuism has even been called *Guevarism*. In Holofernes in *Love's Labour's Lost*, and in Sir Piercy Shafton in the *Monastery*, Euphuism is caricatured. See Underhill's *Spanish Literature in the England of the Tudors* (1900), but especially Feuillerat's *John Lyly* (1910).

Eupoda, a section of vegetarian beetles in the Tetramerous division. The gorgeous Kangaroo-beetles of tropical Asia and Africa, the Donacæ on water-plants, Crioceris on lilies, asparagus, &c. are examples. Comparatively few are British.

Eurasians is a convenient term for the offspring of Europeans and Asiatics, and is chiefly used in India of the children by European fathers of Hindu mothers and their descendants. They prefer to be called Anglo-Indians. The term Eurasian is also used in geography for facts true of Europe and Asia (Eurasia) taken as one continent, for the races common to both continents, or specifically for the primitive Aryan peoples.

Eure, a department of Normandy, immediately south of the department of Seine-Inférieure, contains an area of 2290 sq. m. Pop. (1881) 364,291; (1921) 303,159; the decrease has gone on steadily since 1846 (423,247), small families, often limited to one child, prevailing among all classes. The surface is generally level; the highest point reaches only 790 feet. The principal river is the Seine. The Eure, from which this department derives its name, and the Rille, both affluents of the Seine, are the only other important rivers; the Eure, which rises in the department of Oise, has a course of 141 miles, and is navigable for 54 miles. The climate is mild, moist, and foggy. Along the Seine the soil is in some parts sandy, stony, and

barren, but the greater part is very fertile. The chief natural products are corn, hemp, flax, vegetables, and fruit, particularly apples and pears, from which large quantities of cider and perry are made. The breeding of cattle, horses, and sheep is favoured by extensive meadows and pasture-lands. Iron is found in considerable quantities. There are extensive iron and copper works and pin-manufactories. Cotton goods, cloth, linen, paper, and beet-sugar also are manufactured. The department is divided into five arrondissements—Évreux, Louviers, Les Andelys, Bernay, and Pont-Audemer. The capital is Évreux.

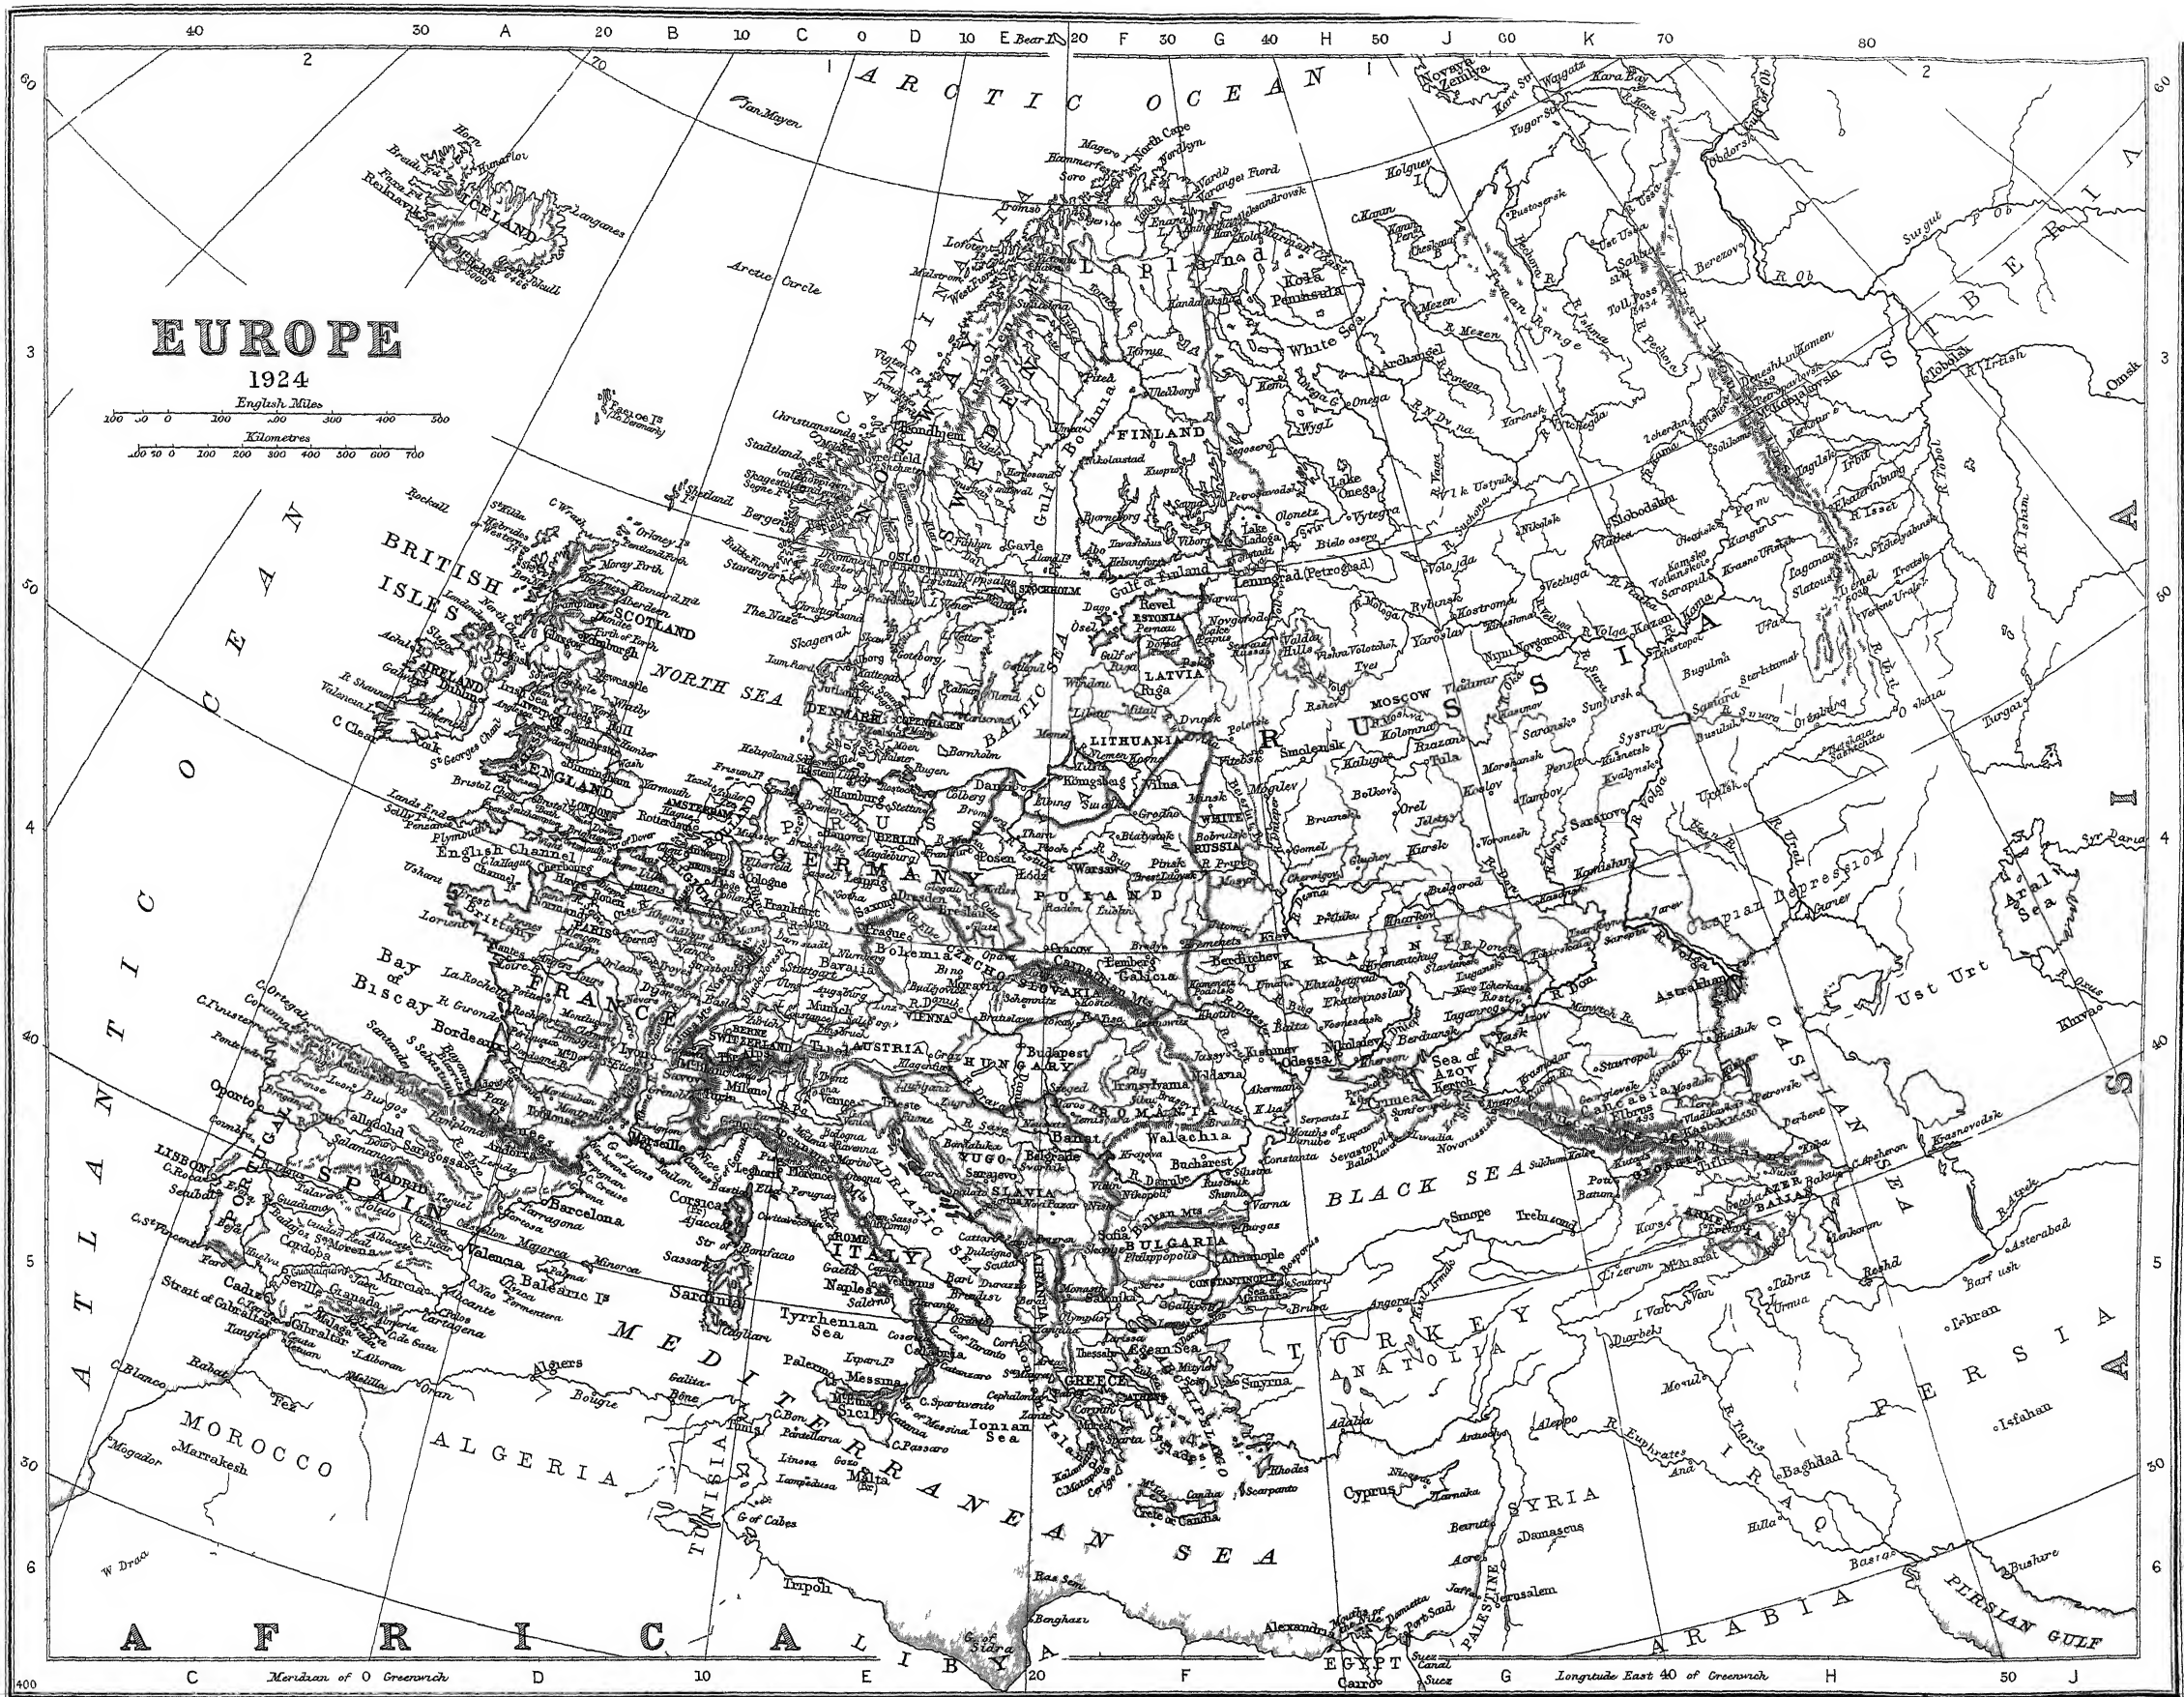

Eure-et-Loir, a department of France, to the south of the preceding, with an area of 2260 sq. m. Pop. (1872) 282,622; (1921) 251,255. It is watered mainly by the Eure in the north, and the Loir in the south. It is in general level, the east and south being occupied by high and extensive flats; while in the west the scenery is finely varied by wooded hills and valleys. The soil is fertile, and good crops of wheat and oats are raised, besides considerable quantities of vegetables and fruit; cider is prepared, and some wine. Stock-raising also is of importance, and iron and a few other minerals are worked. The rivers, though not navigable, furnish valuable water-power for the numerous mills on their banks; besides foundries, there are manufactories of beet-root sugar, cotton, wool, silk, paper, boots, and hats. The department is divided into the four arrondissements of Chartres, Châteaudun, Dreux, and Nogent-le-Rotrou, with the town of Chartres for capital.

Eureka, (1) a port and capital of Humboldt county, California, on Humboldt Bay, chiefly noteworthy for its mild, equable climate. It has several lumber-mills, and exports great quantities of redwood lumber from the giant forests around. Pop. 13,000.—(2) A mining-town, capital of Eureka county, Nevada, 90 miles by rail S. of the Palisades station on the Central Pacific Railroad. Here are gold, silver, and lead mines. Pop. 700.

Euripides, the latest of the three great Greek tragedians, was born at the time when the Persian attack upon the freedom of Greece was being repelled in a series of glorious victories; and this fact is expressed in the story that he was born 480 B.C. at Salamis, whither the Athenians had fled, and where the Persian fleet was defeated in that year. The first half of his life coincided with the growth of the Athenian empire, the second with its decline. Æschylus, the first of the three tragedians, a man of forty when Euripides was born, probably had died before Euripides produced his first play—at which time Sophocles had already been thirteen years before the public, and Aristophanes, the comedian, who was to be the constant opponent of Euripides, was not yet born. Euripides was the son of wealthy parents, who probably had made their fortune by trade, for Aristophanes (*Ach.* 478, *Ran.* 840) banter him on the subject with jests which would have been pointless had they not contained some truth. Tradition says that his father intended him to compete in the national athletic festivals of Greece; and this may account for Euripides' pronounced dislike of athletes (*Frag.* 284). He then took to painting, but, like Théophile Gautier, abandoned it for literature; and he has indeed the painter's eye for an effective situation. Tradition represents him as the friend of Socrates, and the pupil of Prodicus, Protagoras, and Anaxagoras; and he does more than once reproduce in his plays Anaxagoras' doctrine of the origin of all things from the wedlock of Earth and Air (cf. *Frag.* 836, 890, 935; *Ar. Ran.* 892). He is said to have been married twice, and to have had three sons. Scandal has been busy with

his wives, but there can be no truth in it, otherwise we should have heard of it from Aristophanes; and his reputation as a woman-hater is not confirmed by an impartial study of his plays. How many diamas he wrote we do not know, but the names and some fragments of about eighty are known to us, and of these eighty we possess eighteen complete. He won the tragic prize only five times, and he died 406 B.C. at the court of Archelaus, king of Macedonia. His habits were those of the scholar and the recluse. He was one of the first and the few private persons in Greece to possess a library (cf. *Hipp.* 452, 954; *Iph. A.* 798; *Alc.* 962; *Frag.* 629; *Ar. Ran.* 943, 1403). He took no such part in public life as did Æschylus and even Sophocles. In politics he was a moderate, approving of democracy (*Frag.* 628), but not of demagogues (*Hec.* 132, 254). His views of life on the whole were pessimistic: he did not share Aristophanes' romantic illusions as to the past, and the contemplation of the future could bring no comfort in an age when the doctrine of progress had not as yet been formulated. The immoralities of the accepted mythology shocked him as well as other thinkers; but his philosophy sufficed neither to shake off the old religion nor to reconcile him to it. The names and probable order of the surviving plays are: *Alcestis*, *Medea*, *Hippolytus*, *Hecuba*, *Andromache*, *Suppliants*, *Heracles*, *Troades*, *Helena*, *Phænissæ*, *Orestes*; the *Bacchæ* and *Iphigenia in Aulis* were put on the Athenian stage only after the author's death; and it is uncertain to what period belonged the *Ion*, *Hercules Furens*, *Iphigenia in Tauris*, *Electra*, and *Cyclops*, whilst it is doubtful whether the *Rhesus* is genuine. Whereas the characters in the plays of Æschylus and Sophocles had been heroic in their proportions and greater than life, Euripides set to work to be human. And in this we have the secret both of his success and of his failure: of his failure, because he made the mistake of imagining human life to be the same thing as everyday life; of his success, because in his treatment of everyday motives and emotions he was, 'with his droppings of warm tears,' the 'most tragic of the poets.' His skill as a playwright is of the highest order; he can construct plots which are exciting beyond anything attempted by his predecessors, and he has an unerring instinct for a 'situation.' But he has all the unscrupulousness of the practical playwright: in his consuming desire to get on to the situation as rapidly as possible, and to bring the curtain down sharp on it, he substitutes a bald prologue for a proper exposition, and, instead of working out the dénouement, makes a *Deus ex machina* cut the knot of the situation. For the sake of the same all-important consideration he will sacrifice consistency in character-drawing, and transgress all the bounds of artistic self-restraint. His popularity increased, indeed we might almost say began, after his death; his plays were 'revived' on the stage more frequently than those of Æschylus or Sophocles; they fill a much larger place in the mind of Aristotle, as appears from his *Poetics*, than those of the other two tragedians; and the number of his plays that have survived is greater than both theirs put together. And Euripides was a favourite with Theocritus, Virgil, Ovid, Horace, Milton, and Browning.

Notable critics of the text were Porson (1797), Elmsley (1813), G. Hermann (1838), Badham (1851), Weil (1890). There are complete texts by Dindorf (1870), Kirchhoff, Paley, Nauck, and Murray. Murray's poetic translations of many of the plays have been acted. A. S. Way's verse-translation of the whole (3 vols. 1894-98) are also admirable. Verrall, in *Euripides the Rationalist* (1895), asserts that Euripides wrote his plays deliberately (though not explicitly) to make the gods ridiculous and undermine popular faith in miracles. See also Norwood, *Riddle of the Bacchæ* (1908), Verrall, *The Bacchantes* (1911), Murray, *Euripides and his Age* (1913).

Euroclydon, in the Authorised Version, following the ordinary Greek text, was the tempestuous wind by which St Paul's ship was wrecked (Acts, xxvii. 14). The revised translation, taking the Greek reading *euraklyōn*, has *Euraquilo*, 'a north-easter.' This is sometimes identified with the Boia (q.v.).

Euro'pa, the daughter of the Phœnician king Agenor, whom Zeus, in the form of a bull, bore off to Crete, where she became the mother of Minos, Rhadamanthus, and Sarpedon.

Europe is historically and politically by far the most important of the five great divisions of the world, though Asia vastly exceeds it in population. Geographically it should be regarded rather as a peninsula of Asia, or as a portion of the great joint Eurasian continent; in regard to physical geography, fauna, and flora, it is difficult to draw a sharp line between Europe and Asia. On three sides Europe is bounded by sea—north by the Arctic Ocean, west by the Atlantic, south by the Mediterranean, Sea of Marmora, and Black Sea. But on the east the Urals, Ural River, and Caspian, though commonly assumed as the boundary towards Asia, do not mark a precise limit in respect of climate, flora, fauna, or physical conditions generally (see this discussed at ASIA); and actually the governments of Perm and Orenburg in Russia in Europe extend far beyond the Urals. Between the Caspian and the Black Sea, the ridge of the Caucasus seems a convenient dividing line between Europe and Asia, but the Manytch depression is really, from the geographical point of view, a more correct boundary; physically the whole of the Caucasus region is part of Asia (q.v.). It is more curious that North Africa and South Europe are very closely related in many respects, geological and biological. It has even been said that the mountains of Auvergne divide northern France more sharply from Provence than the Mediterranean does southern Provence from Morocco and Algeria. But in current usage Europe is bounded on three sides by sea, and elsewhere by the Kara River, the Ural Mountains, Ural River, the Caspian, and the Caucasus.

Various etymologies have been proposed for the name Europe. The old mythological one was that it was named from Europa (q.v.)—why, was not very clear. Another was that it came from Eurus, the south-east wind. A third, given by Hermann, notes that the name is first applied, not to the whole continent, but (in the Homeric Hymn to Apollo) to the mainland of Thrace, as distinguished from the Peloponnesus and the Greek islands, and suggests that Europe therefore means Broad Land (*eurus ops*, 'broad face'). Of late the tendency is to assume that the name was first given by Phœnician traders, and is from the word *erebh*, 'darkness'—i.e. the land of sunset, of the west. The area to which the name of Europe was applied grew with the extension of Greek geographical knowledge.

Europe has a total length from Cape St Vincent on the south-west to the mouth of the Kara River on the north-east of 3400 miles; and from North Cape in Norway to Cape Matapan, the southernmost point of Greece, a total breadth of 2400 miles. The continent of Europe, irrespective of islands, lies within 36° 20'—71° 10' N. lat., and 9° 30' W.—66° 30' E. long. Its area is estimated at 3,800,000 sq. m., being about a third of that of Africa, a fourth of that of America, and a fifth of that of Asia. It does not greatly exceed the total area of the United States. Its indented coast-line is more extensive in proportion to its size than that of any other great natural division of the globe, and is estimated to measure little less than 50,000 miles. This is caused by its great irregularity,

and the number of deep inlets and gulfs which penetrate its surface. It has a population of about 400,000,000, which gives an average of about 107 for every square mile.

The body of the European continent divides itself naturally into two great portions—the great plain in the north-east, and the highlands from near the centre towards the south-west, the mountainous peninsula of Scandinavia lying apart from either. (See the accompanying physical map of Europe.) The plain occupies about two-thirds (2,500,000 sq. m.) of the entire extent of the continent. It reaches from the eastern boundary of Europe, north to the shores of the Arctic Ocean, south to the Caucasus and the Black Sea, and westward over the whole extent of the continent; gradually, however, becoming narrower towards the west. In shape this plain resembles a triangle; its base rests on the eastern boundary, and it may be said to reach its apex on the shores of Holland. It separates the two mountain-systems of Europe—the Scandinavian system (highest summit 7566 feet) on the north, and on the south the system of southern Europe. The mass of the Alps, covering an area of nearly 100,000 sq. m., forms the centre of the mountain-system of southern and western Europe, and stretches down on four sides towards France, Germany, Hungary, and Italy; the highest summit being 15,732 feet. The other chief mountain-masses are the Carpathians (8343 feet) the Balkans (9750), the Apennines (9574), the Pyrenees (11,170), and the Sierra Nevada (11,660), and in Sicily, Etna (10,758). The highest inhabited spot in Europe is, since 1882, the observatory on Etna (9075 feet), nearly 1000 feet higher than the hospice of the Great St Bernard. See ALPS, APENNINES, BALKAN, CARPATHIANS, PYRENEES, &c.

Europe is surrounded by water on three sides. The White Sea comes in from the Arctic Ocean; the German Ocean and the Mediterranean from the Atlantic. The most important peninsulas are in the north Scandinavia, and in the south the Crimea, the Balkan peninsula (with Greece), Italy, and Spain. With the exception of Iceland, the islands cluster closely round the mainland, the chief being Great Britain, Ireland, Iceland, Nova Zembla, Sardinia, Corsica, Sicily, and Crete (Candia). The lakes of Europe are small as compared with those of Africa or America, the largest being Ladoga and Onega in Russia, and Wener in Sweden. The Volga (2400 miles), the Danube (1740), the Don (1125), the Kama (1050), the Petchora (1000), the Ural (800), and the Rhine (760) are the largest rivers of Europe.

The details of the geography of Europe are given under the names of its several political divisions, and of its lakes, rivers, and mountains.

Geology.—The oldest rocks of Europe—viz. the Archæan and Palæozoic—occupy the most continuous area in the northern part of the continent. Thus, they extend over all the Scandinavian peninsula, Finland, and a considerable portion of northern Russia. In western Europe they are likewise well developed, as in the British Islands, which (if we except the midlands, and the eastern and south-eastern parts of England) may be said to be mainly composed of Archæan and Palæozoic rocks. Similar rocks cover extensive areas in Brittany, in central France, and in the Iberian peninsula. In central Europe they occur for the most part in sporadic areas of limited extent, which upon a geological map look like islands surrounded by younger strata than themselves. One of the largest of those areas is that which stretches from the north of France through the Ardennes and southern Belgium into Rheinland, Westphalia, and Nassau. Another considerable tract occupies most of Bohemia, and smaller areas are met

with in most of the mountain-ranges of Germany and central Europe. Archæan and Palæozoic rocks likewise appear to form the nuclei of the Pyrenees, the Alps, and the Caucasus, while the Ural range is exclusively composed of such rocks. In the maritime regions of the Mediterranean, crystalline schists and Palæozoic strata are sparingly met with, as in southern and eastern Spain, in Sardinia, and Corsica. Considerable tracts of schistose rocks, however, extend through the Balkan peninsula, and appear in many of the islands of the Ægean, in southern Greece, southern Italy, &c. Having mentioned the main areas at which these oldest rocks appear at the surface, it is not necessary to refer to the distribution of the Mesozoic and Cainozoic strata, save in the most general terms. They are confined chiefly to the low grounds of the continent, although now and again, as in the Pyrenees, the Alps, and the Caucasus, they rise to great elevations. It may be added also that they enter into the composition of not a few other hilly regions, such as the Carpathians, the Apennines, the high grounds of Heizegovina, Albania, &c. Accumulations of Pleistocene and Recent age are met with alike in mountainous and lowland regions. They are developed most continuously in the low grounds of central Europe—extending from the borders of the North Sea across Germany far into Russia. They likewise form enormous tracts of flat land bordering on the Black Sea, the Sea of Azov, and the Caspian. The alluvial lands through which the great rivers of Europe flow belong to the same division of geological time, while the glacial deposits which form the under-soils throughout a large part of northern Europe, and which reappear in the mountain-valleys of more southern regions, are all likewise included amongst Pleistocene and Recent accumulations.

Geologists are not yet agreed as to the origin of the Archæan rocks, and it is altogether premature, therefore, to speculate upon the physical conditions of Europe at the period of their formation. They consist chiefly of metamorphic rocks, some of which can be proved to have been originally eruptive, some volcanic, and others, again, sedimentary.

Leaving the Archæan, we find that the next oldest strata are those which were accumulated during the Cambrian period, to which succeeded the Silurian, the Devonian and Old Red Sandstone, the Carboniferous, and the Permian periods—all represented by great thicknesses of strata, which overspread wide regions.

Now, at the beginning of the Cambrian period, we have evidence to show that the primeval ridge which was subsequently to become the continent of Europe was still largely under water, the dry land being massed chiefly in the north. At that distant date a broad land-surface extended from the Outer Hebrides north-eastwards through Scandinavia, Finland, and northern Russia. How much farther north and north-west of the present limits of Europe that ancient land may have spread we cannot tell, but it probably occupied wide regions which are now submerged in the shallow waters of the Arctic Ocean. In the north of Scotland a large inland sea or lake existed in Cambrian times, and there is some evidence to suggest that similar lacustrine conditions may have obtained in the Welsh area at the beginning of the period. South of the northern land lay a shallow sea covering all middle and southern Europe. That sea, however, was dotted here and there with a few islands of Archæan rocks, occupying the site of what are now some of the hills of middle Germany, such as the Riesengebirge, the Erzgebirge, the Fichtelgebirge, &c., and possibly some of the Archæan districts of France and the Iberian peninsula.

The succeeding period was one of eminently

marine conditions, the wide distribution of Silurian strata showing that, during the accumulation of these, enormous tracts of the present continent of Europe were overflowed by the sea. None of these deposits, however, is of truly oceanic origin. They appear for the most part to have been laid down in shallow seas, which here and there may have been moderately deep. During the formation of the Lower Silurian the whole of the British area, with the exception perhaps of some of the Archæan tracts of the north-west, seems to have been under water. The submergence had commenced in Cambrian times, and was continued up to the close of the Lower Silurian period. During this long-continued period of submergence volcanic activity manifested itself at various points—Great Britain and Ireland being represented at that time by groups of volcanic islands, scattered over the site of what is now Wales, and extending westward into the Irish region, and northward into the districts of Cumberland and south Ayrshire. Towards the close of the Lower Silurian period considerable earth-movements took place, which had the effect of increasing the amount of dry land, the most continuous mass or masses of which still occupied the northern and north-western part of the continent. In the beginning of Upper Silurian times a broad sea covered the major portion of middle and probably all southern Europe. Numerous islands, however, would seem to have existed in such regions as Wales, the various tracts of older Palæozoic and Archæan rocks of south Germany, &c. Many of these islands were partially, and some entirely, submerged before the close of Silurian times.

The next great period—that, namely, which witnessed the accumulation of the Devonian and Old Red Sandstone strata—was in some respects strongly contrasted to the preceding period. The Silurian rocks, as already mentioned, are eminently marine. The Old Red Sandstones, on the other hand, appear to have been accumulated chiefly in great lakes or inland seas, and they betoken therefore the former existence of extensive lands, while the contemporaneous Devonian strata are of marine origin. Towards the close of the Upper Silurian period, then, we know that considerable upheavals ensued in western and north-western Europe, and wide stretches of the Silurian seabottom were converted into dry land. The geographical distribution of the Devonian in Europe, and the relation of that system to the Silurian, show that the Devonian sea did not cover so broad an expanse as that of the Upper Silurian. The sea had shallowed, and the area of dry land had increased, when the Devonian strata began to accumulate. In trying to realise the conditions that obtained during the formation of the Devonian and Old Red Sandstone, we may picture to ourselves a time when the Atlantic extended eastwards over the south of England and the north-east of France, and occupied the major portion of central Europe, sweeping north-east into Russia, and how much farther we cannot tell. North of that sea stretched a wide land-surface, in the hollows of which lay great lakes or inland seas, which seem now and again to have had communication with the open ocean. It was in these lakes that the Old Red Sandstone was accumulated, while the Devonian or marine rocks were formed in the wide waters lying to the south. Submarine volcanoes were active at that time in Germany; and similarly in Scotland numerous volcanoes existed, such as those of the Sidlaw Hills and the Cheviots.

The Carboniferous system contains the record of a long and complex series of geographical changes, but the chief points of importance in the present rapid review may be very briefly summed up. In

the earlier part of the period marine conditions prevailed. Thus, we find evidence to show that the sea extended farther north than it did during the preceding Devonian period. During the formation of the mountain-limestone, a deep sea covered the major portion of Ireland and England, but shallowed off as it entered the Scottish area. A few rocky islets were all that represented Ireland and England at that time. Passing eastwards, the Carboniferous sea appears to have covered the low grounds of middle Europe and enormous tracts in Russia. The deepest part of the sea lay over the Anglo-Hibernian and Franco-Belgian areas; towards the east it became shallower. Probably the same sea swept over all southern Europe, but many islands may have diversified its surface, as in Brittany and central France, in Spain and Portugal, and in the various areas of older Palæozoic and Archæan rocks in central and south-east Europe. In the later stages of the Carboniferous period, the limits of the sea were much circumscribed, and wide continental conditions supervened. Enormous marshes, jungles, and forests now overspread the newly-formed lands. Another feature of the Carboniferous was the great number of volcanoes—submarine and subaerial—which were particularly abundant in Scotland, especially during the earlier stages of the period.

The rocks of the Permian period seem to have been deposited chiefly in closed basins. When, owing to the movement of elevation or upheaval which took place in late Carboniferous times, the carboniferous limestone sea had been drained away from extensive areas in central Europe, wide stretches of sea still covered certain considerable tracts. These, however, as time went on, were eventually cut off from the main ocean and converted into great salt lakes. Such inland seas overspread much of the low-lying tracts of Britain and middle Germany, and they also extended over a broad space in the north-east of Russia. It was in these seas that the Permian strata were accumulated. The period, it may be added, was marked by the reappearance of volcanic action in Scotland and Germany.

So far, then, as our present knowledge goes, that part of the European continent which was the earliest to be evolved lay towards the north-west and north. All through the Palæozoic era a land-surface would seem to have endured in that direction—a land-surface from the denudation or wearing down of which the marine sedimentary formations of the bordering regions were derived. But, when we reflect on the great thickness and horizontal extent of those sediments, we can hardly doubt that the primeval land must have had a much wider range towards the north and north-west than is the case with modern Europe. The lands from which the older Palæozoic marine sediments of the British Islands and Scandinavia were obtained must, for the most part, be now submerged. In later Palæozoic times land began to extend in the Spanish peninsula, northern France, and middle Europe, the denudation of which doubtless furnished materials for the elaboration of the contemporaneous strata of those regions. Southern Europe is so largely composed of Mesozoic and Cainozoic rocks that we can say very little as to the condition of that area in Palæozoic times, but the probabilities are that it continued for the most part under marine conditions. In few words, then, we may conclude that, while after Archæan times dry land prevailed in the north and north-west, marine conditions predominated farther south. Ever and anon, however, the sea vanished from wide regions in central Europe, and was replaced by terrestrial and lacustrine conditions. Further, as none of the Palæozoic marine

strata indicates a deep ocean, but all consist for the most part of accumulations formed at moderate depths, it follows that there must have been general subsidence of our area to allow of their successive deposition—a subsidence, however, which was frequently interrupted by long pauses, and sometimes by movements in the opposite direction.

The first period of the Mesozoic era—viz. the Triassic—was characterised by much the same kind of conditions as obtained towards the close of Palæozoic times. A large inland sea then covered a considerable portion of England, and seems to have extended north into the south of Scotland, and across the area of the Irish Sea into the north-east of Ireland. Another inland sea extended westward from the Thuringerwald across the Vosges into France, and stretched northwards from the confines of Switzerland over what are now the low grounds of Holland and northern Germany. In this ancient sea the Harz Mountains formed a rocky island. While terrestrial and lacustrine conditions thus obtained in central and northern Europe, an open sea existed in the more southerly regions of the continent. Towards the close of the period submergence ensued in the English and German areas, and the salt lakes became connected with the open sea.

During the Jurassic period the regions now occupied in Britain and Ireland by the older rocks appear to have been chiefly dry land. Scotland and Ireland, for the most part, stood above the sea-level, while nearly all England was under water—the hills of Cumberland and Westmorland, the Pennine chain, Wales, the heights of Devon and Cornwall, and a ridge of Palæozoic rocks which underlies London being the chief lands in south Britain. The same sea overflowed an extensive portion of what is now the continent. The older rocks in the north-west and north-east of France, and the central plateau of the same country, formed dry land; all the rest of that country was submerged. In like manner the sea covered much of eastern Spain. In middle Europe it overflowed nearly all the low grounds of north Germany, and extended far east into the heart of Russia. It occupied the site of the Jura Mountains, and passed eastward into Bohemia, while on the south side of the Alps it spread over a large part of Italy, extending eastwards so as to submerge a broad area in Austria, Hungary, and the Balkan peninsula. Thus the northern latitudes of Europe continued to be the site of the chief land-masses, what are now the central and southern portions of the continent being a great archipelago with numerous islands, large and small.

The Jurassic rocks, attaining as they do a thickness of several thousand feet, point to very considerable subsidence. The movement, however, was not continuous, but ever and anon was interrupted by pauses. Taken as a whole, the strata appear to have accumulated in a comparatively shallow sea, which, however, was sufficiently deep in places to allow of the growth, in clear water, of coral reefs.

Towards the close of the Jurassic period a movement of elevation ensued, which caused the sea to retreat from wide areas, and thus, when the Cretaceous period began, the British region was chiefly dry land. Middle Europe would seem also to have participated in this upward movement. Eventually, however, subsidence again ensued. Most of what are now the low grounds of Britain were submerged, the sea stretching eastwards over a vast region in middle Europe, as far as the slopes of the Urals. The deepest part of this sea, however, was in the west, and lay over England and

northern France. Farther east, in what are now Saxony and Bohemia, the waters were shallow, and gradually became silted up. In the Mediterranean basin a wide open sea existed, covering large sections of eastern Spain and southern France, overflowing the site of the Jura Mountains, drowning most of the Alpine lands, the Italian peninsula, the eastern borders of the Adriatic, and Greece. In short, there are good grounds for believing that the Cretaceous Mediterranean was not only much broader than the present sea, but that it extended into Asia, overwhelming vast regions there, and communicated with the Indian Ocean.

Summing up what we know of the principal geographical changes that took place during the Mesozoic era, we are impressed with the fact that, all through those changes, a wide land-surface persisted in the north and north-west of the European area, just as was the case in Palaeozoic times. The highest grounds were the Urals and the uplands of Scandinavia and Britain. In middle Europe the Pyrenees and the Alps were as yet inconsiderable heights, the loftiest lands being those of the Harz, the Riesengebirge, and other regions of Palaeozoic and Archæan rocks. The lower parts of England and the great plains of central Europe were sometimes submerged in the waters of a more or less continuous sea; but ever and anon elevation ensued, and the sea was divided, as it were, into a series of great lakes. In the south of Europe a Mediterranean sea would appear to have endured all through the Mesozoic era—a Mediterranean of considerably greater extent, however, than the present. Thus we see that the main features of our continent were already clearly outlined before the close of the Cretaceous period. The continental area then, as now, consisted of a wide belt of high ground in the north, extending roughly from south-west to north-east; south of this, a vast stretch of low grounds, sweeping from west to east up to the foot of the Urals, and bounded on the south by an irregular zone of land having approximately the same trend; still farther south, the maritime tracts of the Mediterranean basin. During periods of depression the low grounds of central Europe were invaded by the sea, the irregular zone of land lying immediately to the south was partially submerged, and so converted into groups of islands, and the Mediterranean at the same time extended north over many regions which are now dry land. It is in these two low-lying tracts, therefore, and the country immediately adjoining them, that the Mesozoic strata of Europe are chiefly developed.

A general movement of upheaval supervened at the close of the Cretaceous period, and the sea which, during that period, overflowed so much of middle Europe had largely disappeared before the beginning of Eocene times. The southern portions of the continent, however, were still mostly under water, while great bays and arms of the sea extended northwards now and again into central Europe. On to the close of the Miocene period, indeed, southern and south-eastern Europe consisted of a series of irregular straggling islands and peninsulas washed by the waters of a genial sea. Towards the close of early Cainozoic times, the Alps, which had hitherto been of small importance, were greatly upheaved, as were also the Pyrenees and the Carpathians. The floor of the Eocene sea in the Alpine region was ridged up for many thousands of feet, its deposits being folded, twisted, inverted, and metamorphosed. Another great elevation of the same area was effected after the Miocene period, the accumulations of that period now forming considerable mountains along the northern flanks of the Alpine chain. Notwith-

standing these gigantic elevations in south-central Europe—perhaps in consequence of them—the low-lying tracts of what is now southern Europe continued to be largely submerged, and even the middle regions of the continent were now and again occupied by broad lakes which sometimes communicated with the sea. In Miocene times, for example, an arm of the Mediterranean extended up the Rhone valley, and stretched across the north of Switzerland to the basin of the Danube. After the elevation of the Miocene strata, these inland stretches of sea disappeared, but the Mediterranean still overflowed wider areas in southern Europe than it does in our day. Eventually, however, in late Pliocene times, the bed of that sea experienced considerable elevation, newer Pliocene strata occurring in Sicily up to a height of 3000 feet at least. It was probably at or about that period that the Black Sea and the Sea of Azov retreated from the wide low grounds of southern Russia, and that the inland seas and lakes of central Europe finally vanished.

The Cainozoic era is distinguished in Europe for its volcanic phenomena. The grandest eruptions were those of the Eocene period. To that date belong the basalts of Antrim, Mull, Skye, the Faeroe Islands, and the older series of volcanic rocks in Iceland. These basalts speak to us of prodigious fissure eruptions, when molten rock welled up along the lines of great cracks in the earth's crust, flooding wide regions, and building up enormous plateaus, of which we now behold the merest fragments. The ancient volcanoes of central France, those of the Eifel country and many other places in Germany, and the volcanic rocks of Hungary are all of Cainozoic age; while, in the south of Europe, Etna, Vesuvius, and other Italian volcanoes date their origin to the later stages of the same great era.

Thus before the beginning of Pleistocene times all the main features of Europe had come into existence. Since the close of the Pliocene period there have been many great revolutions of climate; several very considerable oscillations of the sea-level have taken place, and the land has been subjected to powerful and long-continued erosion. But the greater contours of the surface which began to appear in Palaeozoic times, and which in Mesozoic times were more strongly pronounced, had been fully evolved by the close of the Pliocene period. The most remarkable geographical changes which have taken place since then have been successive elevations and depressions, in consequence of which the area of the continent has been alternately increased and diminished. At a time well within the human period the British Islands have been united to themselves and the continent, and the dry land has extended north-west and north, so as to include Spitz-bergen, the Faeroe Islands, and perhaps Iceland. On the other hand, the British Islands have been within a recent period largely submerged.

The general conclusion, then, to which we are led by a review of the greater geographical changes through which the European continent has passed is simply this—that the substructure upon which all the sedimentary strata repose is of primeval antiquity. The dry lands are built up of rocks which have been accumulated over the surface of a great wrinkle of the earth's crust. There have been endless movements of elevation and depression, causing minor deformations, as it were, of that wrinkle, and inducing constant changes in the distribution of land and water; but no part of the continental ridge has ever been depressed to an abysmal depth. The ridge has endured through all geological time. We can see also that the land has been evolved according to a definite plan.

Certain marked features begin to appear very early in Palaeozoic times, and become more and more pronounced as the ages roll on. All the countless oscillations of level, all the myriad changes in the distribution of land and water, all the earthquake disturbances and volcanic eruptions—in a word, all the complex mutations to which the geological record bears witness—have had for their end the completion of one grand design.

Climate, Flora, and Fauna.—In respect of climate, by far the greater portion of the area of Europe belongs to the northern section of the temperate zone, though parts of Norway, Sweden, Finland, and Russia lie within the Arctic Circle. The southern parts of Spain, Sicily, and Greece are some twelve degrees from the northern tropic. See CLIMATE, RAIN, TEMPERATURE.

The natural history of Europe very much agrees with that of the corresponding latitudes of Asia. The natural history of the European countries on the Mediterranean Sea is very similar to that of Asia Minor and of North Africa. The natural history of the more northern regions of Europe resembles that of the great plains of Central Asia and Siberia. The most northern regions have the strictly arctic flora and fauna common in a great measure to all the arctic and sub-arctic regions; whilst the natural history of the most southern countries assumes a subtropical character.

The temperature of the western and northern parts of Europe being raised by the Gulf Stream and the winds from the great mass of dry and desert land in Africa above what is elsewhere found in similar latitudes, the flora and fauna exhibit a corresponding character, affected, however, by the great amount of moisture derived from the Atlantic Ocean, and also to a still greater degree by the comparative uniformity of temperature which the proximity of the ocean produces. The effect of the last-mentioned causes is so great that the northern limit of some plants is sooner reached on the shores of the Atlantic than in the more central parts of Europe, where the winters are much colder, and the average temperature of the year is lower. Of this the vine and maize are notable examples. Plants which require a mild winter will not grow in the north—and scarcely even in the centre of Europe—but they advance along the western coast under the influence of the maritime climate. Thus, the myrtle—although not indigenous—grows even in the south of England. Amongst plants the date palm, and amongst animals a species of ape, are found in the south of Europe (the ape only on the Rock of Gibraltar); whilst some strictly African birds are frequent visitants, and many birds—as the cuckoo, swallow, &c.—are common to Europe and Africa, inhabitants in summer even of very northern regions, and returning in winter to the warm south.

Of the plants now most commonly associated in our thoughts with the southern countries of Europe, many have probably been introduced from Africa or from the East. This has probably been the case even with the myrtle, and certainly has been the case with the vine, the olive, the orange, lemon, &c., the fig, the peach, the almond, the apricot, &c. Some of the most extensively cultivated fruits are certainly indigenous to Europe, as the apple, pear, plum, and cherry, although even of these the first improved varieties may have been introduced from the earlier seats of civilisation in the East. Among the wild animals of Europe at the present day, the bison is still reckoned; and the ox existed at no very remote period in a truly wild state. The reindeer inhabits the extreme north of Europe; the elk, the stag, the fallow-deer, and the roebuck are found in more southern regions; the ibex or bouquetin exists on the high central moun-

tains; two species of antelope—the chamois of the Alps, and the saiga of the Russian plains—connect the European fauna with the Asiatic and African. Of mammals peculiar to this part of the palæarctic region, the most notable are the chamois, the musk rat, the fallow-deer, the civet, ichneumon, and porcupine. Of carnivorous animals, the most worthy of notice are the bear, the wolf, the fox, and the lynx. On this head see the article GEOGRAPHICAL DISTRIBUTION, and the sections on animal and vegetable life in the articles on the various countries. The European seas afford valuable fisheries, particularly of herring and of cod in the north, and of tunny, anchovy, &c. in the Mediterranean.

Ethnology.—In very early times Europe was inhabited by races differing very greatly from any existing variety of man, as is proved by the Heidelberg or Mauer jaw and the Piltdown remains (see EOANTHROPUS). To Mousterian times belongs the widespread race of Neanderthal (q.v.), probably without descendants at the present day. In the Aurignacian appear types that are not merely human as we understand the term, but might pass unnoticed among modern Europeans, if we may judge from their skeletons, while their art shows a development of mind to a very high level indeed. Anthropologists recognise survivals of these types in secluded corners of Europe. Both the Cro-Magnon and the Brunn-Brux or Combe Capelle type can be seen to-day in the Dordogne district; while the 'negroid' Grimaldi is seen in the slums of Mediterranean towns. The Cro-Magnon type is dysharmonic—long-skulled but short-faced—with low eye-sockets, very strong jaws and cheek-bones, and narrow nose. The name is sometimes used in a generalised way for types diverging somewhat from that of the 'old man of Cro-Magnon.' The other two races had 'high-ridged, long, narrow skull, strong cheek-bones, low, broad orbits, broad nose;' but while the Brunn race had 'strongly marked glabella and brow-ridges, and moderately projecting upper jaw,' the Grimaldi had 'weak glabella and brow-ridges, but very strongly projecting upper jaw' (Professor Fleure). These Aurignacians may have entered Europe from Africa or Asia as the ice retreated. With the Neolithic civilisation, and to some extent a little earlier, new types appear. The broad-headed Alpine people spread westwards through the mountain regions, probably from Asia Minor. Long-heads continue to north and south of the Alpine wedge. The Alpine type, as seen to-day, has usually brown hair and eyes, pallid skin, and thickest body. It includes most of the French, the South Germans, many of the Slavonic-speaking and Balkan peoples. The dark Mediterranean and the fair Nordic long-heads, whatever their origin—new-comers or modified descendants of the older inhabitants—meet in Britain, where intermediate varieties abound, either mixed or not yet differentiated. In addition to these, there are 'Mongolian' broad-heads in the north of Europe. While the general distribution seems to be very much as it was in Neolithic times, there is much encroachment of one race upon another, and secondary races may have arisen by crossing.

Language.—Of about sixty languages spoken in Europe, the most isolated is that of the Basques (q.v.). Of Semitic tongues there is only Maltese, unless Hebrew be reckoned, which survives in religious use. Finno-Tatar tongues are spoken by the Finns and their kindred in northern and eastern Europe (see FINLAND), by the Kalmuks, the Magyars, and the Turks. If the Caucasus be included the diversity is much greater; otherwise there remain only Indo-Germanic languages—Germanic, Letto-Lithuanian, Slavonic, Celtic, Italic, Albanian, Greek, and Gypsy. In central and south-eastern Europe the language-map resembles a mosaic.

Historical Geography.—The historical geography of the parts of Europe known in the oldest times is treated in the articles **ROME**, **BYZANTINE EMPIRE**, **GREECE**, &c. In the articles on the various countries of Europe (**FRANCE**, **GERMANY**, **AUSTRIA**, &c.) will be found detailed accounts of the origin and development of the several nations and countries; or in some cases (**BURGUNDY**, **NAVARRÉ**) of their gradual disappearance as separate states.

In this place it seems desirable to give a sketch of some of the most notable changes in the political distribution and national divisions in the European area since the fall of the Roman empire, and to indicate the outstanding features of the political geography of Europe at the important periods illustrated in the accompanying historical maps.

On the death of the Emperor Theodosius (395), the Roman empire was finally divided into two

STATE	FORM OF GOVERNMENT	Area Square Miles	Population.
Albania	Till 1912 Turkish; kingdom, 1914; under a supreme council (four members) and one chamber, republic 1925	14,000-15,000	881,877
Andorra	Republic, under suzerainty of France and Bishop of Urgel	191	5,281
Austria	Till 1918 limited monarchy (empire), forming dual monarchy with Hungary; now separate federal republic; area much reduced, 1919	32,352	6,428,386
Belgium	Limited monarchy	11,752	7,462,455
Bulgaria	Till 1908 principality tributary to Turkey; now kingdom (one chamber); area extended, 1918; curtailed, 1918, 1919	39,841	4,909,700
Czechoslovakia	Republic formed 1918-20 out of Austria and Hungary	54,241	18,610,405
Danzig	Till 1918 Prussian; now free city under League of Nations	754	865,000
Denmark	Kingdom (two chambers); North Slesvig added from Germany. See Iceland, below	17,144	3,289,105
Estonia	Till 1918 Russian; now republic (one chamber)	16,955	1,109,479
Finland	Till 1917 grand-duchy under the Tsar; republic, 1919 (one chamber)	132,510	3,366,507
France	Republic, Alsace-Lorraine added, 1918	212,659	39,209,618
Germany	Till 1918 limited monarchy (empire); now federal republic; area curtailed, 1918	182,271	59,858,284
Greece (in Europe)	Till 1924 limited monarchy (one chamber); now republic; area greatly extended, 1918, 1919	41,900	4,900,641
Hungary	Till 1918 limited monarchy (kingdom) forming dual monarchy with Austria; republic 1918-1920; kingdom (without a king), 1920; area greatly curtailed 1920	85,790	7,945,878
Iceland	Kingdom (two chambers); recognised as a sovereign state, 1918; connected with Denmark only by king and provisional arrangements	39,709	94,679
Italy	Kingdom (two chambers); area extended at Austria's expense, 1919; Fiume (free city, 1920) added, 1924	117,982	38,835,941
Latvia (Latvia)	Till 1918 Russian, now republic (one chamber)	25,000	1,850,622
Liechtenstein	Principality (one chamber)	65	10,716
Lithuania	Till 1918 Russian, now republic; Vilna seized by Poles; Memel added, 1923	42,686	2,586,570
Luxemburg	Grand-duchy (one chamber)	909	283,824
Monaco	Principality; absolute till 1911; now one chamber	8	22,956
Netherlands	Kingdom (two chambers)	13,205	6,365,814
Norway	Kingdom (two chambers elected as one); in personal union with Sweden till 1905	124,964	2,649,775
Spitzbergen	Under Norwegian sovereignty, 1923; part of kingdom, 1925	25,000	1,000
Jan Mayen	Annexed, 1920	160	Uninhabited.
Poland	Republic (two chambers) formed in 1918 out of Russia, Germany, and Austria; extended by seizure from Lithuania and conquest from Russia, 1920-21	146,821	27,092,025
Portugal	Till 1911 limited monarchy; now republic (two chambers)	35,490	5,957,965
Romania	Kingdom (two chambers); part of Dobruđa added, 1918; Bessarabia, Bukovina, Transylvania, &c., 1918	122,282	17,893,140
Russia (in Europe)	Till 1905 absolute monarchy (empire), then more or less limited; republic, 1917; soviet federal republic; area curtailed since 1918	1,488,240	93,867,923
San Marino	Republic	38	12,027
Spain	Kingdom (two chambers)	194,800	21,847,835
Sweden	Kingdom (two chambers); in personal union with Norway till 1905	173,035	5,904,489
Switzerland	Federal republic	15,975	8,880,820
Turkey (in Europe)	Till 1923 empire (constitution from 1908); now republic; area much curtailed since 1918	10,882	1,891,000
United Kingdom	Kingdom (two chambers)	95,041	44,167,913
Irish Free State	Since 1921-2 'a co-equal member of the community of nations forming the British Commonwealth of Nations'	26,592	3,139,688
Malta	Constitution granted, 1921	118	228,741
Gibraltar	Crown colony	2	20,638
Yugoslavia (kingdom of the Serbs, Croats, and Slovenes)	Kingdom (one chamber) formed in 1918 by the union of Serbia (kingdom; extended, 1918), Montenegro (principality till 1908; kingdom; extended, 1918), Bosnia-Herzegovina (Turkish province administered, and in 1908 annexed by Austria-Hungary), and various Austrian and Hungarian territories; with additions from Bulgaria, 1919	96,184	12,017,823

parts—the Latin empire, or Empire of the West, the capital of which was Rome; and the Greek empire, or Empire of the East, the capital of which was Constantinople. The Latin empire consisted of six dioceses—Italy, Gaul, Britain, Spain, Western Illyricum, and Africa; the Greek empire consisted of seven dioceses—the East, Egypt, Asia, Pontus, Thrace, Macedonia, and Dacia. In some of these dioceses may be traced the outlines of modern European countries.

Beyond the pale of the organised society of the Roman world lay a great barbaric society, divided into two parts—the German or Teutonic half geographically adjoining the Western empire, and the Slavonic or Scythian half adjoining the Eastern empire. The German barbarians were divided into a number of tribes and nations—Goths, Burgundians, Alemanni, Vandals, Longobards, Franks, Angles, Saxons, &c. Farther away were the nomadic Alans. The Slavs, the an-

cestors of the modern Russians, Poles, and others, had their seats still farther east, and took less share in the events of medieval history. In the destruction which preceded the resurrection of modern European society, it was chiefly the western or Latin half of the Roman empire that was involved, and the destruction was effected by the irruption chiefly of German nations; it is mainly the Germanic peoples who have created the modern nations of Europe. Amongst the Germanic peoples the Goths were most prominent (see *GOTHS*). The Gothic tribes were located, at the period when the movement began, in the extensive tract between the Vistula, the Danube, the Black Sea, and the Don, and were divided into Visigoths or Western Goths, and Ostrogoths or Eastern Goths.

The determining cause of the precipitation of the German races on the Latin empire was, it is well known, the sudden invasion of Europe (375 A.D.) by the Turanian or Ugrian nation of the Huns. Their movement was perhaps ultimately due to the gradual desiccation of the plateaus of Central Asia (see *ASIA*). Subduing the Slavonic region of Europe, and establishing there a Hunnish empire, which superseded that of its previous conquerors the Goths, these fearful Asiatic invaders produced a violent agitation among the Germanic peoples, and pressed them westward—Goths, Vandals, Burgundians, Suevi, Alemanni, Franks, Angles, and Saxons, all together. The agitations produced in Europe by the Huns, and by the consequent irruptions of the Germanic nations, sometimes in confederacy, and sometimes singly, into the provinces of the Western empire, were protracted over a whole century. It will be sufficient here to mention generally that the diocese of Gaul was overrun chiefly by Visigoths, Burgundians, and Franks; Spain, by Vandals, Suevi, and Visigoths; Africa, by Vandals crossing over from Spain; in Italy, successive invasions had left among the feeble native Italians a deposit of Visigoths, Vandals, Huns, &c.; Britain, abandoned by its Roman garrison as early as 410, had become a prey to the Angles and Saxons.

As soon as this intermixture of the two societies—the Roman or civilised, and the Germanic or barbarian—had taken place, they began to act upon each other. Modern society, in short, is the perfected result of the incorporation of Roman with barbaric society; and it derives ingredients from both. From the barbarians were derived the love of personal liberty and the sense of individual independence. From the Romans, on the other hand, were derived the forms of a regular and long-established civilisation. But more efficient still, as a means of acting on the barbarian conquerors, was the great institute of the Christian Church.

In the 6th century the Franks occupied northern France and part of central Germany; the West Goths, France south of the Loire; Burgundians, the valleys of the Rhone and the Saône and various adjoining territories; while the West Goths were dominant over most of Spain, the Suevi holding the rest. The Thuringians were established in Thuringia; the Saxons in the large territory between the Meuse in the west and the Oder in the east; the Danes and other Scandinavians in the region they still hold. The Ostrogoths held southern Europe from the Burgundian borders to the Danube, and the whole of Italy—which, however, in the latter part of the century, was occupied by the Lombards (see *ITALY*). The Slavonic Czechs were already in Bohemia; and the Bulgarians were between the Dnieper and the Danube.

In the latter part of the 8th century (see the first of the historical maps) the Frankish empire of Charle-

magne extended from the Ebro to the Elbe, and from the North Sea to Rome, the Franks having conquered both the Goths of France and the Burgundians. The Frankish empire was repeatedly divided and reunited; but ultimately the two great divisions of Neustria (the kingdom of the West Franks) and Austrasia (the kingdom of the East Franks—*Francia*, and not at all corresponding to what was later known as Austria) became the nuclei of the kingdoms and nations of France and of Germany.

In what is now Hungary were the Avars; while to the east of the northern portion of the Frankish realms was the region of Slavonia, including Bohemians, Poles, and other Slavic peoples. East of them again were that peculiar people the Khazari or Chazars (q.v.), belonging to the Finnic stock. Of the Gothic power in Spain nought was left but the little kingdom of Asturia; the rest formed the Moslem sultanate of Cordova, the Mohammedans having established themselves in Spain in 711. Most of England and part of Scotland was now occupied by the English or Anglo-Saxons. The Eastern empire had greatly shrunk.

In the 12th century (see Map II.) the kingdom of the East Franks had become the representative and successor of the Western empire, and, as the Germanic or Holy Roman empire, extended from the North Sea to the States of the Church, by this time the dominion of the popes. In the empire were the dukedoms or territories of Lotharingia or Lorraine, Francia, Swabia, Bavaria, Thuringia, Bohemia, Austria, and Burgundy (the latter lately an independent kingdom). In South Italy was the Norman kingdom of Sicily. Henry II. of Anjou, king of England, was lord of Normandy, Anjou, Brittany, and Aquitaine or Guyenne; the remainder of France being the kingdom of the successor of the kings of the West Franks. The power of the English kings was more fully established in Guyenne than in Anjou, and Guyenne remained much longer a part of the English dominions in France. England had established her power over the eastern part of Ireland. In Spain the Christian kingdoms of Leon, Castile, and Aragon were growing at the expense of the sultanate of Cordova. Poland and Russia were consolidated states, with heathen Prussians and Lithuanians for their northern neighbours. The Hungarians were in their present dominions; Bulgaria and Serbia still limited the decreasing Eastern empire on the north, while the latter was threatened on the east by the dreaded Turks.

At the Reformation in the 16th century Charles V. was not merely emperor in Germany, but king of Spain (whence the Moslems, long confined to Granada, had been driven), Sardinia, Sicily, and Naples, and ruler of the Netherlands and of the county of Burgundy. From the 15th century onwards, the imperial crown remained with the Hapsburgs. Ferdinand I., Archduke of Austria (and, after the abdication of his brother Charles V., emperor), obtained by marriage Silesia, Bohemia, and Hungary (as much of it as was not Turkish). These all became, like the archduchy and connected territories, hereditary domains of the House of Hapsburg; but while Bohemia, like the archduchy, was a fief of the empire, Hungary, with its dependencies, was no part of the empire at all. From the middle of the century till near the end of the 17th, the Hapsburgs held the northwest part of Hungary; while the Turks, who had wiped out the Eastern empire, occupied the rest, a pasha ruling at Buda. Transylvania, Moldavia, and Wallachia were three tributary principalities. Dalmatia long fluctuated between Venice and Hungary. At the peace of Westphalia in 1648 (see Map III.), which closed the Thirty Years' War, the power of the empire was weakened,

while that of France had increased, part of Alsace being given to France. By the 15th century France had acquired most of the territory of the old kingdom of Burgundy (between the Alps, the Saône, and the Mediterranean). It had absorbed the duchy of Burgundy (afterwards the French province of Burgundy or Bourgogne) in 1477; but it was not till 1674 that France seized the county of Burgundy (afterwards the French province of Franche Comté), and Strasburg and its territory in 1681. Avignon had become a papal possession in 1348, and did not become French till 1791. The duchy of Savoy was becoming more and more an Italian power. Spain still held the Spanish Netherlands and great part of Italy. The Protestant Netherlands and Switzerland were become independent states. Sweden had acquired territories from Germany, Poland, and Russia, and was one of the great powers. She held not merely Finland, but all the lands around the Gulf of Riga, including Esthonia and Lettland (Latvia). Sweden also held western Pomerania, Wismar, Bremen, and Verden, not as Swedish territory, but as fiefs of the empire; the ancient possessions of Denmark in the northern peninsula were acquired by Sweden in 1658. The duchy of Prussia had become independent of Poland in 1647. Poland, which early in the 16th century had been one of the most powerful states of Europe, holding under its sway a great part of Russia, now lost in power and territory, while Russia steadily grew. Turkey held part of the former dominions of the Eastern empire, the Austrian princes the rest. Venice was the most important native Italian power. Genoa held Corsica till 1768.

Before the outbreak of the French Revolution, Poland had ceased to exist as a state. Prussia had risen to greatness, and Russia had been greatly aggrandised. Sweden had fallen from her temporary hegemony of northern Europe. The Spanish Netherlands had belonged since 1713 to the House of Austria; French Bourbons held those parts of Italy that had been Spanish. The French Revolution began a series of changes in the distribution of power which culminated in the extension of Napoleon's empire over all Germany west of the Rhine, and great parts of northern Germany, the Netherlands, and most of Italy (see Map IV.); a portion being directly incorporated with the empire, another separately held by Napoleon himself as his kingdom of Italy, whilst his brother-in-law was king of Naples and his brother king of Spain. After the fall of the empire, France retired within her old limits; the minor German princes constituted their states in a loose confederation, and of this Austria assumed the presidency. Italy was parcelled out amongst numerous despotic princes, and the Venetian dominions became Austrian. The Netherlands became once more a kingdom, ultimately separated into Holland and Belgium.

Later changes on the map have been the consolidation of Germany as an empire, under the headship of Prussia, and the restitution to it of Alsace-Lorraine; the retirement of Austria out of Germany, and her absorption of Bosnia and Herzegovina; the unification of Italy as a kingdom; the gradual diminution of Turkish territory by the independence and growth of Greece, Rumania, Serbia, Montenegro, Bulgaria, and Albania; the separation of Norway and Sweden, and of Denmark and Iceland. The war of 1914-18 and the revolutions associated with it have given independence to Czechoslovakia, Poland, Lithuania, Lettland, Esthonia, separated Austria from Hungary, Finland from Russia, assigned much of the territory of the defeated states (as Alsace-Lorraine, North Schleswig, Transylvania, part of Tyrol) to their neighbours, and united the Southern Slavs.

See the *Historical Geography of Europe*, by E. G. Freeman (2 vols. 1881), his *General Sketch of European History* (2d ed. 1876), *Primer of History of Europe* (1876), and *Chief Points of European History* (1886); T. H. Dyer, *History of Modern Europe, 1453-1871* (new ed. 6 vols. 1901-7); C. A. Fyffe, *A History of Modern Europe, 1792-1878* (3 vols. 1884-90); G. P. For Ethnology and Archæology, see the works of Beddoe, Ripley, Sergi, Déchelette, Burkiit, Boule, Macalister, Fleury.

Eurotas (mod. *Irt*), one of the chief rivers of the Peloponnesus, flows south through Laconia, past Sparta to the Gulf of Gythion. Its course is about fifty miles in length, but it is not navigable.

Euryalë, a genus of Water-lilies, closely allied to *Victoria* (q.v.), but with small flowers. Seeds and root-stock of *E. ferox* are eaten, and the plant is cultivated in China.

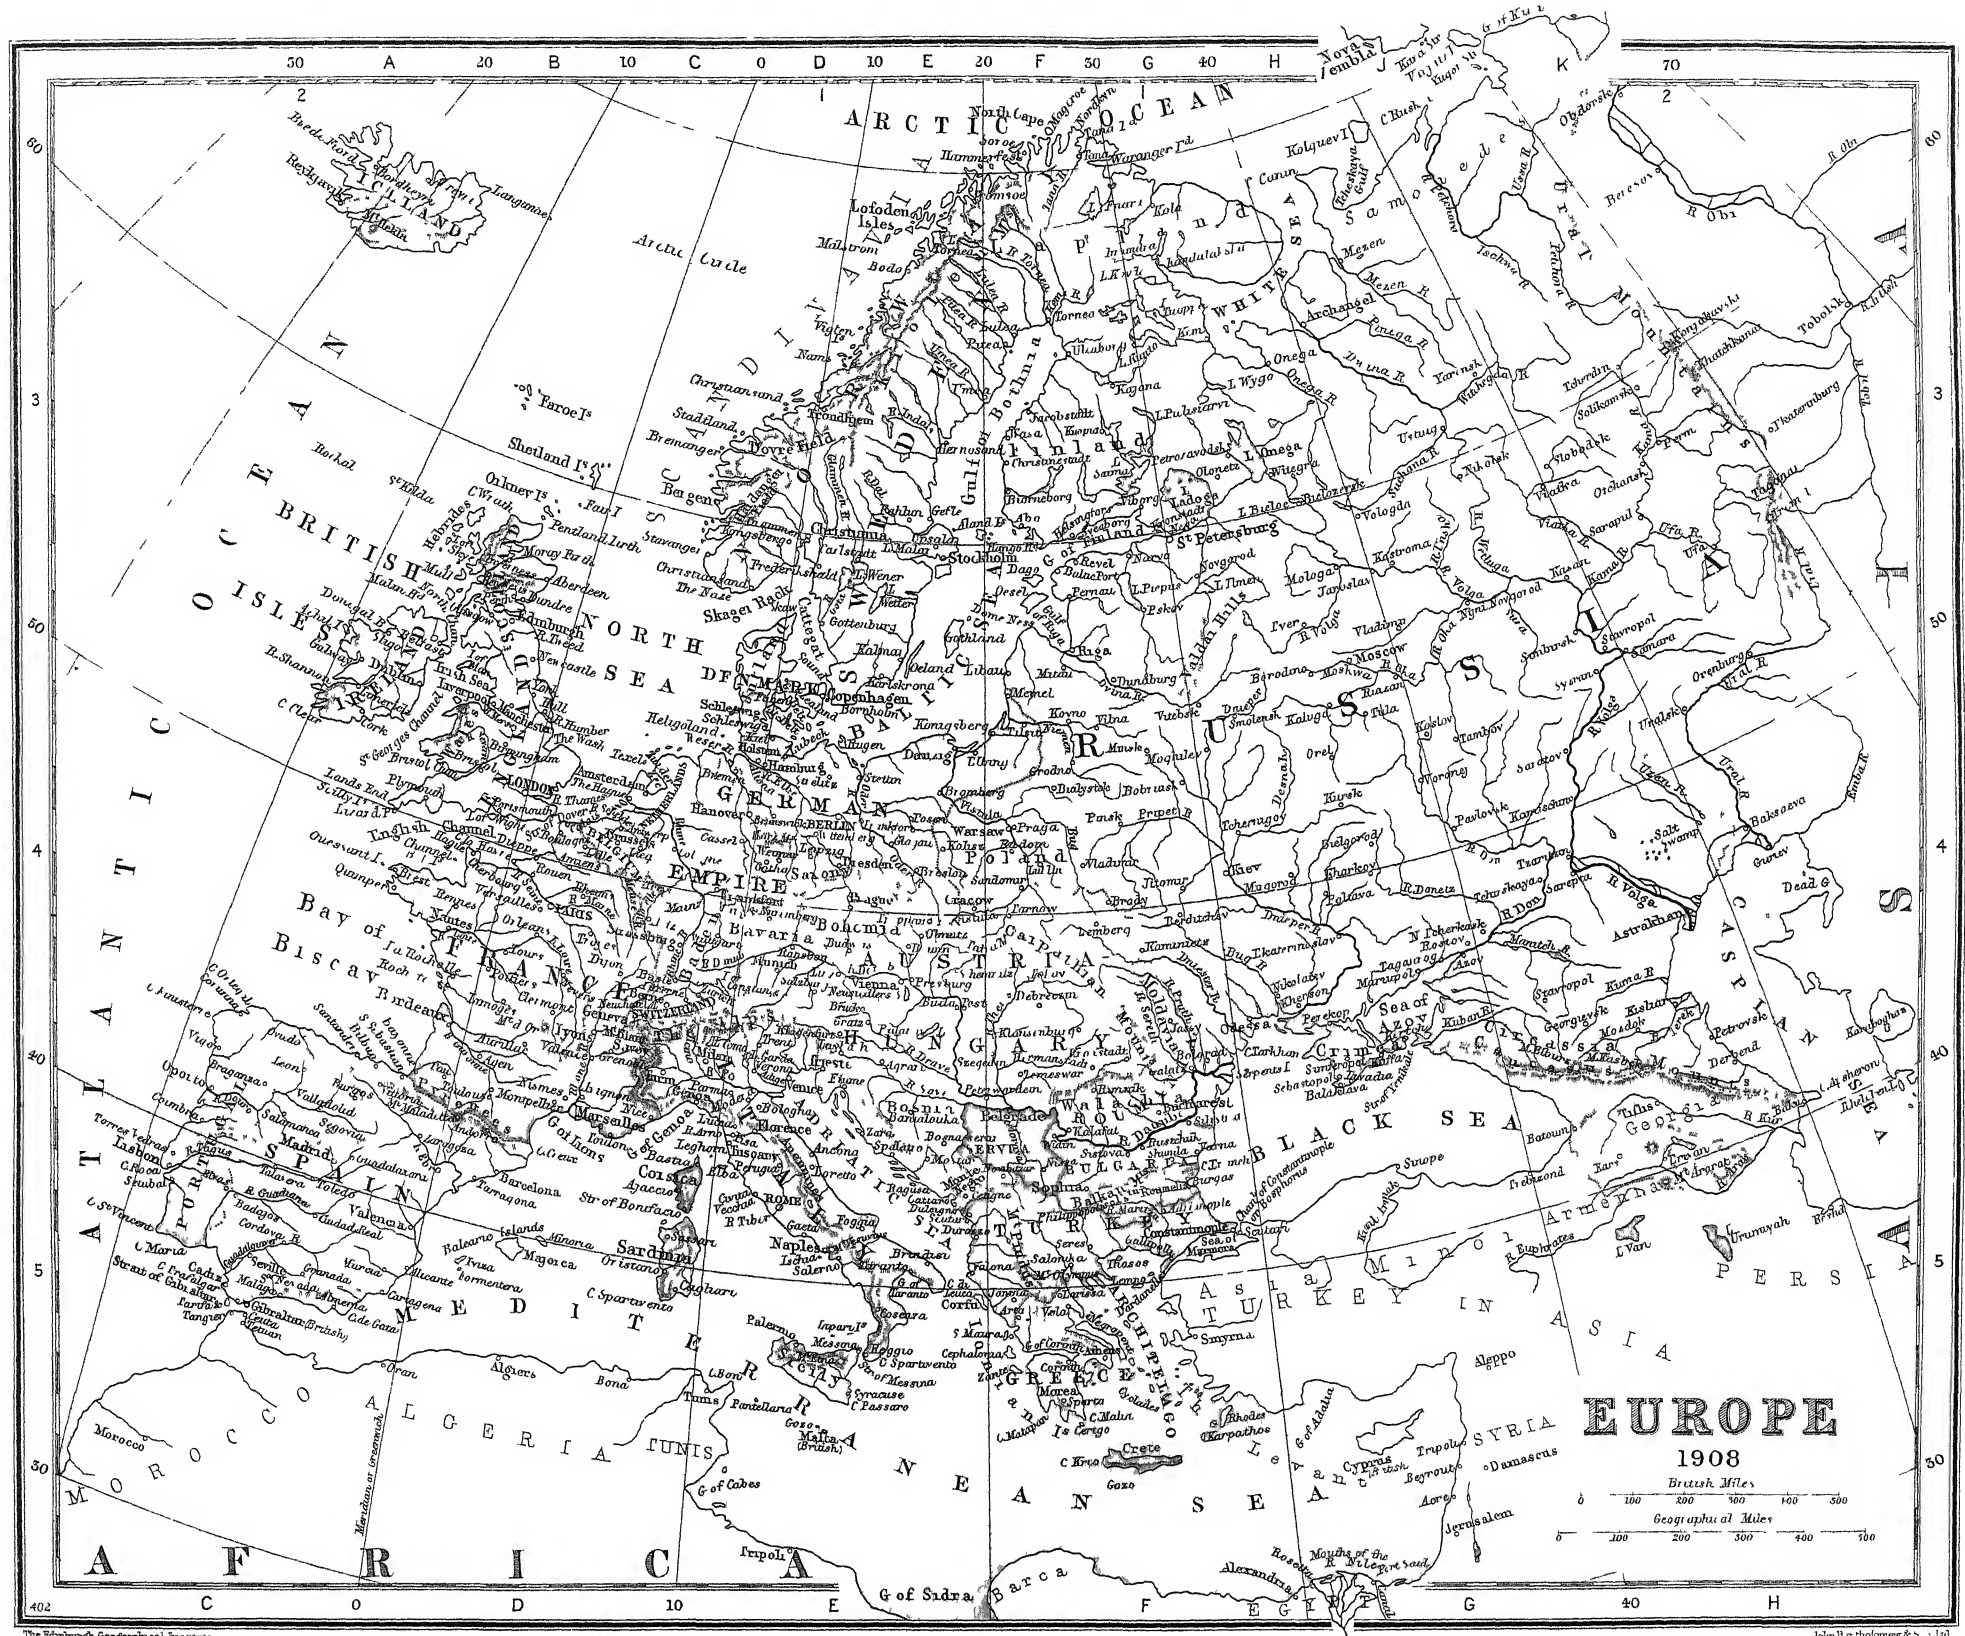

Eurydice. See ORPHEUS.

Eurypharynx. See PELICAN FISH.

Eurypterida (Gr. *euryis*, 'broad'; *pteron*, 'a wing'), an extinct order of Arthropods, belonging to the class Arachnida. The name was given because of the broad, wing-like character of the sixth (last) pair of head appendages. The Eurypterida were aquatic animals, breathing by gills like the Xiphosura, and these two orders are sometimes grouped in a sub-class, *Meiostomata*, in distinction to the true Arachnida, such as the scorpions, which are terrestrial and breathe by lungs or tracheæ. In their general appearance the eurypterids resemble living scorpions. The number of segments and their arrangement into three regions of prosoma, mesosoma, and metasoma are the same. The character of the two pairs of eyes is similar. In both the prosoma carries six pairs of appendages, similar in position and general form. The leaf-like gills of the eurypterids represent the lung-books of the scorpions. In both groups the metasoma is without appendages, and ends in a telson or tail-spine. The body of the eurypterids was protected by a chitinous skeleton.

The eurypterids are confined to rocks of Palæozoic age, ranging from the Cambrian to the Permian. The only known Cambrian form is *Strabops*, which occurs in Missouri. The order reached its maximum development in Upper Silurian and Lower Old Red Sandstone times. Specimens of *Eurypterus* have been found in a remarkable state of preservation in the Silurian of the Isle of Oesel in Esthonia. The chitinous skeleton has undergone so little carbonisation that the carapaces can be detached from the surrounding marl and examined by transmitted light. Some of the finest specimens of eurypterids have been obtained from the Upper Silurian rocks of the Pentland Hills and Lanarkshire, the commonest genera being *Eurypterus*, *Pterygotus*, *Slimonion*, and *Stylonurus*. Associated with these is a primitive type of scorpion (*Palæophonon*) intermediate in character between living scorpions and the extinct eurypterids. *Pterygotus anglicus*, which occurs in the Old Red Sandstone of Scotland, attained a length of nearly six feet, and may be noted as the largest known Arthropod. *Eurypterus* also occurs in the Old Red Sandstone; it is the chief genus in the Carboniferous, and one species at least lingered into Permian times.

The earliest eurypterids were marine—they are always found associated with characteristic marine organisms; later, they adapted themselves to live

in brackish or even in fresh water conditions. Research has shown that the Eurypterida, the Xiphosura (the only living representative of which is *Limulus*, the king-crab), and the Scorpionida are intimately related. Of these orders the Eurypterida is the most primitive, but all have probably descended from a common ancestor.

Eurystheus. See HERCULES.

Eusden, LAWRENCE. See LAUREATE.

Eusebius of Cæsarea, the father of ecclesiastical history, was born probably in Palestine about 264 A.D. He took the surname of Pamphili from his friend Pamphilus, Bishop of Cæsarea, whom he faithfully attended for the two years (307-309) in which he suffered imprisonment during the persecution of Diocletian. He then went to Tyre, and afterwards to Egypt, where he was himself thrown into prison on account of his religion. He became Bishop of Cæsarea about 313, took a prominent part in the Council of Nice, and died in 340. Eusebius was the head of the semi-Arian or moderate party in the Council of Nice. That party was averse to discussing the nature of the Trinity, and would have preferred the language of Scripture to that of theology in speaking about the Godhead. Eusebius held that the promise of everlasting life was to him that *believeth on the only-begotten Son*, not to him that *knows how He is begotten of the Father*. He was very reluctant to accept the term *homoeousios*, devised by Athanasius to describe the equality of the Son with the Father, and retained the kindest feelings towards Arius after the views of the latter were condemned (see ARIUS). His moderation and other excellent qualities procured him the favour of Constantine, who declared that he was fit to be the bishop of almost the whole world. Eusebius has the reputation of being the most learned Father of the Church, after Origen and Jerome. His *Chronicon*, a history of the world down to 328 A.D., preserved in Latin by Jerome (ed. Fotheingham, 1905, 1923), in Armenian, and in a Syriac epitome, is valuable as containing extracts from many ancient writers whose works are no longer extant. His *Preparatio Evangelica*, a collection of such statements in old heathen authors as were fitted to make the mind regard the evidences of Christianity in a favourable light, also contains specimens of writings that no longer exist; its complement is the *Demonstratio Evangelica*, in twenty books, ten of which are extant, intended to convince the Jews of the truth of Christianity from the evidence of their own Scriptures. His most important work, however, is the *Ecclesiastical History*, in ten books. This relates the principal occurrences which took place in the Christian church till the year 324, and contains the results of his studies in numerous libraries, and even in the imperial archives, the Emperor Constantine having ordered, at Eusebius' request, an examination of all documents relative to the history of martyrs. One drawback of the work is that Eusebius, on principle, withholds all account of the wickedness and dissensions of Christians, inasmuch as he did not consider such stories for the edification of the church (see CHURCH HISTORY). Besides the foregoing works may be mentioned his *De Martyribus Palestine*, the treatises against Hierocles and Marcellus, the *Theophania* (discovered in 1839), and a panegyric Life of Constantine. An edition of all Eusebius' works (in Greek) was begun in 1902 by the Berlin Academy.

Eusebius of Emesa was born at Edessa, and studied under Eusebius of Cæsarea, and at Alexandria and Antioch. Averse to all theological controversies, he declined the bishopric of Alexandria, vacant by the deposition of Athanasius. He was afterwards, however, appointed Bishop of Emesa, in

Syria, but was twice driven away by his flock, who accused him of sorcery on account of his astronomical studies. He died at Antioch about 360. The homilies extant under his name are probably spurious.

Eusebius of Nicomedia, Patriarch of Constantinople, related to the Emperor Julian by the mother's side, was appointed Bishop of Beryta (Beirut) in Syria, and afterwards of Nicomedia. He appeared as the defender of Arius at the Council of Nice, and afterwards placed himself at the head of the Arian party. He baptised the Emperor Constantine in 337, became Patriarch of Constantinople in 339, and died in 342. His enemies are our only sources of information as regards his character and opinions; yet, making the ordinary allowance for partisanship, there would seem to be sufficient reason for concluding that Eusebius was cunning and double-tongued when occasion required, and imperious and violent when he had power in his hands. Athanasius considered him not the disciple, but rather the teacher of Arius. See ARIUS.

Euskarian. See BASQUES.

Eustachio, BARTOLOMMEO, an Italian anatomist, who was physician-in-ordinary to the popes, and professor of Medicine in Rome, where he died in 1574. His name is indissolubly associated with anatomical science through his discoveries of the tube in the auditory apparatus (see EAR) and the rudimentary valve at the entrance of the inferior vena cava in the Heart (q.v.), which are called after him. These and other discoveries are recorded in his *Opuscula Anatomica* (Venice, 1564); his *Tabulæ Anatomicae* were edited by Lancisi in 1714.

Eustathius, a celebrated Greek commentator on Homer and the geographer Dionysius, was born at Constantinople. He was at first a monk, then a deacon and teacher of rhetoric in his native city; he was Archbishop of Thessalonica from 1160, and of Myra from 1174, and died at an advanced age some time posterior to 1185. Eustathius was profoundly versed in the ancient classic authors, and a man of prodigious acquirements; and the value of his quotations is heightened by the consideration that most of the works from which he extracts are no longer extant. His most important work is his commentary on Homer (1st ed. Rome, 1542-50), a rich mine of knowledge. Of a similar character is his commentary on Dionysius, first printed by Robert Stephens (Paris, 1547). Of his commentary on Pindar, only the *Proemium* has come down to us, a part of his theological and historical treatises, letters, &c. was published by Tafel in 1832.

Eutaw Springs, a small affluent of the Santee River, in South Carolina, near which the last serious battle in the American war of independence was fought, 8th September 1781. The Americans, under Greene, drove the British from their first position, and on their retreat during the night took many prisoners. The British claimed a victory because they held their position unmolested during the afternoon.

Euterpe (i.e. 'she who delights'), one of the nine Muses (q.v.). She was the muse of lyric poetry, and is represented in ancient works of art with a flute in her hand.

Euterpe, a genus of Palms (q.v.). *E. oltracea* and *E. edulis*, closely related species called Palmeto or Cabbage-palm, are cultivated in Brazil (Para, &c.), both for the cabbage (the stem then serving for palisades), and for the sake of the fruit, which yields the basis of a refreshing drink. See ASSAI.

Euthanasia (Gr.), an easy death, or a painless method of putting to death. The use of narcotics or other means for shortening life in disease has never become a subject of discussion in modern civilised countries, but it is often a very practical

question how far such means are admissible for soothing the last hours of life, when the approach of death does not itself dull the consciousness and the sensibility to pain.

Eutin, Weber's birthplace, near Lubeck.

Eutropius, a Latin historian, concerning whom we only know that he filled the office of secretary to the Emperor Constantine, fought against the Persians under Julian, and died probably about 370 A.D. His *Breviarum Historiæ Romanæ*, giving a short narrative of Roman history from the foundation of the city to the time of the Emperor Valens (364 A.D.), is written in an extremely simple style, and appears to have been originally intended for the use of schools. It became very popular as the taste for original investigation declined, and is either copied or followed by the early monkish annalists; it was twice translated into Greek, and was continued by others down to the 9th century. The History existed in three distinct forms at the revival of letters: the genuine work of Eutropius in ten books; the expanded editions of Paulus Diaconus and others; and a complete but largely interpolated copy contained in the *Historia Miscellæa*. The *editio princeps*, printed at Rome in 1471, was from the impure text of Paul.

Eutyches, an archimandrite at Constantinople, from whom the Eutychian controversy took its name. His christological views were an exaggeration of those of Cyril of Alexandria. He held that after the incarnation of Christ everything human in him had become merged in his divine essence, and that Christ therefore had but *one nature*. His personal enemies Domnus of Antioch and Eusebius of Dorylæum denounced him to Flavian, Archbishop of Constantinople, and at a synod held there in 448 A.D. he was condemned as a Valentinian and Apollinarian heretic. An œcumenical council was, through the influence at court of Dioscurus, Cyril's successor at Alexandria, called to Ephesus for a renewed investigation of the matter in dispute. Leo, Bishop of Rome, at the critical moment reversed the policy of the Roman see (his predecessor Celestine had favoured Cyril), and wrote to Flavian his famous epistle, in which he set forth authoritatively the doctrine of the two natures and one person. The council met at Ephesus in August 449, under the presidency of Dioscurus, and, under fear of the fists of his fanatical monks, decided everything exactly as he wished. Eutyches was restored, and Flavian, Eusebius of Dorylæum, Theodoret, and Domnus of Antioch were deposed. On the death of Theodosius II. the government passed into the hands of his sister Pulcheria and her husband Marcian (28th July 450). The fourth œcumenical council met at Chalcedon (q.v.), 8th October 451, and, though the greater number of the five or six hundred bishops shared the views of Dioscurus, the imperial authority insured the acceptance of the formula of Leo, and the resolutions passed in 449 by the 'Robber Council' (*latrocinium Ephesinum*)—the name given it by Leo—were annulled, as having been extorted by fear. Eutyches, who had previously been a second time excommunicated by Anatolius, Patriarch of Constantinople, was removed from the neighbourhood of the capital by Marcian before the meeting of the council. Afterwards, on the advice of Leo, he was transported to some remote place, but his subsequent history is unknown. The Eutychian sect was from 452 put down by penal laws.

For the later history of the opponents of the decrees of Chalcedon, see GREEK CHURCH.

Euxine. See BLACK SEA.

Evagrius, surnamed SCHOLASTICUS, a church historian, was born at Epiphania in Syria in 536.

An advocate by profession, he filled more than one administrative office under the Roman emperors. His *Ecclesiastical History*, covering the period from 431 to 594, forms a continuation of that of Eusebius. Although marred by the credulity of its age, it is on the whole fairly trustworthy.

Evander, son of Hermes by an Arcadian nymph, called in Roman traditions Carmenta or Tiburtis. About sixty years before the Trojan war he is said to have led a Pelasgian colony from Pallantium, in Arcadia, to Italy, and to have landed on the banks of the Tiber, and near the foot of the Palatine Hill. Here he built a town, naming it Pallantium after the one in Arcadia. At a later period it was incorporated with Rome, and is falsely affirmed to have originated the names Palatinus and Palatium. He did much to introduce the habits of social life among his neighbours; he prescribed for them milder laws, and taught them, among other arts, those of music and writing. To him is also ascribed the introduction of the worship of the Lycæan Pan, with that of Demeter, Poseidon, and other deities. Virgil represents him as being still alive when Æneas arrived in Latium after the sack of Troy, and as having sent him aid under his son Pallas, who fell by the hand of Turnus. Evander was worshipped both at Pallantium, in Arcadia, and at Rome.

Evangelical (lit., 'according to the gospel.' Gr. *euangelion*), a designation originally claimed by all Protestants, on the ground that their tenets were derived solely from the Evangel (in the widest sense)—i.e. the Bible, but in later times more particularly attached to the school that insists especially on the total depravity of unregenerate human nature, the necessity of conversion, the justification of the sinner by faith alone, the free offer of the gospel to all, and the plenary inspiration and exclusive authority of the Bible—views largely held by the Presbyterians of Scotland, the Nonconformists in England, and the corresponding churches in America and the British colonies. The adherents of this view within the Anglican communion are (with others) called the 'Low Church.' In Germany it is the special designation of the United Church, as distinguished from the old Lutheran and Reformed churches, but the title has been assumed by the pietistic party within the Protestant churches, on the ground of their superior orthodoxy and absolute faith in Scripture. See CHURCH HISTORY, and ENGLAND (CHURCH OF); also G. R. Balleine, *History of the Evangelical Party* (1908); G. W. E. Russell, *Short History of the Evangelical Movement* (1915); S. Baring-Gould, *The Evangelical Revival* (1920); and *Liberal Evangelicism*, by members of the Church of England (1923).

Evangelical Alliance, an association of evangelical Christians belonging to various churches and countries, which, in the words of the circular issued by members of different churches in Scotland, 5th August 1845, and originating the movement for its formation, seeks 'to associate and concentrate the strength of an enlightened Protestantism against the encroachments of Popery and Puseyism, and to promote the interests of a scriptural Christianity.' At a meeting held at Liverpool, October 1-3 of that year, the scope of the association was extended to the means to be used for counteracting religious indifference. In 1846 (19th August-2d September) the first general conference was held in London under the presidency of Sir Culling Eardley, and was attended by 921 members from all parts of the world, representing as many as fifty different denominations. The association was instituted a free union, not of churches or sects, but of individual Christians,

and the membership was confined to those holding 'the views commonly called evangelical' on the following nine points of doctrine: (1) The divine inspiration, authority, and sufficiency of Holy Scripture; (2) the right and duty of individual believers to exercise their judgment in the interpretation of Scripture; (3) one God and three Persons in the same; (4) human nature utterly corrupted by the fall; (5) the Son of God made man, His work of reconciliation for men's sins, and His mediatorial intercession and reign; (6) the justification of the sinner by faith alone; (7) the work of the Holy Spirit in the sinner's conversion and sanctification; (8) the immortality of the soul, the resurrection of the body, the judgment of the human race by Jesus Christ, together with the eternal felicity of the righteous and punishment of the wicked; (9) the divine institution of the Christian ministry, and the obligatory and perpetual ordinance of baptism and the Lord's Supper.

Evangelical Association, a sect closely akin to the Methodists both in government and doctrine, founded by Jacob Albrecht or Albright, who was born in the State of Pennsylvania, 1st May 1759. Originally a Lutheran, he travelled through several States as an evangelist, and in 1800 organised his adherents in 'classes' after the Methodist manner. In 1807 he was appointed bishop, and down to his death, 18th May 1808, he was the leader of the sect, which in 1818 assumed the name Evangelical Association of North America. Since 1843 it has drawn many adherents from the English-speaking population.

Evangelical Union, the name assumed by a religious body constituted in Scotland in 1843 by the Rev. James Morison (1816-93) of Kilmarnock (afterwards of Glasgow), and other three ministers, along with the congregations adhering to them. They had been separated from the United Secession Church on account of their doctrinal views, and were soon increased by a number of ministers and churches expelled from the Congregational Union of Scotland for holding similar doctrines. Their ecclesiastical system was a modified independency. Their doctrine is expressed in a *Doctrinal Declaration*, issued in 1858 as an explanation, not a fixed creed. In 1896 they were incorporated with the Congregational Union of Scotland (see INDEPENDENTS).

Evangelist (Gr., 'a bringer of good tidings') denotes in the New Testament a preacher of the gospel. In Ephesians, iv. 11, 'evangelists' are distinguished on the one hand from the apostles and prophets, and on the other from the pastors and teachers, and hold a rank between both. They were not, like the latter, attached to individual congregations, but preached as *missionaries*, without having the authority of the apostles chosen as witnesses from the beginning by Jesus himself, or of the prophets, who testified from special inspiration. Philip and Timothy were such evangelists.—The term evangelist is also applied to the authors of the gospels (Gr. *evangelion*).

Evans, SIR GEORGE DE LACY (1787-1870), general, was born in Ireland, and served in India and the Peninsula, in the American campaign of 1814, and at Waterloo. An advanced Liberal, he sat in parliament in 1831-41 and 1846-65. During 1835-37 he commanded the 'Spanish Legion,' 10,000 strong, for the young Queen Isabella against the Carlists. In command of a division in the Crimea, he was wounded in the battle of the Alma, and repelled a Russian attack before Sebastopol. In 1855 he received the thanks of the House of Commons, and was created G.C.B. He died 9th January 1870.

Evans, SIR JOHN, K.C.B., F.R.S., and D.C.L. (1823-1908), was born at Market Bosworth, and after a successful career as a paper-manufacturer, became

eminent as numismatist and antiquary. He was president of the British Association, of the Society of Antiquaries, and of the Geological, Numismatic, and other learned societies, and wrote standard books on the coins (1864) and of the stone (1872) and bronze (1881) implements of ancient Britain.—His son, Sir ARTHUR JOHN EVANS, was born at Nash Mills, Herts, in 1851, was educated at Harrow, Brasenose, and Gottingen, travelled in the Balkans, and in 1884-1908 was keeper of the Ashmolean Museum at Oxford. In 1909 he became professor of prehistoric archaeology. He has been since 1893 singularly successful in his excavations in Crete (q.v.), where he disclosed a great civilisation hitherto unknown, whose importance, from the point of view of world-history, can hardly be over-estimated. He has written on Bosnia, Illyria, Mycenæ, and Crete.

Evans, MARIAN. See ELIOT, GEORGE.

Evans, OLIVER, an American inventor, born in Newport, Delaware, in 1755, made several notable improvements in flouring-mills, and is said to have invented the first steam-engine constructed on the high-pressure principle, the drawings and specifications of which he had sent to England in 1787 and 1795. In 1804 he completed a steam-dredging machine, which propelled itself on wheels to the river Schuylkill, a distance of a mile and a half, and thus is considered the first land-carriage worked by steam in America. Evans also projected a railway between New York and Philadelphia, which his narrow means never allowed him to realise. He died in New York, 21st April 1819.

Evanston, a city of Illinois, on Lake Michigan, 12 miles N. of Chicago, with a number of handsome residences, the Garrett Biblical Institute, the North-western University (Methodist), and various colleges; pop. 37,000.

Evansville, a port of entry and capital of Vanderburg county, Indiana, on the Ohio, 162 miles ESE. of St Louis by rail, with a city hall, a court-house, a handsome post-office and custom-house, and a public library and art gallery. Coal and iron ore abound near by, and the town has a large number of factories of various kinds, besides a very considerable trade in tobacco, flour, &c. Pop. (1870) 21,830; (1900) 59,007; (1920) 85,264.

Evaporation, or VAPORISATION, is the process by which a substance changes into the state of vapour. Some solids visibly evaporate—e.g. solid ice or snow gradually disappears though the temperature may be considerably below the freezing-point. The characteristic smell of certain metals, such as copper or iron, is supposed to be due to slow evaporation (see SUBLIMATION). The change of a liquid into the state of vapour may go on at all temperatures; but the rate of change is greater the higher the temperature is, until at last boiling—i.e. free evaporation—occurs (see BOILING). Slow vaporisation at temperatures below the ordinary boiling-point is used on a large scale for commercial purposes, when it is wished to crystallise out a substance which is held in solution. The rate of evaporation depends upon the amount of surface exposed. It depends, too, upon the pressure under which the vapour is developed, and thus evaporation goes on quickly if the vapour is removed as rapidly as it is formed, as is the case when wind blows over the surface of water or snow. The temperature at which boiling occurs also depends upon the pressure. This may readily be shown by boiling water in a glass flask until the steam has driven out most of the air. If the flask be now corked, and the source of heat be withdrawn, the boiling will cease. But if cold water be poured on the flask the boiling will recommence at once. This is due to the fact that the lowering of tempera-

ture causes condensation of some of the steam, and this lowers the vapour-pressure so far as to allow of free evaporation at the reduced temperature. At any given temperature evaporation ceases when a certain pressure of the vapour is arrived at, or, more correctly, a state of equilibrium is reached in which condensation balances evaporation. Condensation occurs at all pressures; but, if the proper pressure corresponding to the temperature is not reached, evaporation exceeds condensation; while, if the vapour-pressure is too great, condensation exceeds evaporation. The presence of another gas or vapour, such as ordinary air, has no effect upon the final value of the pressure which is attained; but the time taken to reach this final pressure does depend very greatly upon the presence of another gas. The time becomes greater as the amount of gas present increases. This state of equilibrium is disturbed at once by any variation of vapour-pressure or of temperature. A vapour is said to be *saturated* when it is in equilibrium in contact with its liquid.

A considerable amount of heat is absorbed in the process of evaporation. The amount depends upon the nature of the liquid, and also upon the temperature of evaporation. Regnault gives for 'total heat' of steam the formula $606.5 + 0.305t$, in which t represents the temperature in degrees Centigrade. This means that a pound of saturated water-vapour at 0°C . gives out 606.5 units of heat when it condenses to water at 0°C ., while a pound at 100°C . would give out $606.5 + 30.5$ —i.e. 637 units in changing to water at 0°C . The heat given out by a pound of saturated steam at any temperature when it condenses to water at the same temperature is called the *latent heat* of the steam at that temperature. The term is not a good one. It has reference to the fact that the heat which is required to evaporate a substance without change of temperature disappears so far as ordinary thermometric methods of determining its presence are concerned. If we take into account the variation of the specific heat of steam with temperature, Regnault's measurements of the total heat show that at 0°C . the latent heat is 605.5 units, at 100°C . it is 536.5 units, and at 200°C . it is 464.3 units. It thus decreases very rapidly with rise of temperature. It vanishes at the Critical Temperature (q.v.). The following is the latent heat of vaporisation of a few liquids at a pressure of one atmosphere: water, 536.0; alcohol, 202.4; ether, 90.5; bromine, 45.6. It is evident from these figures that the latent heat of vaporisation of water is relatively large. Were it not for this fact we might have rapid condensation of moisture in the atmosphere in consequence of a very small fall of temperature, and in this way destructive floods might be caused.

Practical use is frequently made of the latent heat of evaporation. Thus, in order to keep water cool it should be stored in vessels of porous earthenware. Some of the water passes through the pores, and evaporates at the outer surface. The latent heat necessary for this is drawn largely from the rest of the water, which is thus kept cool. It is even possible, as was first done by Sir John Leslie, to freeze water by this process. He put some water contained in a shallow earthenware vessel inside the receiver of an air-pump along with a dish of strong sulphuric acid. When the air was exhausted, rapid evaporation resulted; but the vapour was absorbed by the acid as quickly as it was formed, and thus the evaporation was kept up continuously, so that the remaining water was rapidly cooled down to the freezing-point.

The same principle is used in the formation of solid carbonic acid and the like. A jet of liquid is allowed to escape from a strong vessel containing

it. The outer parts of the jet evaporate, and in consequence the inner parts are solidified. Faraday froze mercury in a white-hot vessel by placing it in a little capsule which rested upon a mixture of solid carbonic acid and ether in the spheroidal state.

Evarts, WILLIAM MAXWELL, American lawyer and statesman, was born in Boston, 6th February 1818, graduated at Yale, and was admitted in 1841 to the New York bar, where he afterwards built up a notable practice, receiving in some cases \$25,000 or \$50,000 for an opinion. He was chief counsel for President Johnson in the impeachment trial in 1868, and filled the office of United States attorney-general to the end of Johnson's administration. He was United States counsel before the Alabama tribunal in 1872, and senior counsel for Henry Ward Beecher in 1875. In 1877-81 he was secretary of state, and in 1885-91 sat in the United States senate. He died 28th February 1901.

Eve. See ADAM AND EVE.

Evection, a lunar inequality resulting from the combined effect of the irregularity of the motion of the perigee, and alternate increase and decrease of the eccentricity of the moon's orbit. See MOON.

Evelyn, JOHN, was born of wealthy parentage at Wotton, near Dorking, in Surrey, 31st October 1620. He was brought up by his maternal grandmother at Lewes (1625-37), then entered Balliol College, Oxford, having already been admitted at the Middle Temple, where, without a degree, he took up residence in 1640—the year of his father's death. Having witnessed Strafford's trial and execution, he resolved to absent himself 'from this ill face of things at home,' and so travelled for three months in Holland and Flanders. Back in London, 'studying a little, but daunting and fooling more,' in November 1642 he joined the king's army, only to leave it in three days' time, lest both himself and his brothers should be 'exposed to ruine, without any advantage to his majestie;' and the Covenant being pressed on him, he travelled for four years in France, Italy, and Switzerland. At Paris in 1647 he married the ambassador's daughter, Mary Browne (1635-1709); and, returning for good to England in 1652, settled at Sayes Court, Deptford, the home he did so much to beautify. A thorough, if prudent royalist, he was much at court after the Restoration; acted on several public committees; during 1685-87 was one of the commissioners of the privy seal, during 1695-1703 treasurer of Greenwich Hospital; and from the first was a prominent member of the Royal Society. In 1694 he removed to his brother's at Wotton, and let Sayes Court to Admiral Benbow, who sublet it to Peter the Great (a 'right nasty' inmate). In 1699 he succeeded his brother; and, vigorous in intellect to the very last, he died at Wotton, 27th February 1706.

'Almost perfect' is Mr Wheatley's estimate of Evelyn, who was indeed a right worthy gentleman, as active and intelligent as he was honest and God-fearing, yet neither a Sage nor a Hero. His pen was a busy one, and dealt with a multitude of subjects—architecture, painting, engraving, numismatics, history, politics, morals, education, agriculture, gardening, and commerce.' Of all his thirty-five works the chief are *Sculptura, or the History and Art of Chalcography and Engraving on Copper* (1682); *Sylva, or a Discourse of Forest-trees* (1664); and his delightful *Diary* (first published in 1818). It is to the last that Evelyn owes his present celebrity. Written by one who had accustomed himself to habits of close observation, it covers a period of more than seventy years—and these the most memorable in English history. It is, indeed, of inestimable value; Scott said that he had 'never seen a mine so rich.' See the Life by

Henry B. Wheatley, prefixed to the sixth edition of the *Duuy* (4 vols. 1879; reprinted 1906).

Evening Primrose. See *GENOTHERA*.

Everest, MOUNT, a peak of the Himalayas on the Tibet-Nepal border, the highest ascertained point on the surface of the globe, rises to a height of 29,141 feet above the sea, in 27° 59' 12" N. lat., and 86° 58' 6" E. long. It was named in honour of Sir George Everest (1790-1866), surveyor-general of India, who completed in 1841 the great trigonometrical survey, and, having retired in 1843, published in 1847 his principal work, *An Account of the Measurement of Two Sections of the Meridional Arc of India*. Everest was elected a Fellow of the Royal and other scientific societies, and was knighted in 1861. The Royal Geographical Society and the Alpine Club sent a reconnaissance party in 1921; and in 1922 a climbing party attacked the mountain from the East Rongbuk glacier on the Tibetan side. Messrs Mallory, Somervell, and Norton reached 26,800 feet without artificial supply of oxygen (some 2200 feet higher than the Duke of the Abruzzi's 'record' on K2); and Messrs Finch and Bruce with a Gurkha later reached 27,200 feet with oxygen. In 1924 Somervell and Norton reached 28,128 feet without oxygen; Mallory and Irvine (with oxygen) were lost, and were last seen at 28,226 feet. See books by Buoy and others (1922), and Bruce and others (1923).

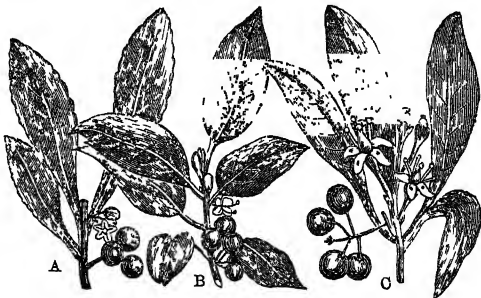

Everett, (1) a city of Massachusetts, a residential suburb of Boston, with some manufactures; pop. 40,000. (2) A city and port of Washington, with great lumber and other industries; pop. 28,000.

Everett, ALEXANDER HILL (1792-1847), diplomatist and author, born at Boston, Massachusetts, was minister at The Hague in 1818, at Madrid in 1825. Four years afterwards he returned to the United States, where he became proprietor and editor of the *North American Review* (1830-35), and also occupied a seat in the legislature of Massachusetts. In 1840 he was confidential agent of the United States government in Cuba. Commissioner to China in 1845, he died in Macao. Besides poems and several political works, he published two series of *Critical and Miscellaneous Essays* (Boston, 1845-47).—His younger brother, EDWARD EVERETT, was born at Dochester, Massachusetts, 11th April 1794, and graduated at Harvard in 1811. At the age of nineteen he had already gained a high reputation as a Unitarian preacher in Boston. In 1815 he was elected professor of Greek in Harvard College; and to qualify himself more thoroughly for his work he spent four years in Europe. Victor Cousin pronounced him 'one of the best Grecians he ever knew.' In 1820 Everett became editor of the *North American Review*, and in 1824 a member of the United States congress, sitting in the House of Representatives for ten years. In 1835-38 he was four times elected governor of Massachusetts; and in 1841-45 he was minister plenipotentiary at the court of St James. On his return to America he was elected president of Harvard College; on the death of Daniel Webster (of whom he wrote a memoir) he became secretary of state; and in 1853 a senator. In 1860 he was nominated by the Constitutional Union party for the vice-presidency of the United States, receiving 39 electoral votes out of 303. He died 15th January 1865. Everett's principal works are *A Defence of Christianity* (1814); several fine poems; and his eloquent *Orations and Speeches* (4 vols. 1836-59), covering a wide range of subjects, and indicating a varied, vigorous, and flexible genius. See Life by P. R. Frothingham (1925).

Everglades, a large shallow lake in southern Florida, enclosing thousands of islets, covered with dense thickets, and containing great numbers of alligators. Its area is diminishing. From this

district Florida (q.v.) is sometimes called the Everglade State.

Evergreens are those trees and shrubs of which the leaves do not fall off in autumn, but retain their freshness and verdure throughout the winter, and which may perform their functions during more than one year. Evergreen leaves are generally of thicker and firmer texture than the

A, *Ardisia*; B, *Holly (Ilex)*; C, *Skimmia*.

leaves of deciduous trees and shrubs. The habit most common among the larger-leaved forms is indicated in the figure—these three distinct and unrelated evergreens, *Ardisia* (*Primulaceae*), *Holly* (*Aquifoliaceae*), and *Skimmia* (*Rutaceae*), having not only the same type of leaf, but very similar small white flowers with red berries. Evergreen leaves are sometimes very small, as in firs and heaths; sometimes pretty large, as in rhododendrons, laurels, magnolias, &c. See *ECOLOGY*.

Everlasting Flower, the popular name of certain plants, the flowers of which suffer little change of appearance in drying, and may be kept for years without much diminution of beauty. They are plants chiefly of the order *Compositae*, having their flowers (heads of flowers) surrounded with an involucre, the scales of which resemble the petals of a corolla, but are rigid, membranous, and contain little moisture. Some species of Cudweed (q.v.) (*Gnaphalium*) are often called everlasting flowers, and the other plants which bear the name belong to nearly allied genera, but particularly to *Helichrysum*, *Rhodanthe*, and *Acroclinium*, which are mostly annuals and natives of Africa and Australia. *Helichrysum arenarium* is frequent on dry, sandy soils in many parts of Europe and the central latitudes of Asia. It is covered with a gray felted down, and has yellow flowers, which, when rubbed, emit a faint aromatic odour. It is often worn on the continent of Europe as an ornament in the hat, particularly by wagoners. *H. angustifolium* and *H. Stachas*—shrubby species, natives of the south of

Everlasting Flower (*Helichrysum bracteatum*).

Europe—have larger yellow flowers. Some of the species have a powerful and pleasant aromatic odour. Several kinds of everlasting flowers are frequently to be seen in our gardens; others, such as *Phenocoma* and *Aphlexis*, natives of the Cape of Good Hope, are of shrubby habit, and choice and beautiful greenhouse plants. As an instance of everlasting flowers in other orders than *Compositae*

may be mentioned the genus *Statice*; the coloured calyx in nearly all the numerous species of which it is composed is dry, membranous, and very persistent. The French call everlasting *Immortelles*, and often weave them into circular wreaths, which are placed beside recent graves, as emblems of immortality or of loving memory. A very extensive trade is now carried on by France, Germany, and Italy in growing and preserving everlasting flowers for exporting to Britain and America.

Eversley, a village of NE. Hampshire, 13 miles NE. of Basingstoke. Charles Kingsley was curate of the parish from 1842, and rector from 1844 till his death there on 23d January 1875, and he lies buried in the churchyard.

Evesham, a municipal borough of Worcestershire, on the right bank of the navigable Avon, 15 miles SE. of Worcester. It lies in a beautiful and fertile vale, and the chief industry is market-gardening. There are a fine modern bridge, public gardens, water-works (1884), a 16th-century guild-hall, &c.; but the stately Benedictine abbey (709) is represented chiefly by a beautiful Perpendicular belfry (1533). Till 1867 Evesham returned two members to parliament, till 1885 one. Simon de Montfort was defeated here, 4th August 1265. Pop. (1851) 4605; (1891) 6836; (1921) 8685. See May's *History of Evesham* (1845).

Eviction, in Law, means the dispossession of one person by another having a better title of property in land. In Scotland, the term is applied also to dispossession of movables, although in England and the United States it is restricted to lands and tenements. As popularly employed, eviction generally means the forcible expulsion of a tenant from lands and houses. The technical legal terms for this process are Ejectment (q.v.) in England, and Removing (q.v.) in Scotland. The law of Ireland as regards evictions is in a different position from that of Great Britain, from the favour shown to tenants by the Irish Land Acts. A tenant's interest in the land can be attached by creditors other than his landlord, and the tenant be evicted for failure to pay his debts, or by foreclosure of mortgage; but the great majority of cases are cases of eviction by the landlord. This eviction proceeds upon the tenant's failure to perform some part of his contract of lease—in general, the agreement to pay rent at stated periods, or the obligation to remove voluntarily when the lease has expired. Under the statutes in question, no tenant in Ireland can be evicted for non-payment of rent unless he owes at least a year's rent. Where proceedings are taken with a view to have a tenant evicted from a holding for which a judicial rent has not been fixed, the tenant may apply to the court to fix a fair rent. If a tenant has been decided by the court to be entitled to compensation for improvements, he cannot be compelled by process of law to quit his holding until the amount due to him as compensation has been made good. After a landlord has obtained his judgment, six weeks must pass before he proceeds any further, in which time the tenant may pay the amount due, and thus stay the eviction. Before the passing of the Land Act of 1887, the eviction then took place if the tenant had failed to settle; and the evicted tenant had a right to redeem for six months, and during this time the landlord was liable to him for the crops on the land. It became a widely prevailing custom for landlords, in these circumstances, to reinstate the tenant immediately after his eviction, as caretaker of the holding. After the period of redemption had run out, this caretaker might again refuse possession of the land, and be again physically removed. If he paid the amount due to the landlord, he became tenant again. The Land Act of 1887 made

law such of the rules of this custom as were in favour of the tenant. With reference to holdings of not more than £100 a year of rental (and the greater number of Irish holdings are such), it enacted that, when a landlord had obtained judgment entitling him to evict for non-payment of rent, he should (instead of proceeding to evict the tenant as formerly) serve upon him an eviction notice. The notice informs the tenant that a decree for the recovery of the land for non-payment of rent has been obtained by the landlord; that any person entitled by law to redeem the said land must do so within six months from the service or posting of the notice, by paying to the landlord, or his agent, the sum specified in the notice as rent arrears and costs; and that on service or posting of the notice the person in possession of the land, to whom the notice is addressed, is deemed to be in possession as caretaker only, and not as tenant. A return of such notices filed in court is presented from time to time to parliament, and their number is often mistaken for the number of actual physical ejections from lands which take place in Ireland. But the tenant may redeem his right within six months, and meantime remains in possession of the land as caretaker. He cannot be removed as caretaker until a month after service of the notice, unless by special leave of the court. When a warrant has been applied for for his removal as caretaker, the justices may put a stay upon the issue of the warrant for a month or less, if they think that, by reason of the illness of the caretaker, or any other cause, the proceedings ought to be delayed.

Evidence. Evidence may be defined as the means of proving an unknown or disputed fact. In ordinary legal usage the term has two meanings which should be distinguished. In one it denotes testimony as to the existence of facts; in the other it denotes relevancy to an issue, as when it is said that 'hearsay is not evidence.' Evidence is divided into (1) oral or parole evidence, statements made by word of mouth by witnesses in court; (2) documentary evidence, the testimony derived from writing, or the use of any conventional symbols which, like letters, serve to express ideas; (3) real evidence, the testimony of things, as where footprints in a field give evidence that some one has been there. Another distinction is drawn between direct and circumstantial evidence. Direct evidence is the testimony of witnesses to what they have themselves observed or know of their own knowledge regarding the fact to be ascertained, as when A testifies that he saw B stab C with a knife. Circumstantial evidence is testimony given by witnesses to what they have observed or know regarding facts more or less remotely connected with the unknown or disputed fact, as when A testifies that he found upon B a blood-stained knife. The relative value of direct and circumstantial evidence as proof of fact has been much discussed. Direct testimony is generally esteemed the stronger; but witnesses may be mistaken, deceived, or deliberately false; while circumstances 'cannot lie,' and the conclusion forced upon the mind by an unbroken train of circumstances pointing in the same direction is often more forcible than positive direct testimony.

Instances may be found in which combinations of facts and circumstances are morally satisfactory as grounds of assurance and judgment, and, in many cases where a conviction has proceeded upon circumstantial evidence alone, the prisoner has afterwards confessed his guilt. A good example is the case of Courvoisier, the valet and murderer of Lord William Russell (1840). Here there was no direct testimony whatever to connect the accused with the crime, and there were circumstances designed by the accused to suggest that it was the

work of burglars. It was proved, however, that the prisoner had an opportunity of committing the crime, that some of the abstracted property had been concealed in his pantry, and that he personally had disposed of other portions of it. The evidence, besides, excluded the reasonable belief that any other than the prisoner was guilty, and upon these grounds he was convicted, and afterwards confessed. On the other hand there have been cases, happily rare, in which a miscarriage of justice, and the conviction of the innocent instead of the guilty, have resulted from a reliance by the jury upon circumstantial evidence. The most remarkable of these that has occurred in recent times arose out of a burglary committed at the rectory of Edlingham in 1879. Two burglars, one of whom shot at the rector, were seen on the night by the rector and another person. Two men were arrested and tried for the crime at Northumberland Assizes in 1879. Neither the rector nor the other person who had seen the burglars was able to identify the prisoners, and the defence was that the case for the prosecution was wholly one of mistaken identity. But a chisel found in the room where the crime was committed was traced to the possession of the prisoners; a piece of newspaper picked up in the same room was found to correspond with a piece in the coat of one of the prisoners; and footmarks found near the scene of the crime corresponded with those of the prisoners. The jury on this evidence found them guilty, and they were sentenced to penal servitude for life. They served in the convict settlement at Portsmouth for nine years; when, in 1888, the true burglars, two other men than those who had been convicted, confessed to the crime. Inquiries were made by the authorities, with the result that the men who had been convicted on the evidence of the chisel, the newspaper, and the footmarks, were set at liberty.

Judges and juries are not allowed by law to proceed upon their private knowledge of facts at issue before them, and must decide according to the evidence adduced. Of some facts, however, a judge takes 'judicial notice,' and these do not require to be proved by evidence. Such are all public acts of parliament, the proceedings and privileges of parliament, the course of proceeding and all rules of practice in force in the Supreme Court of Justice, the ordinary course of nature, natural and artificial divisions of time, the meaning of English words, and many other matters which judges are by statute specially directed to notice. Judges are also bound under the rules of law called presumptions to draw a certain inference from a certain fact unless the truth of such inference is disproved. A *presumptio juris et de jure* does not allow its inference to be disputed. For example, the law presumes that a minor is incapable of managing his own affairs; and, when a man is proved to be a minor, he will be held so incapable without regard to the question whether in truth he is so or not. A *presumptio juris* may be rebutted, as thus: the law presumes that when a woman is married, her husband is the father of her children; but evidence may be adduced to prove the contrary. A third kind of presumption has been distinguished, the *presumptio iudicis vel hominis*, but this is merely another name for an argument or inference of logic. With regard to disputed facts that are not matter of judicial notice or legal presumption the general rule is that he who affirms a fact must prove it; and the burden of proof lies in the first instance on the party against whom judgment would be pronounced in the absence of evidence on either side.

The general rule governing questions as to what facts may be proved in judicial proceedings is

that facts in issue (or those upon which the existence of the legal right in question depends) and facts relevant to the issue—i.e. those from which the facts in issue may be inferred—may be proved to the exclusion of all other facts. Facts collateral to the issue are not allowed to be proved—e.g. in a question whether A committed a crime, the fact that he formerly committed another crime of the same kind is held to be irrelevant, and not allowed to be proved. Hearsay evidence—i.e. testimony to the fact that a statement was made by a person not called as a witness—is similarly deemed to be irrelevant, the reason generally assigned being that the best evidence must be given. But the rule excluding hearsay suffers exceptions. Thus, voluntary confessions of crime and declarations by persons accused of crime are admitted as evidence against themselves; and declarations made by witnesses at the point of death, or in fear of death, are received as evidence against others. The opinion of a witness, as distinguished from his testimony to a fact, is generally held to be irrelevant; but the opinion of skilled persons or experts as to matters coming within their special province is admitted. Thus, in a question whether a man was sane when he made his will, the testimony of a witness to the fact that the deceased wrote his will in different coloured inks upon medicine labels would be deemed relevant, while the same witness's opinion that 'no sane man would make a will in that way' would be deemed irrelevant; but in a question whether A was poisoned, the opinion of medical men is admitted as to the effects of the poison of which A is said to have died. Evidence as to a person's character is deemed to be relevant in an inquiry regarding his conduct.

Admissible facts may be proved by documentary or by oral evidence. When the contents of documents are proved by the production of the document itself in court, the evidence is said to be primary. When copies are produced, the evidence is said to be secondary. As a general rule the documents themselves are necessary, as being the best evidence; but copies are accepted in certain settled cases—as where the original is in possession of the adverse party, who refuses to produce it; where it has been destroyed or lost; or where it is of such a nature as not to be easily movable, as in the case of a libel written on a wall. Public documents, such as the records of the realm, the acts of parliament, and the like, are proved by copies variously authenticated. When the law requires writing as proof, or where, e.g., a contract is *de facto* written, oral evidence in contradiction will not be admitted. Such evidence will, however, be received for the interpretation and construction of documents where they are obscure or couched in language used out of its ordinary sense.

The old rules which restricted or excluded the admissibility of a witness on the ground of religion, of interest, and of character have been gradually swept away by legislation. Objections of interest and character do not now affect the admissibility of witnesses, but are urged against their credibility when their testimony has been received. As a general rule all persons who are capable of giving rational evidence are admissible as witnesses. Extreme youth and mental infirmity will exclude if it is such as to prevent the witness from understanding questions or giving rational answers, or from knowing that he ought to speak the truth. In criminal cases the accused was formerly not admissible as a witness, nor the husband or wife of the accused, except where he or she was the person injured by the crime. Some exceptions were made, e.g. by the Criminal Law Amendment Act, 1885, which allowed persons accused of offences under it

and their husbands or wives to be competent witnesses. The rule itself was abolished by the Criminal Evidence Act, 1898, by which 'every person charged with an offence, and the wife or husband, as the case may be, of the person so charged, shall be a competent witness for the defence, whether the accused is charged solely or jointly with others. Such evidence cannot be compelled, and its absence may not be made subject of comment by the prosecution. Witnesses are in the ordinary case examined in open court by word of mouth, after taking an oath to tell the truth. If any witness is unwilling to be sworn from conscientious motives, the judge may permit him to make a solemn Affirmation (q.v.). Any person who has made such declaration and wilfully and corruptly gives false evidence may be prosecuted and punished as if he had committed Perjury (q.v.). Witnesses are first examined by the party who calls them into court. After this examination-in-chief they are cross-examined on behalf of the opposite party, and then re-examined. Leading questions—i.e. questions which suggest their own answer—may be put in cross-examination, but not in the examination-in-chief. No witness is bound to answer any question if the answer would expose him to a criminal charge; but if the result of his answer would be to render him liable to a civil suit for debt or otherwise he must answer notwithstanding. Questions may be put in cross-examination to test the accuracy or credibility of the witness, and to shake his credit by injuring his character; but the judge may disallow questions which he considers to be vexatious and not relevant to the issue. Every witness may be examined as to whether he has ever made a different statement regarding the matter of his examination; and, if he denies, proof may be led to contradict him. Spouses cannot be compelled to disclose communications made to one another during the marriage. Confidential communications between parties to legal proceedings and their legal advisers are similarly protected. Medical men and clergymen, on the other hand, may probably be compelled to disclose communications made to them in professional confidence, although the point remains doubtful (see CONFIDENTIALITY). Except in cases of treason and perjury, the evidence of one witness is held sufficient by the law of England to support a conviction; but proof of circumstances to corroborate such witness is usual. The rule runs the other way in Scotland, where no libel can be proved by the unsupported testimony of a single witness; but, as one witness is held sufficient to prove each of a chain of connected facts, the practical effect of the two rules is the same in both countries. See Sir James Fitzjames Stephen's *Digest of the Law of Evidence* (6th ed. 1904), and Kirkpatrick's *Digest of the Scottish Law of Evidence* (2d ed. 1886).

In the United States, state laws prescribe the rules of evidence which govern the state courts, and, in the absence of congressional enactments, federal courts. The effect of recent acts of congress is that there is now no restriction as to the admission of testimony based upon the colour or nationality of the witness; and in general the party in interest both in civil and criminal cases may be a competent witness, subject to the general rule that a party is not compelled to criminate himself, nor shall his silence upon any question create a presumption against his innocence, and subject also to the general rule that a husband shall not be allowed to testify against his wife, nor the wife (unless the offence has been committed by the one against the other) against her husband. Where the evidence relates to the remedy, as in the proving of an instrument by subscribing witnesses,

state rules govern both in federal and state courts; hence the practice varies with the locality. Circumstantial evidence is admitted by courts with great reluctance, and in criminal cases, if not corroborated by the positive evidence of at least one witness, it must be of such a character as to be equivalent in weight of evidence to direct and positive evidence, and be entirely inconsistent with the innocence of the party accused.

A belief in God and in divine rewards and punishments, here or hereafter, for deeds done is essential to the admissibility of a witness; and this belief must have no reference to the punishment for perjury by human law; hence one having no belief in God cannot be a competent witness, and no form of oath which he declares to be binding upon his conscience cures this defect. The jury are the judges of the fact, and, as such, of the credibility of the witnesses; hence no jury in the United States is obliged to reject a statement of a witness because uncorroborated by positive testimony, either direct or circumstantial. The general rules as to relevancy; the relative value of written and oral evidence, and the control of the one by the other; and the taking of an oath or affirmation are to the same effect as those observed in England. —For the evidences of religion, see APOLOGETICS.

Evil may be generally defined as that which is opposed to the divine order of the universe. It requires only a superficial observation to perceive that there are many apparent exceptions to the pervading harmony and happiness of creation: there are convulsions in the physical world; there are suffering, decay, and death throughout the whole range of organic existence; and the appellation of Evil is commonly applied to such phenomena. In the face of the human consciousness, such phenomena appear to be infractions of the general order and good, and it pronounces them *evil*. Every form of religion testifies to the recognition of evil in the external world, and superstition in all its shapes mainly rests upon it.

But it is in the sphere of moral life alone that the conception of evil is most deep-seated—evil in human life and manners and history. There is in the moral consciousness of man a sense of violated order, of transgression of divine law, or what is called *sin*, which is *evil* in its essential form. This fact of evil is everywhere appealed to by the Christian religion; it is the aim of this religion to deliver men from its power and misery. Every ethical and judicial code is based upon its recognition, and is designed to protect human society from its injurious consequences.

The question of the *origin of evil* has been greatly discussed, and has received various answers. The simplest and most direct of these answers is that which maintains a double origin of things, or a system of *dualism*. This conception lies at the basis of many forms of religion; it may be said to be the fundamental conception of all mere nature-religions. Interpreting the obvious appearances of nature, these embody in divine personalities its contending manifestations of light and darkness, benignity and terror. The opposition of Ormuzd and Ahriman in the old Zoroastrian faith is one of the most conspicuous examples of this religious dualism. Manichæism, which spread so widely in the 4th and 5th centuries, and the Syrian gnosticism from which it sprang, though accounted amongst Christian heresies, are also historical illustrations of the same principle.

The dualistic theory of the origin of evil, however, could not maintain itself with the advance of speculation and the truer appreciation of Christian truth. It was at once a postulate of the cultivated reason and a dictate of divine revelation that the world proceeded from One absolutely

Divine Creator, holy and good, of whom, and through whom, and to whom are all things. It was necessary, therefore, to reconcile the appearance of evil with this fundamental admission.

The doctrine of the Fall, especially in the later form of development which connects it with the existence of a devil or evil spirit, tempting man in the shape of the serpent, was supposed to explain the appearance of evil in human history. Being tempted of the devil, man sinned, and so fell from his obedience to the divine law. This is the doctrine of orthodox Christian theology, and the answer which it gives to the inquiry, how sin came into the world. And many minds never think of carrying the inquiry further. It is clear, however, that this explanation of the historical origin of evil leaves the question of its real and absolute origin unsettled. The devil being assumed as the cause of man's sin, the further question arises, whence the devil? Is he an absolute personality? in which case we are landed in the old theory of dualism; or is he, according to the traditional Christian conception, a fallen angel? in which case the question just returns, whence the spring of evil in him? (See **DEVIL**.) There is no real explanation gained by this removal of the question; it is still the same difficulty—whence the origin of evil in the creation of an all-perfect Being, almighty as well as all-wise and good?

Speculation may please itself with ingenious answers to this question, but in truth it admits of no satisfactory solution. Some, for example, have argued that evil, like darkness or cold, is an indispensable element of alternation or contrast in human life. All individual reality is only the product of opposite forces working together. Character could only arise from the interaction of opposing ethical influences of good and evil. In nature we have attraction and repulsion, rest and motion, positive and negative electricity; why should it be different in the sphere of morals? Here, too, there must be polarity. Good can only exist in contradistinction to evil; the one no less than the other is necessary to constitute the drama of human life and history. Others, again, have argued that evil is the result of what is called metaphysical imperfection. God alone can be perfectly good. The creature in its very nature is limited, defective; and evil is nothing else than the evidence of this limitation in man. It is not something real or positive, but only a privation. It is in morals what cold and darkness are in physics, a pure negation. Thus have argued such profound thinkers as Augustine and Leibnitz. But it requires but little penetration to see that such arguments, however ingenious and so far well founded, do not meet the essential difficulty of the problem. If evil be, according to such views, a necessary element of human life, in the one case in order to develop its activity, in the other case as clinging to its creaturely limitations, then plainly it is not, in the orthodox sense of the word, *evil*. It is not and cannot be a contradiction of the true idea of human life, and at the same time a necessary element of it. Whatever necessarily belongs to life must help its true development, and not injure and destroy it; must be *good* in short, and not *evil*. Such theories, therefore, only solve the problem by eliminating the fact. The origin of evil must remain for ever inscrutable; nor is it wonderful that it should. It is only in its ultimate sense conceivable as a quality of moral freedom, and moral freedom in man or any created being is a profound mystery. It is something which 'we apprehend, but which we can neither comprehend nor communicate.'

The problem of the origin and existence of evil is dealt with by the most notable philosophers, as by Kant and

Hegel, but assumes special prominence in the pessimistic philosophers, Schopenhauer and Hartmann. According to Schopenhauer, not merely does pain greatly outbalance pleasure, but existence as such is necessarily evil (see **PESSIMISM**). John Stuart Mill, in his posthumous essays (1874), held that, in the presence of so much and so great evil, physical and moral, in the universe, it was impossible for him to believe in a deity at once omnipotent and all-benevolent. He felt therefore driven to regard God as a Demiourgos limited in power by the materials on which he had to work. See also **SIN**, **WILL**; Julius Muller, *The Christian Doctrine of Sin* (trans. 1868); and Rashdall, *The Theory of Good and Evil* (1907).

Evil, KING'S. See **SCROFULA**.

Evil Eye, the power of exerting an evil influence or fascination on any one by a glance from the eyes, one of the most venerable and widespread of human beliefs, sanctioned alike by the classical authors, the Fathers of the Church, the medieval physicians, savage races everywhere, and modern usage in many countries within the range of Christianity. Readers of Virgil will remember the complaint of Menalcas in the third *Eclogue* that some evil eye has bewitched his tender lambs, and every one is familiar with St Paul's bold metaphorical use of the idea to express the spiritual perversion of the Galatians (iii. 1). By the ancient Greeks it was called *Baskania*, by the Romans *Fascinum*; and to both it was an integral part of the popular belief. Amulets of very various forms—the most common those shaped like horns, like a frog, or like a hand—were worn to counteract its effect, and such devices adopted by way of safeguard as spitting on the ground or on the breast, showing something ridiculous to the fascinator, dissimulating good fortune, or doing something unpleasant by way of a counter-penance, like Polycrates of Samos throwing his ring into the sea. It was supposed that fascination was most often due to envy; hence the philosophy of overcoming it, and converting it into laughter and safety, by the exhibition of some ridiculous amulet, often of most indecent description. Such also were the *oscilla* or little masks of Bacchus hung upon fruit-trees to avert the *fascinum* and keep them fertile, and the *phallus* borne about in procession at the Dionysia. Of similar origin is the fact that stated numbers are particularly liable to the *fascinum*, and hence the deep-rooted Jewish disinclination to number flocks or the like, and the no less strong objection of Neapolitan and Scottish fishermen to state the number of their catch. In the folklore of almost every people it is considered unlucky to be praised with any particular warmth, and it is a point of prudence to use certain formulas immediately thereafter. We find this not only among the ancient Greeks, Romans, Celts, and Teutons, but among such people as the Turks, Italians, Spaniards, as well as the Chinese, Japanese, Negroes, and Red Indians. Thus, in Carniola and Corsica a mother does not care to hear her baby praised or a farmer his crops, while even in England here and there sick people still feel uneasy at being told that they are looking much better.

Nowhere at the present day has the belief in the evil eye a more real power than among the Neapolitans. The *Jettatura* is one of the common dangers incident to life, and every one wears his amulet against it. These are usually of silver, in the form of an antelope horn, a hand with the first and little finger doubled down, a key with a heart in its handle, a crescent moon with a face in it, or a sprig of rue. Other very common forms are the *cimaruta*, an emblem combined of all the foregoing, none of which are directly Christian symbols, and the *cavallo marino* ('sea-horse') and *sirena*, the last two being very common in Pompeian

paintings. The horror of this fatal gift of fascination with its blighting influence is deepened by the fact that it is exerted upon any object upon which the eye may first light, often, if not indeed usually, in opposition to the will of the person who is cursed with it. Men now possess it more commonly than women—nay, the *jettatore* is often a priest or monk, and it was long a matter of common belief that it was an unhappy attribute of Pio Nono himself. In ancient times, on the contrary, it was more common in women than men, and was possessed most often by little old women with squint or deep-set eyes, especially those who were lean and melancholy, and had double pupils. The Neapolitan *jettatore* is traditionally a morose and sallow man, eager to cast his blighting influence over men and women, but most commonly children, and usually he is a mean-looking personage, totally unlike the portentous figure idealised in the *Corricolo* of Dumas. Many of the medieval philosophers have seriously discussed the rationale of the evil eye, with its relations to the poisonous rays emitted by toads and basilisks, and the fascination of terror exerted by the serpent upon the bird through keeping its eyes fixed steadfastly upon it. Grimm notes as one of the best means of recognising a witch, that when you look into her eyes you see your image reflected upside down, and suggests that the peculiar conformation may have had something to do with her evil eye. At anyrate this baneful property is characteristic of witches everywhere, of none more than in those of Teutonic mythology.

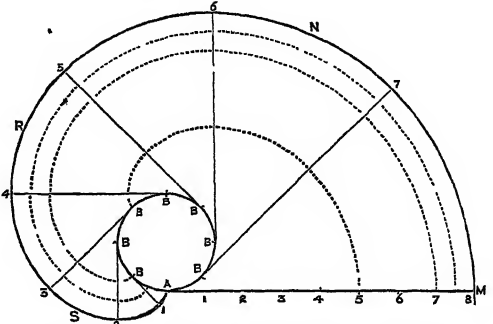

See FASCINATION; the learned discussion in W. W. Story's *Castle St Angelo and the Evil Eye* (1877); G. Pitté, *La Jettatura ed il Mal'occhio in Sicilia* (Kolozsvár, 1884); chap. vi. of E. N. Rolfe and H. Ingleby's *Naples in 1838* (1888); Tuchmann on 'Fascination' in *Mélusine* (1884-89); Elworthy, *The Evil Eye* (1895); R. C. MacLagan, *The Evil Eye in the Western Highlands* (1902); and, for Eastern evidence, papers by John de Cunha and Purushottam Balkrishna Joshi in part iii. of the *Journal of the Anthropological Society of Bombay* (1888).

Evil Merodach. See BABYLONIA.

Evolute, Involute, correlative terms first applied to the tracing of curves by Huygens. Under this distinction every mathematical curve is considered as one of a pair which are mutually produced. To measure the curvature at any point, or the amount of bending or deflection from the tangent, we find a circle which coincides with the curve for an elementary distance. This circle of curvature or 'osculating circle' must evidently diminish its radius as the curvature increases, and increase its radius as the curvature diminishes. The centre of this circle is called the centre of curvature for that point; and the successive points of any given curve have in general different centres of curvature, because the amount of deflection is constantly varying. When we trace, for example, an ellipse, the varying centre of curvature is at the same time tracing a companion curve of quite a different shape. The latter is called the evolute and the former the involute. Or we may begin with the evolute. Take a circular disc of metal or wood and wrap a thread round the circumference, which is now to serve as the generating curve. When the disc is held fast to any plane, and the string unwrapped under tension, any point of the latter will describe on the plane an involute of the circle. At any particular moment of the process the straightened or unwound part of the string is the radius of curvature of the outer curve. Thus, (1) the tangent to the evolute at any point is the normal to the involute at the corresponding point; (2) any curve as involute can have but one evolute, but any curve regarded as an evolute has an infinite number of involute

companion curves, which are all parallel; (3) the length of any arc in the evolute is the difference between the tangents at its extremities. When the circle is evolute, its involute (see fig.) is obviously spiral; and, when it is itself involute, the corresponding evolute has the exceptional form of being diminished to a point. The evolute of the cycloid is also exceptional, being another equal cycloid, a fact first observed by Huygens. A practical application of the involute of the circle occurs in theoretical mechanism in connection with the shape of the teeth of wheels, under certain circumstances.

From A, the beginning of the involute, draw a tangent AM = length of circumference of the circle.

Circle, BBB, as Evolute and its Spiral Involute, MNRSA.

Divide AM into eight equal parts (as figured) and the circumference into the same number at B, B', B'', &c. At these points draw tangents so that line B1 = line A1, B2 = A2, B3 = A3, B4 = A4, &c. The extremities of the tangents show the curve called the involute of the circle. The dotted curves show three of the companion involutes, all parallel to the first. They obviously admit of indefinite extension, however small the generating circle may be.

Evolution, in Arithmetic. See INVOLUTION.

Evolution. Upon every developing mind, whether infantile or consciously philosophic, there presses at times the question of the origin of things. The attempt to answer this is to construct a cosmogony; and is alike the earliest and the latest extension of our common-sense account of things into complete and more orderly form as science. In seeking to do this the greater and more permanent phenomena at first impress us; and our speculative restlessness, if not lulled altogether, may seek to satisfy itself by postulating the existence of the universe substantially unchanged during an infinite past. But this philosophy of things is not only incapable of being really grasped by the highest effort of the intellect, but is incessantly contradicted by experience; it has hence never gained any real acceptance from the simplest common sense, much less any confirmation from science. The alternative then arises of drawing an explanation of the origin of things from our experience not of permanence, but of change. Here it is naturally the most changeable phenomena, the most marked and sudden contrasts, which first and most deeply arouse our attention, and this not only in nature, but still more in human life and affairs. The conception of uniformity among superficially different phenomena has hardly arisen, and the demand for explanations in terms of cause and effect, other than in terms of personal volition, is proportionately weak. The hypothesis of a sudden and unexplained, of a mysterious appearance or creation of things, thus next presents

itself; and the subsequent explanation of this as an act of external will is rendered easy by our personal consciousness. As our practical and industrial powers develop, and the perception of phenomenal order deepens and extends, the original simple association of a simultaneous appearance of all phenomena with a flash of volition is modified. Phenomena are becoming classified and interconnected in larger and larger groups, with which a higher anthropomorphism can henceforth associate a conception of detailed design. The older view only remains provisionally so far as order is not yet apparent; such later creationist theories become increasingly supplemented by a recognition of the changes in progress around us. The importance of these is found steadily to increase, and the conception of evolution, nascent since the crudest view of creation had given place to a more gradual and causal explanation, now becomes independently formulated in each order of phenomena. Human affairs become more and more obviously interpretable than of old, and there arises in their place the characteristically modern idea of progress. Natural science meanwhile has become more active, the very astronomical and geological phenomena from which our ideas of permanence were most derived are seen to be in process of change. Changes which seemed to be catastrophic in their vastness are proved to be only the cumulative product of natural agencies in daily operation; and the idea of the present as the product of the past also becomes extended to the world of organic life. The details, the general mechanism and direction of the processes of change, thus become inquiries of paramount interest to each body of scientific specialists and still more to the philosopher. It is at this period that we find ourselves, and to the brief discussion of these questions therefore that we must pass; but it is useful from the outset to recognise that instead of having well-defined and sharply-opposed theories of creation and evolution, these are but phases of an incomplete evolution. Hence the controversies so active during the middle half of the last century have practically ceased; it is admitted on all hands that the evolution theory only supersedes those cruder anthropomorphisms of arbitrary creation and of mechanical contrivance which presented the universe as a mere aggregate of finished products, without excluding that higher and more unified teleology which interprets it as the orderly unfolding of a cosmic drama. And as we see the evolution theory to be an orderly development beyond its predecessors, mere destructive criticism of these becomes no longer necessary.

Mode of Treatment.—The student of theology or philosophy, or the man of general education, is usually inclined at once to plunge amid the conflicting currents, the perplexing eddies of past cosmogonic speculations. He hence sets out by reviewing the oriental theories of the universe, and comparing these with Hellenic ones; he develops mingled types of both through early Christian thought into the elaborate compromise of the scholastic world; and finally endeavours to trace the modifications and survivals of these in contact with the thought-streams of the Renaissance and the Revolution before reaching the theories of modern times. But it would be a grave mistake to suppose that these last are the product of any continuous development from the preceding course of speculation. They have arisen independently and upon a distinct line, and present themselves as the most generalised result and expression of our concrete studies of natural science. Hence such historic inquiries, in all cases difficult, if not actually misleading, would be in any case premature; whereas, when we have grappled with the

scientific theories of evolution, we may then profitably note the analogies or parallelisms, the survivals of, or reversions to, earlier modes of thought which these present.

Scientific conceptions of evolution may themselves be approached from various sides. Minds of the more abstract type or training tend to begin with such a highly generalised analysis and exposition of the subject as that with which the labours of Herbert Spencer were so pre-eminently concerned. After accepting or modifying this dynamic view of the universe as a whole, we should then seek to satisfy ourselves as to the applicability of our principles to the genesis of the physical world, and thence pass to the phenomena of life, mind, and society. We should then be accustomed to regard the universe no longer as a mere phantasmagoria, nor even merely as an orderly succession of events, but as a process of becoming. And, since this orderly flux of evolution is still in progress, scientific prevision thus becomes possible, and with it a corresponding degree of practical prevision as well. We thus reach a transition from the cosmist to the humanist attitude; the essential step from an evolutionary system of science towards an evolutionary system of ethics would then be made. These general conceptions reached, and an evolutionary philosophy in its broadest outlines being thus settled, we are in a position to review the earlier systems of different historic periods, and rationally criticise and interpret them in the light of our own conceptions; it may be even to recognise defects or deficiencies in these, and to obtain suggestions how to correct or supply them.

A less arduous and more popular method, concrete and inductive moreover, and consequently more in harmony with the modern spirit, is to begin as a scientific specialist, artificially isolating in thought one order of phenomena at a time from the complex unity of nature. Reviewing in this way the physical sciences, next the biological, and finally the mental and social, we shall be able to trace the parallel rise of evolutionary interpretations in each order of phenomena. And, after adequate detailed study of physical and organic processes, we may not only discuss the broader generalisations with fuller grasp and certitude, but proceed to inquire into the evolutionary process in higher sciences with ampler preparation; and thus ultimately approach the philosophic ideal of clearest and completest general view.

In this way we should have again completed the same cycle of thought as that sketched in the preceding section, but this time inductively instead of deductively: we have, as it were, worked our way upwards from our scientific primers instead of down from Spencer's *First Principles* or the like. In short, then, the most simple, safe, and fruitful scientific method of studying the problem of evolution we find to be to reverse the order of the three distinct methods above outlined; to commence with the concrete study of evolution as manifested in the universe as a whole, in the earth's crust, and among plants and animals; gradually to rise toward more abstract expression and more deductive grasp, then to pass to mental and social evolution. Within the present compass the utmost that can be attempted is to sketch out a few of the leading lines of thought and still more briefly indicate others.

Evolution in the Physical Sciences—Astronomy.—Here, as in other sciences, early conceptions of the universe agree in viewing it as being, as far as possible, in permanence and at rest, and not in change and motion. Such static views may be only tacitly implied, but are more usually directly avowed: thus the earth was long viewed as a

plane stably supported, and till very recently the stars were viewed as fixed. But as the static universe of the ancient astronomer passes into that of Copernicus and Kepler, Galileo and Newton, Herschel and Leverrier, dynamic, or more accurately *kinetic*, conceptions have henceforward an assured prominence in at least one science, and that the one most obviously concerned with the universe as a whole. For although evolutionary speculations of more or less vagueness seem to have arisen once and again in almost every science, the first well-developed theory of evolution which has attempted to cope with the observed facts of any science must be credited to astronomy (if not to the professed astronomer) in the famous Nebular Hypothesis (q.v.), of which the suggestiveness to all other departments of science must be freely admitted. For the mind which has once fairly grasped the conception of stellar and planetary evolution cannot readily stop there.

Evolution in Chemistry.—In chemistry kinetic conceptions must naturally have been rife from the earliest times. The records of ancient chemistry are indeed largely those of the speculative exaggerations of kinetic hypotheses by the alchemists; as its history in more modern times bears the trace of a strong, and in some respects excessive reaction from these, albeit to occupy the more certain ground afforded by the conception of the permanence of matter. But the analytic researches, the studies of atoms and elements, of valencies and molecular constitutions viewed as absolutely definite, are again being used only as starting-points for new dynamic departures, such as those of thermo-chemistry; while new speculations, essentially evolutionist, such as those of Crookes and others, have arisen on various hands around the well-known periodic law (see CHEMISTRY, PHYSICAL CHEMISTRY). The similarity in composition of our planet with that of sun and stars, and the intimate relation between organic and inorganic compounds, are also suggestive; while the actually observed genesis of many species of minerals by the action of natural causes, and the frequent transmutation of one species into another when some definite change takes place in the surrounding conditions, are not without evolutionary interest. See also RADIUM, ELECTRON.

The recent movement in chemistry above alluded to is indeed only the counterpart of what had been taking place earlier and more fully in physics, thanks largely to astronomy and to the mechanical arts, not to speak of other influences. The laws of motion, the conception of gravitation, are steps of the same progress, as are also the sublime conceptions of the conservation and dissipation of energy throughout the universe, and the revision of these conceptions required by further study of the electrical nature of Matter (q.v.). And as the analytic task of the chemist and physicist rises from that of weighing and grasping at the atom to that of watching and measuring the wave or the electron, our general conceptions are inevitably changing also. The idea of a static universe, essentially constructed once for all of so many different masses and kinds of matter, upon which man of science, philosopher, and theologian alike formerly agreed, is on all hands fully giving place to that of a dynamic unity which owes its manifold and unceasing differentiation to the varying modes or moods of the universal energy.

Evolution in Geology.—That the last-century mineralogist was here and there already widening his interest to the rocks and even meditating as to their nature and origin is well evidenced by the penetrating speculation of Linnæus: 'It may be that the solid rocks are not primeval, but the

daughters of time.' As subsequent generations of research have shown us, this solid rock is the product of igneous and that of aqueous action, here reaching back to an incalculable antiquity, or there evolved within the period of human occupancy; while others consist in great part, or even completely, of the remains of extinct animals or plants. These are conceptions now so familiar that it is difficult to realise their once revolutionary appearance and effect. But when we take into account the transition from the cataclysmal and essentially creationist theories which at first prevailed to the uniformitarian, or evolutionist, interpretation of geological phenomena which centres round the work of Lyell, we cannot wonder that such a revolution in geological doctrine should have exercised an influence upon general thought only second to that of the Copernican astronomy itself. More detailed studies, too, would be of no little service to our general theories; note, for instance, how the geologist takes from the astronomer, now a stellar evolutionist, the cooling planet, and outlines its primeval sunrises of land and sea, its wrinkling hills and vales, how he proves that the pulse of ocean is but the dying ripple of a once fiftyfold mightier tidal wave, or how the glacial period is the inexorably recurrent winter of a year of ages. The mineralogist no longer merely measures and analyses, but deciphers the origin and transmutation of mineral species, and of the rocks they form under the forces of the environment (see MINERALOGY); and the typically changeful phenomena of climate and atmosphere are rendered the subject of a typically dynamic sub-science (see METEOROLOGY).

Modal Explanation of Physical Evolution.—We must sooner or later inquire whether any general principle can be found to verify and rationalise the process of evolution in the physical world, and to this the answer has been specially elaborated by Herbert Spencer. His essential principle or Law of Evolution must be stated in his own words: 'Evolution is an integration of matter and concomitant dissipation of motion during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation.' The deductive and inductive establishment of this principle, and its comprehensive verification and fruitful application throughout the fields of the higher sciences as well, are necessarily left for fuller separate exposition (see SPENCER). And although the student who seeks to follow Spencer in grappling with the riddle of evolution in higher orders of phenomena may not admit that his uncompromising application of the principles of physical evolution to higher categories is so exhaustive and satisfactory as he claims, there can be no doubt that this general treatment has been on the whole amply justified so far as it goes, alike in unifying the sciences, and in the separate organisation of these.

Evolution in Biology.—This portion of the subject demands special attention and fullest outline for many reasons. Not only is the transition from static to evolutionary conceptions of comparatively recent, indeed almost contemporary interest; but the progress of the doctrine of evolution as a general theory of the universe has been most closely connected with progress in biology. And while we can at best merely speculate as to the direct continuity of evolution from the inorganic to the organic world (see BIOLOGY, SPONTANEOUS GENERATION), we are constantly impressed by the fundamental unity of the process in the simplest and most complex forms of life, and by the thoroughness with which the same principles may be traced into the highest 'superorganic' phenomena of mind and society.

At the outset we require some such conception of

the actual historic progress of our concrete knowledge of plants and animals as is outlined in the articles BOTANY and ZOOLOGY, and also of that rise of our more abstract kinetic and static (physiological and morphological) interpretations of the phenomena of life as is given under BIOLOGY and BOTANY. The general argument for evolution appended by Darwin to the classic statement of his theory of Natural Selection in the *Origin of Species* has been already summarised under DARWINIAN THEORY, and its separate heads are also to be found under separate articles; only the briefest reference to these need here be made. We must keep, for instance, in view the conceptions of the actual evolution of the individual which have become systematised in the sub-science of embryology (see EMBRYOLOGY). Suffice it, however, here to recall that, although it is in this connection that the term *evolution* first makes its appearance, it is used along with *development*, in a sense diametrically opposed to its present significance, as the mere enlargement and unfolding (*evolutio*, *evolution*, *Entwicklung*) of a form and structure in all essential respects a perfect miniature of that of the adult.

Without recording or analysing the various conceptions of species (see SPECIES) it is sufficient again to note how the belief in their objective constancy and practical definableness is shaken by such facts as (1) that pre-evolutionary systematists differ hopelessly upon the number and limits of the species of all the more variable groups of plants and animals; (2) that the mere numerical increase of the number of specimens in our museums is constantly compelling us to recognise that great numbers, sometimes even scores or hundreds, of 'type-specimens' of irreproachably described 'species' are but so many individual members of a series linked by the most infinitesimal gradations, yet of which the extremes differ by characters of specific, it may be even generic rank. And when (3) the assumption of the general sterility of hybrids is proved experimentally (see HYBRID) to be an exaggeration, it becomes, to say the least, increasingly difficult seriously to support the dogma of the constancy of species.

Leaving the general external form with which the species-maker is mainly concerned, we must accompany the anatomist through each level of his deepening analyses and comparisons, through organ-systems and organs, tissues and cells, to the ultimate protoplasm itself (see BIOLOGY, MORPHOLOGY). To realise how fully this analysis results in the demonstration of an unsuspected unity of structure not only between species and genera, but far larger groups, some actual study of the concrete facts is indispensable; as also to appreciate the same beautiful unity of type in individual structures so differentiated as the appendages of a lobster (see CRUSTACEA) or the parts of a flower (see FLOWER). Yet here again we have an instance of the tenacity of static conceptions; for although it could not be actually denied that the hypothesis of descent from common ancestors at least *might* explain the structural unity observable under classification, as from a simpler ancestor, that observable under the individual structure, the conception of conformity to a purely ideal 'archetype,' was long maintained. Rudimentary organs, such as the teeth of foetal whales, were thus explained not as reduced survivals of structures ancestrally useful, but as purely intellectual necessities of this arbitrary 'conformity to type.' This ingenious revival of Platonic ideas in conjunction with scholastic nominalism could not, however, very long survive the demonstration of the frequent absence of rudiments necessary for archetypal purposes; and the alternative evolution-

ary explanation has thus inevitably succeeded to its place.

It is much to learn from the taxonomist that his classification of species and genera, even the whole world of plants or animals, assumes the form of a vast genealogical tree; and it is no small confirmation of the evolutionary view to note how every new fossil-trove throws some fresh light upon the order in which the branches or branchlets of this tree have historically developed. With all the missing links we can imagine or desire between the modern horse and his simple five-toed ancestor (see PALAEONTOLOGY, FOOT, HORSE), not to speak of other examples, we have indeed evidence which may well satisfy us of the historic fact of evolution; but this brings us no nearer comprehending the rationale of the process. Leaving the morphological sciences, we must pass with Darwin to the study of what we may call the higher physiology. Assuming what is known of the functions of the individual, we must note not only the relations of the species unit (in higher forms usually of course the pair), and so familiarise ourselves with the phenomena of reproduction and sex, of heredity and variation, breeding and relation to offspring, the results of intercrossing, the modification by environment, &c.; we must also consider the wider relations among the members of the same species, between allied species, and finally between practically unrelated ones, whether here of struggle or there of adaptation. He thus introduces us to this vast and practically new field, and gives us a glimpse of the living, whole nature in that magisterial series of volumes, which we may as it were group into a *Vita Naturæ*, complementary to the static *Systema Naturæ*, and no less epoch-making for our day than was that of Linnæus for his.

We see how natural it is that the student of biology who thus becomes an evolutionist so largely by help of Darwin, should accept the lucid and comprehensive modal explanation so vitally associated with his whole evolutionary attitude, and thus also become a thoroughly convinced Darwinian, a natural selectionist without more ado: and we can readily understand that the assent of the majority of the intelligent public should have gradually followed the same course during the generation after the publication of the *Origin of Species*.

It is necessary, however, to refer more precisely to the history of opinion both as regards the fact of evolution and the factors in the process. The history of the two questions—of the empirical fact, and of the actual mechanism of evolution—can hardly be separated, though it is of course well known that the former was virtually settled by the demonstrations of Spencer, Darwin, Wallace, Haeckel, and others soon after the middle of the 19th century, while we are still in the midst of keen debate as to the relative importance of the diverse factors. The history of the theory of evolution, so far as the organic world is concerned, is essentially modern, for in spite of vague hints and *a priori* speculations from Thales and Empedocles onwards, it was not till the 18th century that evolution began to be very definitely suggested as a modal explanation of the origin of our fauna and flora, or that inquiry began to be seriously directed to what we now call the etiology of organisms.

What was for so long only a germ-idea at length took shape in the mind of Buffon (1749), who not only urged the general conception with diplomatic skill and covert irony, but sought to show how new conditions evoked new functions, how these in turn reacted upon the structure of the organism, and how, most directly of all, altered climate, food, and other elements of the environment might be

the external conditions of internal change, whether for progress or the reverse. Erasmus Darwin (1794), with a truly living conception of nature, emphasised the organism's inherent power of self-improvement, the moulding influence of new needs, desires, and exertions, and the indirect action of the environment in evoking these. To Treviranus (1802-31) organisms appeared almost indefinitely plastic, especially, however, under the direct influence of external forces, nor did his analysis of possible factors fail to recognise what Brooks, Weismann, and others have since elaborated, that the union of diverse sexual elements in fertilisation was in itself a fountain of change. His contemporary Lamarck (1801-9) is well known to have emphasised the importance of changed conditions in evoking new needs, desires, and activities, while urging also the perfection wrought by practice and the degeneration which follows as the nemesis of disuse. Evolution seemed to him the interaction of two fates—an internal progressive power of life, and the external force of circumstances in the twofold struggle with the environment and with competitors. Among the philosophers also, especially in the minds of those who had been disciplined in physical or historical investigations, the speculations of the ancients were ever taking fresh form, gaining moreover in concreteness; witness the contributions of Kant and Herder. In Goethe's epic of evolution the adaptive influence of the environment is clearly recognised, while the misty theories of his contemporary Oken chiefly interpret the organic progress in terms of action and reaction between the organism and its surroundings. Wells in 1813 and Patrick Matthew in 1831 forestalled Darwin in suggesting the importance of natural selection, but their buried doctrines were of much less practical importance than those of Robert Chambers, the long unknown author of the *Vestiges of Creation* (1844-53). His hypothesis of evolution emphasised the growing or evolving powers of the organisms themselves, which developed in rhythmic impulses through ascending grades of organisation, modified at the same time by external circumstances acting with most effect on the generative system. In France, Geoffroy and Isidore St Hilaire, father and son, supported the thesis of definite variation under direct environmental influence. And before reaching even the contemporaries of Darwin a complete history would have to take account of the conclusions of many naturalists, such as Von Buch, Von Baer, Schleiden, Naudin, and Wagner. The environmental factor was subsequently recognised with greater clearness and with less exclusiveness by Spencer; while Darwin and Wallace, recognising some truth in most of the above positions, but believing them wholly insufficient, left the problem of the origin of variations alone, and devoted their strength to establishing the theory of the origin of species by means of natural selection, a view which emphasises the destructive or eliminating and the conservative or selective action of the animate and inanimate environment in the struggle for existence.

Even from the above brief sketch of representative conclusions, it will be seen that successive authors accent diverse factors in the evolutionary process: in the view of one the organism has a motor power of variation inherent in its very constitution, or gained by the intermingling of sex-elements from which the individual life starts; to another the moulding power of changed function, the perfecting influence of exercise, the degenerating nemesis of disuse are all important; while to a third organisms seem to have been hammered from one shape into another by the action of that complex series of external influences which we briefly term the environment. Among modern

naturalists we find champions of each of these three positions respectively emphasising (a) the organism itself, (b) its function, and (c) its environment; a few remain more or less exclusive Natural Selectionists, with or without theones of the origin of the variations which they postulate; while the majority more and more incline to an eclectic but not yet synthetic view, differing chiefly in regard to the relative importance of the various factors recognised.

The difficulty will be obvious of even briefly discussing so many positions, many of which are better dealt with under the separate articles ENVIRONMENT, HEREDITY, REPRODUCTION, SEX, VARIATION; and it is undesirable here to stereotype any one position as final during an unended controversy. That criticism will be certainly more temperate, and probably not less fruitful, which for a time seems to withdraw from the actual field of battle; which, instead of joining issue on this point or upon that, seeks rather to recognise all the leading points of view from which the subject may be approached, and thence to clear up the various lines on which a modal explanation is or may be offered, or to which it must at anyrate be capable of satisfactory application. We should thus even be able to do more justice to the older naturalists' positions.

Evolution in Psychology.—The psychologist admits the same inability to derive psychical processes and states from the nutritive and reproductive functions and structures which form the subject-matter of biology that the biologist does to derive these from inorganic processes. This fact does not of course interfere with the investigation of the parallelism of each of these higher orders of phenomena (see BIOLOGY), still less with the detailed study of evolution in mind, for which, as Herbert Spencer especially demonstrated, evolution in the preliminary sciences of biology and physics is so suggestive. What most concerns us here is to note how largely the science of psychology, or what stood for it, was wont to be a matter of deduction from that time-honoured axiom that human nature is for practical purposes always and everywhere the same; which, as evolutionists, we now see to have been an erroneous postulate. The older psychology was concerned especially with less or more scientific analyses of the adult mind, and this usually of the isolated 'typical' one (usually of the psychologist himself), but in a form too generalised to admit of much practical application. The modern school recognises the necessity of unravelling the vast complexity of the actual details of psychical processes, and not only eagerly investigates the development of the infantile mind, but scrutinises the kindred though humbler phenomena of animal cerebration. Psychology is drawing new light from the long discredited study of hypnotic states (see ANIMAL MAGNETISM); since here psychical functions can be analysed at various levels, and this apart from the perturbing action of the will. Again, it finds a rich source of knowledge in those morbid variations towards excessive or deficient cerebration and neurulation which we group under the complex term Insanity (q.v.). Yet that it reaches also the most complex concrete products of evolution is evidenced by the rise and progress of criticism in literature and art. That we have here the closest parallelism to biology and its progress is manifest, as our current phrases of comparative psychology, of mental physiology, pathology, variation, and the like clearly show. We see, indeed, that the science of psychology is now more biological, more evolutionary, and more unified than biology itself, which is still so largely limited by the numerous and confused dispersive and analytic specialisms from which it has arisen, and which it

is still so far from having reorganised. The transition from the static to the kinetic attitude is thus more nearly complete. The debt of science to practice is here obvious in the gain from education and mental hygiene; while the return of the science into practice, as yet only incipient, promises results of the vastest kind. Education would at length have to be viewed and practised in an evolutionary sense, as the process of assisting the entire development of the individual into, it may be beyond, the actual living powers, into the stature and beauty, of the race; instead of smothering the development under the mere accumulation of its dead results in certain fields of detail. Nor is the parallelism of psychical and physiological processes, which enables us to modify more and more mind through body, failing to open up subtler possibilities of modifying body through mind.

Evolution in the Social Sciences.—Leaving fuller treatment to the article SOCIOLOGY, and such special articles (POLITICAL ECONOMY, &c.) as are therewith connected, we may note that the social science of the pre-evolutionary period, although represented on its concrete side by history, and its abstract side especially by political economy, was essentially static. History was necessarily a record of occurrences at specified dates, which, although sometimes set forth in their minor relations of cause and effect, did not admit of any large co-ordination in scientific terms; though the continual attempt by theologians and metaphysicians to construct a philosophy of history indicated at least the need of this. Upon the abstract side we have those attempts to formulate a purely deductive 'science of political economy,' which still so largely survives; although its pretended laws, deduced from postulates of the archaic psychology, such as that of action exclusively arising from self-interest, or from metaphysical abstractions such as utility, are now being replaced by generalisations drawn from the inductive study of social phenomena, actual and historic, and by principles firmly established in the preliminary sciences. The derivation of our whole body of social knowledge from social practice is here of course absolute, all the phenomena being human ones; and the reaction of theory upon practice can only at first sight seem disproportionately small when we lose sight of the importance of the past thought systematised in legal and religious systems. In the world of material interests static views have as yet essentially prevailed: witness the incomparable antiquity of law as compared with that of the modern process of law-making and unmaking which we call internal politics—a form of activity which, however disappointing in its practical results, has at least had something to do with the even more recent emergence and popularisation of the idea of social progress. This characteristically modern idea became increasingly systematised, on the one hand through special studies, and on the other through the unparalleled progress of the mechanical arts. We must note also that the recent foundation of sociology as a distinct and unified science depended upon the attainment of a synthetic interpretation of the history of western Europe both material and intellectual as the central process of the general evolution of humanity; while no subsequent labours on behalf of the nascent science have been greater than those of that later thinker who has been as much concerned as any other with the general philosophy of evolution.

That the idea of evolution has originally been projected from the social plane into that of the other sciences, is a proposition which can only be doubted by the specialist who has not inquired

into the history of his ideas; evolution in social affairs has not only suggested our ideas of evolution in the other sciences, but has deeply coloured them in accordance with the particular phase of social evolution current at the time. The hermit not unnaturally supposes his cosmist meditations to be wholly unspotted by the world he has left behind, but this cannot prevent the historian from rigorously viewing his whole thought and conduct as a product of that world. Nor is absolute demonstration difficult even from the strictest biological specialist's own postulate—that life is interpretable merely as a biological phenomenon. Be it so: then science is the summed (phylogenetic) experience of the race, and the investigator's contribution to it is of course measured by his own development (ontogeny). But the development of an organism, functional and cerebral, is so far *pari passu* with its adaptation to the world around it, but still more in relation to its own species. In other words, the measure of individuation attained by the individual of any species as compared with its fellows is dependent in the first place upon sexual maturity, (2) upon the relations to offspring towards which this tends to develop, and (3) upon the measure of sociality which in so many species arises through the widening of this direct reproductive relation into that of a larger aggregate. This is a proposition which the biologist should be the last to dispute; hence, while arguing for the evolution of the human species by the same agencies which have shaped the lower ones, it is impracticable permanently to retain the absurd assumption, inherited from pre-evolutionary psychology, that mental development goes on as it were in *vacuo*, without reference to the expansion of the organic functions of self-maintaining and species-maintaining. But as this survival becomes outgrown the pure biologist will of course be the first to emphasise and elaborate the proposition that all human developments, like those of any other species, are in terms of these.

Modal Explanation of Organic Evolution.—The conception thus reached of the measure of evolution of a species being expressible in terms of the progress of its (1) self-maintaining and (2) species-maintaining functions is equally capable of statement in biological, psychological, sociological, or indeed also, as moralists are now agreeing (see ETHICS), in ethical terms; what are termed egoistic or altruistic actions being respectively self-maintaining or species-maintaining ones, of course at different levels of evolution. Here, then, we have a basis for the required inquiry as to the mechanism of the evolutionary processes. The evolutionist at any rate will not dispute this parallelism between the non-ethical aspects of organic evolution, nor deny that the results and processes of evolution in their highest manifestations may be of service in elucidating or criticising the similar ones which must be supposed to exist in less developed forms. Hence he would be in some respects even better justified in tracing the evolutionary process down from the highest aspects to the more simple ones, and from the human species to humbler ones, than conversely: thus the limitations of the doctrine of natural selection may be better understood, and this on two or three distinct sides. It is not altogether easy to meet the criticism sometimes urged by the economist that the process which kills off the weakest of the race weakens and deteriorates those which survive, and that, while some struggle for existence is needful for individuation, human progress is yet observably associated with an advance of the subsistence fund over the requirements of maintenance. Without

insisting upon the difficulties urged by Wallace, Mivart, and other evolutionists as to the descent of man (see MAN, DESCENT OF), the ethical difficulty so common to all inquiries respecting evolution and natural selection in general, but human evolution in particular, cannot be escaped. For we have as yet little beyond the cheerful optimism which sets off the cumulative gain to the species against the incessant sacrifice of the weak to the strong which is in constant progress alike in nature and in human society. And if this be indeed the spring of human progress, how can we resist the logic which calls upon us to remove those adjustments for the mitigation of the struggle for existence for the protection of the weaker, with which, however, not only our feelings and what we have been accustomed to call our higher instincts, but our whole civilisation, material and moral, are inextricably bound up? A classical statement of the central difficulty, of which the Darwinism and the morals are alike unexceptionable, and the resultant dualism therefore clearly set forth, may be quoted from Huxley: 'From the point of view of the naturalist the world is on about the same level as a gladiator's show. . . . We must say that its governing principle is intellectual, and not moral, that it is a materialised logical process accompanied by pleasures and pains. . . . Society differs from nature in having a definite moral object. . . . The ethical man tries to escape from his place in the animal world founded on the free development of the principle of non-moral evolution, and to found a Kingdom of Man, governed upon the principle of moral evolution. For society not only has a moral end, but, in its perfection, social life is embodied morality. But the effort of the ethical man to work to a moral end, by no means abolished, perhaps has hardly modified the deep-seated organic impulses which impel the natural man to follow his non-moral course.'

The natural selectionist sometimes seeks (as Darwin indeed himself did) to escape this frank return to a pre-evolutionary ethical dualism by reminding us that, since on his view 'nature trusts to the chapter of accidents for variation,' favourable ethical variations may spontaneously have arisen at the static plane. But even if the dawn of similar variations in lower species did not raise a probability of the definite rather than fortuitous nature of such variations, the unity of all the four aspects of organic evolution is none the less given up.

The theory of natural selection is now, however, itself undergoing an evolution which promises fair for an escape from these difficulties, and this on all hands. In its classic form it assumed selection to operate upon an indefinite number of individual variations, which Darwin, at least in some moods, was quite ready to admit might be produced by environment, increased by function, and the like; but which, once selected, were preserved by heredity and frequently increased by new spontaneous variations in the same direction. Now, however (see HEREDITY), we have an ultra-Darwinian school founded by Weismann, and followed by Lankester and many others, which, denying the heredity of acquired characters, pushes back the origin of all variations of species-making importance into the protoplasm of the sex-elements, and so seems to leave natural selection as the only factor of evolution which we can really hope intelligently to grasp, variation seeming inscrutable. The neo-Lamarckian school, on the other hand, with which Spencer must also be reckoned, holds a very different doctrine, that of the importance of individual function and the transmission of its modifications; while the influence of environment is also coming

to be studied with not only speculative acuteness but experimental detail. Variation is again being more and more frequently regarded as taking place on a few definite lines; and the origin of species is viewed as a literal development of internal conditions in the species as in the development of the individual, which environment can only bend and colour, and natural selection no more than prune. Such views (see VARIATION), too often formulated with excessive generality and indeed vagueness, yet on the whole with increasing concrete application to detail, are maintained by Nageli, Cope, Eimer, and many others, including the present writer. It will at anyrate be recognised that there is ample room for such inquiries, and that the importance claimed by natural selection cannot be safely established until they have been disposed of in favour of that hypothesis of indefinite variability upon which this importance essentially depends. It is becoming more and more apparent that it is the problem of variation which is fundamental to selection.

Amid so many various opinions Dr Wallace came to stand almost alone as an avowed exponent of the theory of natural selection in its classic form; yet even he not only made the reserve as to human descent above alluded to, but sought to replace Darwin's sexual selection (see SEX) by a new hypothesis, and so enlisted the services of that heresy of definite variation which is so irreconcilable with Darwin's general argument.

The general drift of the contemporary discussion has thus become more apparent; all theories and criticisms have hitherto started with the individual as the unit, and the origin and differentiation of the self-maintaining structures and functions as the primary problem; after which the origin and differentiation of reproductive and species regarding processes have been left only a secondary and subsequent place. But we are beginning to discover that this method of approach, however natural to the individual thinker, is artificial as respects nature; we have above been noting how many different lines of research are turning from the self-maintaining to the species-maintaining process; and the centre of gravity of the science is in fact undergoing a revolutionary change. In thinking of a species we have been wont to call up and investigate the individual type, and to recognise the process of reproduction subsequently only as giving us a less or more varied repetition of this type; but this is a survival of the static and anatomical view. What the general physiologist is now coming to recognise in the species, and what accordingly the evolutionist *a fortiori* must keep in view, is primarily its living continuity, no longer the details of its separate links. From this most general point of view both are coming to see the most complex individual lives, in Foster's phrase, as but the 'by-play of ovum-bearing organisms.' The species is a continuous undying chain of unicellular reproductive units which indeed build out of and around themselves transient multicellular bodies; but the processes of nutritive differentiation and other individual development of these is the secondary, not the primary question.

Instead, therefore, of beginning with the origin and adaptation of the details of self-maintaining advantage, coming later to those of reproduction and sex, and only recognising the mysterious control of the principle of correlation of organs in the background of the whole process, as Darwin and other evolutionists have been wont to do, a fuller initial recognition of the reproductive process raises the question of correlation between the reproductive and individual functions at the outset. We see the sexual development of animal, and still more obviously of plant, everywhere becoming a most

potent determinant of its adult character, and one of classificatory importance far deeper than the mere individual characteristics of the separate species. We see again how the nature and degree of relation to offspring gives a new key to the larger aspects of classification. Thus it is the central generalisation of botany that despite the individual differentiation of fern, selaginella, cycad, conifer, and flower, these turn out on deepest analysis to be but the surviving phases of a continuous and definite increase in the subordination of the sexual parents to their asexual offspring (see FLOWER). Or in the same way, while we define the orders and sub-orders, genera and species of the mammalia by help of the individual apparatus for maintenance or struggle, the larger question of the characteristics of the mammalia, and of their main subdivisions, does not depend upon any mere accumulation of these, as Darwin's very natural application of Lyell's well-known argument would require: for not only the mammal but its essential types, monotremes, marsupial and placental, and even again the subdivisions of the latter, express so many stages in the progress of maternal sacrifice for offspring. In the same way with the evolution of sociality which arises from reproductive aggregation in so many species, we see this subordinating struggle, greatly facilitating not only the increase in numbers of the species, but their higher specialisation as well. We escape from the conception that progress depends primarily upon internecine struggle for existence—i.e. the subordination of the species to the individual, instead of primarily upon that of the individual to the maintenance of the species in sex, offspring, and society. Thus our ethical difficulty at length disappears, since the greater steps of advance in the organic world compel us to interpret the general scheme of evolution as primarily a materialised ethical process underlying all appearance of 'a gladiator's show.'

The corresponding progress in the historic and individual world from sex and family up to tribe or city, nation and race, and ultimately to the conception of humanity itself, also becomes increasingly apparent. Competition and survival of the fittest are never wholly eliminated, but reappear on each new plane to work out the predominance of the higher, the more integrated and associated type; the phalanx being victorious till in turn it meets the legion. But this service no longer compels us to regard these agencies as the essential mechanism of progress, to the practical exclusion of the associative factor upon which the victory depends, as economist and biologist have too long misled each other into doing. For we see that it is possible to interpret the ideals of ethical progress—through love and sociality, co-operation and sacrifice, not as mere utopias contradicted by experience, but as the highest expressions of the central evolutionary process of the natural world. To continue the generalisation of the process of evolution, organic and super-organic, which Spencer, repeating on a higher spiral the thought-cycle of many an earlier thinker, reopened, is to raise anew all the problems of philosophy. The evolutionary reorganisation of thought implies the leavening of art and practical life.

See books cited at DARWINIAN THEORY; articles on the subjects above mentioned, particularly CELL, EMBRYOLOGY, HEREDITY, MIMICRY, PROTOPLASM, and VARIATION; those on special authors, as HAECKEL, HUXLEY, LAMARCK, SPENCER, WALLACE (A. R.), WEISMANN, &c.; also Romanes, *Darwin and after Darwin* (1892-95); H. F. Osborne, *From the Greeks to Darwin* (1894); Weismann, *The Evolution Theory* (trans. 1905); Jordan and Kellogg, *Evolution and Animal Life* (1907); Kellogg, *Darwinism To-day* (1907); Poulton, *Essays on Evolution* (1908); *Darwin and Modern Science*, by various authors (1909); Geddes and Thomson, *Evolution* (1911).

Évora (ancient *Ebora*), one of the most interesting cities of Portugal, capital of the province of Alentejo, is charmingly situated on a fertile and well-cultivated plain, 72 miles E. of Lisbon by rail. It is surrounded by ancient walls long since in a hopelessly ruinous condition, and to some extent by modern fortifications as yet unfinished. It is a very ancient city; Quintus Sertorius took it in 80 B.C., and it was also conquered by the Moors in 715, but recovered from them in 1139. Among the supposed Roman antiquities of Évora are the temple of Diana, with fine Corinthian columns; an aqueduct said to have been erected by Quintus Sertorius, and rebuilt in the 16th century, which till recently supplied the city with water; and the beautiful tower, surrounded by Ionic columns, which rises in the city at the extremity of the aqueduct. The aqueduct and the tower have been partially demolished. The town itself is not well built, and the streets are narrow, winding, and dirty. It has a cathedral, founded in 1186, and afterwards restored in the Gothic style. It has been the see of an archbishop since 1540, and has an archiepiscopal library, containing several pictures of great merit. There are some manufactures of cotton, cloth, and hats, and a trade in wine. Pop. 16,000.

Évremond, CHARLES MARGOTELLO. See SAINT-ÉVREMOND.

Évreux (ancient *Mediolanum*, late: *Ebuovices*), the capital of the French department of Eure, is situated in the fertile valley of the Iton, a feeder of the Eure, 67 miles by rail WNW. of Paris. The cathedral, of various dates from the 11th to the 18th century, is a cruciform structure, with Italian façade, a central spire, and fine painted glass. Other buildings are St Taurin's, with a 13th-century shrine, which once contained the relics of that saint, the first Bishop of Évreux; the episcopal palace (1484); and the 'Tour de l'Horloge,' of the same century. Évreux has extensive manufactures of paper, linen, &c., and a trade in grain, seeds, timber, and liquors. Population about 18,000. Évreux has sustained innumerable sieges, having been sacked in 892 by the Northmen under Rollo, burned by Henry I. of England in 1119, and in 1194 and 1199 captured by Philip Augustus of France. It was frequently taken and recovered in the wars between France and England during the reigns of our Henry V. and VI.—At the neighbouring village of VIEIL ÉVREUX, supposed to mark the site of *Mediolanum*, excavations have disclosed remains of a theatre, an aqueduct, baths, &c.

Ewald, GEORG HEINRICH AUGUST VON, the famous Orientalist, was born 16th November 1803, at Göttingen, where his father was a cloth-weaver. From 1820 he studied at the university, under Eichhorn, theology and philology, devoting himself especially to the oriental languages; in 1823-24 he was a teacher at the gymnasium at Wolfenbüttel; in the latter year he published his first work, *Die Komposition der Genesis*, and was appointed a theological tutor in his own university of Göttingen. After this he became in 1827 an extraordinary professor, and in 1831 ordinary professor of Philosophy, and in 1835 nominal professor of Oriental Languages. For his share in the protest of the seven Göttingen professors against the annulling of the Hanoverian constitutional law he was deprived of his chair by a rescript of the 12th December 1837; and after spending some months in England he was called to a chair at Tübingen, where he remained for ten years and a half. He was ennobled by the king of Württemberg in 1841, and in 1848 was recalled to Göttingen, where he spent the remainder of his life. In consequence of his refusal to take the oath of allegiance to the

Prussian government, he was at his own request pensioned off in 1867. His earlier works, chiefly devoted to the grammar and metres of the oriental languages, include *De Metris Carminum Arabicorum* (1825), *Versuch über einige ältere Sanskritmetra* (1827), *Grammatica Critica Linguae Arabicae* (2 vols. 1831-33), and his *Kritische Grammatik der hebraischen Sprache* (1827), which he reproduced in an abbreviated form in his *Grammatik der hebraischen Sprache* (1835, 3d ed. 1838), and with greater fullness of detail in his *Ausführliches Lehrbuch der hebraischen Sprache* (8th ed. Gott. 1870). The scientific results of his travels are partly contained in his *Abhandlungen zur orientalischen und biblischen Litteratur* (1832), and in his *Zeitschrift für die Kunde des Morgenlandes*. The rich fruit of his lifelong study of the Old Testament is stored in *Die Dichter des Alten Bundes* (2d ed. 3 vols. 1866-67; Eng. trans. of Psalms, 2 vols. 1880-81, of Job, 1882), *Die Propheten des Alten Bundes* (2d ed. 3 vols. 1867-68; Eng. trans. 5 vols. 1875-81), *Beiträge zur Geschichte der ältesten Auslegung und Spracherklärung des Alten Testaments* (3 vols. 1844), and finally in his magnificent masterpiece, *Geschichte des Volkes Israel* (3d ed. 7 vols. 1864-68; Eng. trans. in 8 vols. 1867-86), with the supplement, *Die Alterthümer des israelitischen Volkes* (3d ed. 1866; Eng. trans. 1876). To the study of the New Testament Ewald contributed his *Jahrbücher der biblischen Wissenschaft* (12 parts, 1849-65), *Die drei ersten Evangelien* (1850), *Die Sendschreiben des Apostels Paulus* (1857), *Die Johanneischen Schriften* (2 vols. 1862), *Uebersetzung und Erklärung aller Bücher des Neuen Testaments* (7 vols. 1870-72). Of his other works the most noteworthy are his *Erklärung der grossen phönizischen Inschrift in Sidon* (1856), *Ueber die phönizischen Ansichten von der Welterschöpfung* (1857), *Die Silyllunischen Bücher* (1858), *Das vierte Ezerabuch* (1863), *Sprachwissenschaftliche Abhandlungen* (1861-71), *Abhandlung zur Zerstreung der Vorurtheile über das alte und neue Morgenland* (1872), *Die Lehre der Bibel von Gott* (3 vols. 1871-75). In his scientific studies, Ewald followed his own way. His hand was against every man, and he was impatient of contradiction. He was an equally vigorous adversary of the 'Tübingen School' and of the orthodoxy of Hengstenberg and Delitzsch. In the prefaces and postscripts of his books, and in his year-books for biblical science, he frequently took occasion to express his uncompromising views on the political and ecclesiastical questions of the day, and frequently shows an entirely unjustifiable severity in criticising those from whom he differed. From 1869 he represented Hanover in the Reichstag, and was a decided opponent of the ambition of Prussia. He died of an affection of the heart, 4th May 1875. An autobiography, which he wrote in the last months of his life, remained unpublished. A monument was erected by his disciples over his grave at Göttingen. Ewald brought to the interpretation of the Hebrew prophets a spirit akin to their own—Hase describes him as a prophet with backward gaze. His patriotism and courage, his poetic fire and energy, his spiritual insight and marvellous power of sympathetically reproducing primitive experiences by the divinations of genius, and the indefatigable industry with which he applied his perspicacity and insight to understand the Hebrew nation and its sacred literature have secured for him the highest place among the biblical scholars of his century. See two admirable critical papers on the life and work of Ewald by Professor Cheyne, in the *Expositor*, third series, vol. iv. (1886).

Ewald, JOHANNES, a Danish poet, was born 18th November 1743, at Copenhagen, where his father was a pastor of the strictest pietistic views.

Before his father's death he went to a school at Sleswick, from which he ran away to seek an uninhabited island like that of Robinson Crusoe, but did not get farther than Hamburg. In 1758 he began to study theology at Copenhagen. His love of adventure led him to Magdeburg, where he entered an infantry regiment. He soon deserted to the Austrian army, in which he was first a drummer, then an under-officer. After taking part in several engagements in 1759-60, he obtained his discharge, and returned to theological study at Copenhagen. A disappointment in love was the turning-point of his life. After this he gave his attention solely to poetry. To this also he attributed the irregularities of his life, which bore bitter fruit in the poverty and ill-health of his later years. The allegorical poem, *Lylckens Tempel*, published in 1764, was well received; but it was not till two years later, in his elegy on the death of Frederick V., that he gave clear proof of his lyrical power. The biblical drama, *Adam og Eva* (1769), shows clear traces of the influence of Klopstock. His other writings include a series of satiric plays; the prose tragedy, *Rolf Krage* (1770); and the two masterpieces, *Balders Dod* and *Fiskerne*, the latter containing 'Kong Christian stod ved højen Mast,' which has become the national song of Denmark. He died on the 17th March 1781, leaving an incomplete autobiography, *Johannes Ewalds Løvet og Meninger*. Though he was scarcely thirty-eight years old at his death, Ewald's work has taken a pre-eminent part in the development of Danish literature. Oehlenschläger has testified in some of his finest poems that Ewald was the creator of the modern poetry of Denmark. As Holberg was the father of Danish comedy, so Ewald was the founder of Danish tragedy. Yet his noblest productions are his lyrical poems and odes, the pure beauty of which is scarcely to be surpassed. The best edition of his works is that of Liebenberg (8 vols. Copenhagen, 1850-55). See the *Lives* by Hammerich (1860) and Dolleris (1900).

Ewell, RICHARD STODDERT, Confederate soldier, was born in Georgetown, D.C., in 1817, served in Mexico and against the Apaches, and was actively engaged throughout the civil war. In 1862 he fought with distinction under Jackson, losing a leg near Bull Run in August; and, having been promoted lieutenant-general, he served gallantly at Winchester, Gettysburg, and the Wilderness. At Sailor's Creek, however, he was captured, with his entire force, 6th April 1865. He died 25th January 1872.

Ewing, JULIANA HORATIA ORR, writer for children, was the daughter of the Rev. Alfred Scott Gatty and his wife, Margaret Gatty (1809-73), the author of *Parables from Nature*, &c. Born at Ecclesfield, Yorkshire, in 1841, she early began to compose nursery plays for her brothers and sisters, which were performed with her brother, Alfred Scott Gatty, as musical conductor. But she also became proficient in her youth in the modern languages and classical literature. Her nursery stories are said to have suggested to her mother the starting of *Aunt Judy's Magazine* (1866), to which Mrs Ewing became a contributor. After Mrs Gatty's death, she edited the magazine with her sister for a time, and published in it many of her charming stories. These include *Mrs Overtheway's Remembrances*, *Jackanapes*, *Jan of the Windmill*, *A Flat Iron for a Farthing*, *We and the World*, *Lob-lie-by-the-Fire*, *Six to Sixteen*, *A Great Emergency*, *Old-fashioned Fairy Tales*, and *The Story of a Short Life*. In 1867 she had married Major Alexander Ewing, the author of a number of translations from the Turkish and the German. She died at Bath, 13th May 1885. See *Juliana Ewing and her Books*, by Horatia Gatty (1885).

Ewing, THOMAS, American statesman, was born in Virginia in 1789, and in 1816 was admitted to the Ohio bar, of which he afterwards became the unquestioned leader. He sat in the United States senate in 1831-37, was secretary of the treasury in 1841, and in 1849-50 organised the newly-created department of the interior, afterwards returning for a time to the senate. He died at Lancaster, Ohio, 26th October 1871.

Exanthemata (from a Greek verb, 'to effloresce,' or come out in a rash), a class of febrile diseases (see FEVER) attended by distinctive eruptions on the skin, appearing at a definite period, and running a recognisable course. To this class belong smallpox, chicken-pox, measles, scarlet fever, typhoid, roseola, erysipelas, glanders, dengue, and cerebro-spinal fever.

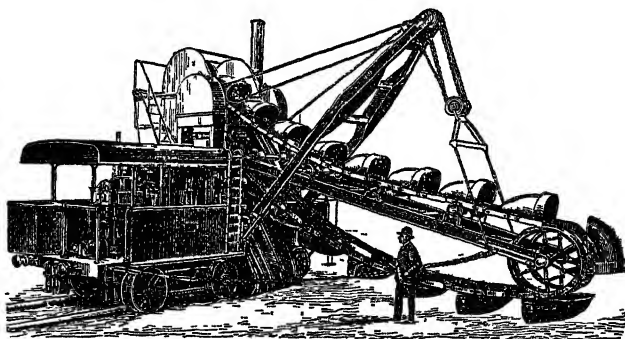

Exarch was the title conferred by Justinian on his commander-in-chief and vicegerent in Italy, Narses, who reconquered Italy from the Goths (554). The seat of the exarchs was Ravenna. The extent of the *exarchate* was gradually diminished until it embraced only the country about Ravenna (q.v.). This was brought about by the conquests of the Longobards, whose king, Astulf, in 752 put an end to the Byzantine rule at Ravenna; but in 755 he was compelled to resign the exarchate to Pepin, king of the Franks, who gave it over to the Bishop of Rome, Stephen II.—Other Byzantine viceroys were called exarchs; and the title was conferred on certain archbishops, especially the head of the Bulgarian Church. The Bulgarian exarchate was removed in 1913 from Constantinople to Sofia, and the exarch was housed in the palace of the Holy Synod. See GREEK CHURCH.

Excalibur, the famous mystic sword of King Arthur, which was given him as Merlin promised by the Lady of the Lake, and at his death was flung into the river and caught up by a hand which rose above the waters.

Excambion (from the same source as 'exchange'—Lat. *campère*, 'to barter'), in Scotland, is the legal name of the contract whereby one piece of land is exchanged for another. The contract usually gives to the parties the right to recur to the original property in case of eviction from the land excambied. Heirs of entail may, with the same consents as are necessary to enable them to disentail, excamb all or any portion of the entailed estate. Where excambied lands are burdened with debts, they are freed of these by the excambion, and burdened with the debts previously affecting the lands acquired in exchange for them. See EXCHANGE (DEED OF).

Excavators. These machines have been brought into use in the making of docks, railway-cuttings, canals, &c. Excavators are made of two kinds, each adapted for different kinds of work, although in some cases they work together very effectively. In making a long 'gullet' or cutting, the first to come into operation has the appearance and all the functions of the ordinary steam-crane, such as is used for loading railway trucks, with the exception that it is mounted on wheels to move on rails, and that, instead of the hook on the end of the chain, there is a large and strong plate-iron bucket or 'scoop,' with a very heavy handle or lever to which a second chain is fastened. The lever is heavy enough to counterbalance the scoop when filled with clay. The machine begins by lowering the scoop, and

the two chains are made to push it into the bank until it is full. The suspension chain then lifts the scoop over the wagon, while the chain on the handle lifting it up empties it. The machine now swings round on its centre to renew the operation. The largest size can excavate two cubic yards per minute. As the excavator advances over its rails, those behind are brought to the front. The cutting is made as wide as the arm or 'jib' will reach on both sides of it, which leaves sufficient room for the men to work round it freely, and for wagons to pass. When the cutting has been made the requisite distance forward, the second class of excavator (shown in the engraving) is brought forward to make the cutting wider. The original conception of this is clearly derived from the Dredger (q.v.), which has long been in use in deepening harbours and the mouths of rivers. Its sides are made sloping to an angle of 45 degrees, and on the top of the bank a temporary line of rails is laid a few feet from the edge. The machine is placed on the rails at

Steam Excavator.

the end of the cutting; the jib is lowered until the row of buckets it carries can cut into the clay; these scrape up the bank, reaching the top of it full of soil; they next pass over the machine, and are emptied into the wagons beyond it. The excavator and wagons move forward simultaneously, the latter receiving, in the case of some excavators, a continuous stream of clay equal to about four cubic yards, or two wagon-loads per minute. It will be evident from the foregoing explanation that the first kind of machine is best adapted for docks, and preparing the way in long and deep cuttings for the second kind to follow. It may be said that the first will perform a greater variety of operations, while the second cannot be surpassed in the quantity of material it will remove in a given time. All the movements of excavators are effected by the power of the engine, and two men manage each machine.

Excellency, a title now given to Ambassadors (q.v.), as representing not the affairs alone, but the persons of sovereign princes, to whom it was formerly applied.

Exchange, in Political Economy, is based on the elementary fact that we are ready to give what we do not want for what we do want, or what we want less for what we desire more. Even in very old communities we find a considerable exchange. As soon as the primitive division of labour into agriculturist, weaver, smith, and carpenter was established, there must have followed a mutual exchange of the produce of these callings. But the early exchange was practicable only under very restricted local conditions, for the means of transport and communication were for long not suffi-

ciently developed to convey the staple commodities of industry over very great distances. Indeed, until the means of transport and communication were revolutionised by steam and electricity, all articles that have a considerable weight and bulk in proportion to their value were in general consumed at the place where they were produced. The grain was ground at the village mill, and consumed by those who had produced it; the village smith attended to the iron-work, the village carpenter did the same for the carpentry-work. In the village the wool was spun and woven into cloth, which in general was worn by the people of the locality. The village, parish, or district was an economic unit, within which the business of exchange was for the most part confined.

On the other hand, there had existed from very early times an exchange on a wider scale of commodities which possess a high value in proportion to their bulk and weight, and which are not readily perishable. Gold and silver, precious stones, spices, silk, &c. were the objects of a commerce which was carried on between the Mediterranean countries and the distant East. As civilisation with the corresponding industrial development advanced along the Mediterranean, a more varied and active exchange grew up among the peoples near that great highway of early commerce. Later on it found further scope on the seas and rivers of western and north-western Europe, and along various land routes, especially on those between Italy and Germany. The discovery of America and of the sea-way to India opened up an exchange which has now become universal.

The growth of exchange has simply followed the general social and industrial development. Exchange is based on differences of soil and climate, on differences of social development, on the distinction between town and country, on the growth of the division of labour—in fact, on the wide organic development of the great human society over the different areas of the world. It has particularly depended on the improvement of the means of transport and communication, on the construction of roads and canals, on the development of navigation, and, above all, on the development of steam and electricity. The means of transport are now so perfect that heavy and bulky commodities, such as grain and coal, can be profitably carried half-way round the globe. Exchange has become a dominating principle in economics. Production is only to a very slight degree carried on by the producers for the direct supply of their own needs. Under the large system of industry now prevalent, the outlet for the consumption of any article offered by the producers of it themselves is ridiculously inadequate. Production is carried on for exchange, for a market which may be co-extensive with the world; and through the vast and intricate mechanism of that world-market the consumer obtains the supply for his needs.

The growth of a world-wide exchange has naturally led to a corresponding development of what may be called the instruments and institutions of exchange. First of these is the medium of exchange. In primitive communities we find barter, the simplest method of exchange, still extant; even in the English colonies in North America it was common during the 18th century. The exchange of the civilised world is conducted through the medium of a very elaborate currency. The business of exchange in all the miscellaneous articles known to the civilised world is most largely concentrated in the great markets and exchanges, notably those of London, New York, Paris, Berlin, and Vienna.

Exchange, which to the end of the 18th century at least was hampered by innumerable restrictions

and regulations, may now be generally described as *free*; it is managed by the free competition of buyers and sellers. But there are very important exceptions and modifications which have been indicated in the article COMPETITION.

In exchange the agreement between buyer and seller is reached by a process of bargaining, which has been called the higgling of the market. It is an adjustment of supply and demand, and ultimately of the interests of producers and consumers. The proportion in which things exchange for each other is their Value (q.v.), but this value is generally expressed in money, the medium of exchange, which is their price. But, while the value is expressed in money, exchange itself is always one of commodities against commodities.

It is an evidence of the prominence attained by exchange in the economy of the civilised world that so high an authority as Whately recommended that the science of political economy should be called *Catallactics* (from Gr. *katallassō*, 'I exchange'). The effect of such a name would be to confound the fundamentals of a science with one of its salient characteristics. Production is a more important department of economics than exchange, while distribution and consumption are fundamental. The chief end of economics is the satisfaction of human needs, production and exchange being alike subsidiary and subordinate to this.

Such is the general doctrine of political economy regarding exchange; but there are some special applications of the word that require notice. Thus, exchange is specially applied to the conversion of the money of one country into its equivalent in the money of another—as by stating the relation which French francs or German marks bear to pounds sterling. It also refers to the difference between the actual value of money, taken by the standard of bullion, in any two places with relation to each other. If in London it costs more than £100 to pay £100 in St Petersburg, the rate of exchange is against the former town, and in favour of the latter; an inhabitant of which will be able to pay a debt of £100 in London with less than £100 worth of bullion in St Petersburg. The process will be best explained by analysing it through means of simple examples. If Thomson & Co. of London buy £100 worth of wine from De la Rue of Paris, and De la Rue, on the other hand, buys £100 worth of cotton goods from Thomson & Co. of London, the two debts, *were there no others between the merchants of the same towns*, would extinguish each other, and there would be no necessity either for transmitting money or drawing bills of exchange. Suppose, however, that it is not De la Rue, but his neighbour Bonchamp who has bought the £100 worth of cotton goods from Thomson & Co., then the debts of all will be settled by Bonchamp paying £100 to De la Rue on Thomson & Co.'s account. Suppose, next, the case of De la Rue being due nothing to Thomson and Co., and Bonchamp being due them only £50, a like sum has to be otherwise found. Van Pradt of Amsterdam is due precisely this sum to Thomson & Co., while either De la Rue or Bonchamp is due the same amount to Van Pradt for a purchase of Gouda cheeses; then it is clear that the several debts can be adjusted among them without the transmission of bullion. It will cost some trouble to adjust the payments, however, and this trouble will have to be paid for. As in paying Thomson and Co. their debt of £100 De la Rue will have to pay for this trouble, the rate of exchange will be against him. If the debt, or any part of it, cannot be met by such an adjustment out of cross debts and credits, it will be necessary for the debtor to send bullion to his creditor; and, this being an expensive process, it throws the rate of exchange

against the debtor who so pays. For instance, if the sum due by the Frenchmen to Van Pradt was only £25 instead of £50, then De la Rue would have had to be at the expense of sending £25 to London in bullion.

No such actual transactions take place in the existing mercantile world, because the accounts in debtor and creditor connected with the three towns above referred to are to be counted in thousands, and ramify into other towns; but the above examples may be held to represent the groups of debtors and creditors, as algebraic signs represent quantities. The individual merchants in one trading town have no idea how the surplus of debit or credit may lie between them, far less can they tell how it may be adjusted by debits and credits in other towns; but, through the agency of bankers, bill-discounters, and other persons who deal in money, the relations of all trading-places towards each other are in a constant state of shifting and adjustment; and any one who has to pay a debt in any trading-place can find out how much he has to give to get that debt paid, and can pay it accordingly. When, through the operation of these complicated transactions, you require to give more than £100 in London to get that amount paid in Paris, then the rate of exchange is against London, and is in favour of Paris, where less than £100 in cash will pay a debt of £100 in London. The difference will generally depend on the difficulty of adjusting questions of debt and credit throughout the field of European commerce in such a manner as to get the debt paid. If it cannot be paid by adjustment, then bullion must be sent; and thus it is generally said that the rate of exchange against any place is limited by the charge of transmitting bullion to it. The rate of exchange is liable to be brought to a level also by commercial exportation and importation, since, whenever it is expensive to get money sent to a country, goods may be sent to that country to compensate the debt. In the general circle of transactions of this kind, the state or town which has the largest amount of transactions will have the largest number of debtors and of creditors, and will thus afford the chief facility for each compensating the other. For this and other reasons London is the centre of the money-market, where all the debts and credits in the world may be said to meet and extinguish each other (see BILL OF EXCHANGE). While the old notions about the Balance of Trade (q.v.) existed, it was supposed that the nation which the exchange was against was going to ruin, while that which it was in favour of was prospering through the other's loss. Such general statements must be tested by a comprehensive analysis of all the relevant facts. Gold-producing countries find bullion their most advantageous export, and the same is the case with countries into which gold has flowed in excess.

Exchange, a term applied to buildings or places of resort for merchants. The name *Bourse* (Lat. *bursa*, 'purse') is applied in France and Belgium to a resort of this kind; and in Germany, *Börse*.

Exchanges originated in the commercial cities of Italy, Germany, and the Netherlands; and Sir Thomas Gresham, who had resided as English agent at Antwerp in 1550, chose the Bourse of that city as a model for the Royal Exchange of London. Gresham's Bourse, for so it was originally called, was built on Cornhill in 1566-67. It consisted of a quadrangle with an arcade; above was a corridor (called the *gawn*) with stalls, for the sale of wares; outside were shops. On January 23, 1571, the Bourse was ceremoniously opened by Queen Elizabeth, who, by herald and trumpet,

caused it to be proclaimed 'The Royal Exchange.' This first exchange of London was almost entirely destroyed by the great fire of 1666. A new exchange was forthwith erected on the spot, and opened in 1669; but it also was destroyed by fire, in 1838. The foundation-stone of the third exchange was laid in 1842; and completed at a cost of £180,000, from the designs of Tite, it was opened October 28, 1844, by Queen Victoria.

The term exchange seems to have been naturally adopted from the circumstance that buying and exchanging of merchandise, and also exchanging and paying away of money, formed the chief object of concourse. In the present day, early intelligence in matters affecting commerce and public finance forms a principal attraction of this kind of resort. Although open daily, there are usually certain days and hours of meeting when the throng is considerable. The meeting is familiarly called 'Change.' The two great days of meeting at the Royal Exchange, London, are Tuesday and Friday, and the busiest time is from three to four o'clock.

In London there are several other exchanges, but for special purposes; among these are the Corn Exchange in Mark Lane, the Coal Exchange in Lower Thames Street, the Hop and Malt Exchange in Southwark, the Hide and Skin Exchange or Market in Bermondsey, and the Stock Exchange, near the Bank of England. Amongst the exchanges in the large towns of England and Scotland, those of Manchester, Liverpool, and Glasgow are specially noteworthy. There are exchanges, many of them for special purposes, in Augusta, Baltimore, Boston, Brooklyn, Buffalo, Charleston, Chicago, Detroit, Louisville, New Orleans, New York, Philadelphia, Richmond, St Louis, San Francisco, and other cities of the United States. See CHAMBER OF COMMERCE, STOCK-EXCHANGE.

Exchange, DEED OF, in English law, a common law assurance, whereby persons severally seized of lands mutually grant them in exchange, each his own land for that of the other. The two subjects must be of the same nature, as lands for lands, chattels for chattels, but not real for personal estate. The parties must take an equal estate—thus, an estate in fee cannot be exchanged for an estate tail; and the word 'exchange' must be used. There must also be entry, and if either party die before entry his heir may avoid the transaction. Exchange must now be made by deed, but this form of conveyance is seldom used, the same purpose being effected by two separate deeds of grant. A mutual warranty and right of entry was formerly implied in an exchange. This effect of the deed has been taken away by an Act of 1848. By the Common Enclosure Act of the same year the commissioners are empowered to make exchanges for the better carrying out of the purposes of the act. A deed of exchange closely resembles in its particulars an Excambion (q.v.) in Scotland. The law as to exchange in most of the American states is founded on and similar to that of England.

Exchanges, MILITARY, are certain arrangements made between officers of the British army to enable them to change their regiments or stations. Officers exchanging must be of the same rank. Artillery, engineer, marine, or departmental officers can only exchange in their respective corps, and do not lose seniority by doing so. Officers of other branches may exchange with each other, but, if they change regiments, go to the bottom of the list of officers of corresponding rank. Exchanges are ordinarily arranged by the Army Agents (q.v.), and others who make it their business to carry them out; but each exchange

requires the sanction of the Army Council, and of the two commanding officers affected by it. Considerable sums are often paid by one officer to another to induce him to exchange.

Exchequer. The ancient Exchequer in England was a branch of the King's Court, in which sheriffs and others were held to account for the revenues they received, and questions relating to the royal revenue were decided. The name exchequer (Fr. *eschequier* in the 12th century, from *eschec*, 'check' at chess) was derived from the checkered tablecloth on which money was counted, a practice which was continued in the Scottish Court of Exchequer down to modern times. In England the financial department of the court was called the receipt of the Exchequer. The Chancellor of the Exchequer was originally appointed as under-treasurer, to check the proceedings of the Lord High Treasurer (see TREASURY). He sat as a judge on the 'equity side' of the Court of Exchequer, or on the rehearing of cases in which the other judges of the court were equally divided in opinion. But in modern times his position has been that of first finance minister of the crown; the office is sometimes held by the prime-minister, when he is a member of the House of Commons. The last case in which the Chancellor of the Exchequer sat as a judge was in 1735; the decision then given by Sir Robert Walpole is said to have caused great satisfaction; but his successors have not figured among the judges except on occasions of state and ceremony. The receipt of public revenue now belongs to the several revenue departments, under the supervision of the Exchequer and Audit Department and the Treasury. See books by Madox (1711), J. H. Round, Hubert Hall, and R. L. Poole (1913). For exchequer tallies, see TALLY.

The Court of Exchequer was originally, as has been stated, a revenue court, but it obtained a general common-law jurisdiction by means of the writ of *Quominus*, wherein it was set forth that the plaintiff, by reason of the wrong done to him by the defendant, was deprived of the means of discharging his debt to the crown. This fiction was abolished in 1832. The ordinary judges of the court were the Chief Baron and three puisne Barons, so called, according to Selden, 'because they were anciently made of such as were barons of the kingdom.' The equity jurisdiction of the court is said by Coke to date from a statute of 1542; it was transferred to the Court of Chancery in 1842. In 1875 the Exchequer became a division of the High Court of Justice. The Exchequer Division is now merged in the King's Bench Division; the office of Chief Baron has been abolished, and no judges are now appointed with the title of Baron. See COMMON LAW, and Coke's *Fourth Institute*.

The Court of Exchequer Chamber was formerly a court of all the judges in England assembled for decision of matters of law. The ordinary jurisdiction of the Court of Exchequer Chamber was as a court of error, in which capacity it revised the judgments of the three courts of common law; the decisions of each court being revised by the judges of the other two. An appeal now lies from each division of the High Court of Justice to the Court of Appeal.

In Scotland, before the Union, the Exchequer was the king's revenue court. It consisted of the treasurer, the treasurer-depute, and as many of the lords of Exchequer as the king was pleased to appoint. The Scottish Court of Exchequer was continued by the 19th article of the treaty of union, until a new court should be established, which was effected in 1707. A privative jurisdiction was conferred on the court as to questions relating to revenues and customs of excise, and as

to all honours and estates real and personal, and forfeitures and penalties arising to the crown within Scotland. But questions of *title* to lands, honours, &c. were reserved to the Court of Session. The judges of the court were the high treasurer of Great Britain, the chief baron, and four other barons; and English barristers as well as Scotch advocates were allowed to practise in the court. In cases of difficulty, and where there was a collision of jurisdictions, it was formerly not unusual to hold conferences with the barons; and the form of desiring the conference was to send the Lord Advocate, and, in his absence, the Solicitor-general, to request a meeting, though it has been doubted whether they were bound to carry the message. In 1832 it was enacted that successors should not be appointed to such of the barons as should retire or die, and that the duties of the court should be discharged by a judge of the Court of Session. And in 1886 the Court of Exchequer was abolished, and the jurisdiction transferred entirely to the Court of Session.

The Court of *Exchequer Chamber* in Ireland was established in 1800, but was abolished as an intermediate Court of Appeal between the Irish Courts and the High Court in England.

Exchequer Bills, bills issued at the Exchequer under the authority of acts of parliament, as security for money advanced to the government. They contain an engagement on the part of the government for the payment of the principal sums advanced, with interest. These once formed the chief part of the unfunded debt of the country. They were first issued in the reign of William III., in the year 1696, and were drawn for various amounts from £100 to £5. At that time they bore interest at the rate of 3d. per day on £100. The interest was reduced to 2d. during the reign of Anne. During the war 1793-1814, the rate of interest was usually 3½d. Holders of these bills were exempt from all risk, except that arising from the amount of premium or discount they might have given for them. The bills passed from hand to hand as money, and were payable at the Treasury at par. They might also be paid to government in discharge for taxes. When it was intended to pay off outstanding Exchequer bills, public notice was given by advertisement. The advances of money to government by the Bank of England were made on Exchequer bills. These bills were a convenient means whereby government could meet a sudden demand for unusual expenditure. They went out of use in 1897. See NATIONAL DEBT.

Exchequer Bonds, issued by the government, are promises to pay a specified sum after a stated time, the rate of interest being fixed.

Excise, the name of a tax on commodities, from the Latin *excisus*, 'cut off,' as being a portion of the value of the commodity cut off and set apart for the revenue before the commodity is sold. This is not its actual nature, however, for the manufacturer who looks to a profit on his product does not give part of the value to the revenue; he merely counts the tax as part of his expenditure, or, in other words, includes it in the price, the tax being really paid by the consumer. An inland tax on commodities sold and bought for consumption in the country is a very ancient one, but it has generally appeared in the simple shape of a toll or *octroi* on goods brought to market. The complicated arrangement for officially watching the process of a manufacture, for the purpose of seeing that none of the dues of the revenue are evaded, is of comparatively modern origin. It was first introduced into England, upon the Dutch model, by the Long Parliament, which established an excise on liquors in 1643, and in subsequent years on articles of

food, salt, silk and stuffs, and other commodities in general use. Though unpopular, the excise in some form or other has ever since continued to be a material element in the taxation and revenue of Britain. In the earlier part of the 18th century Sir Robert Walpole entertained the notion of enlarging its productiveness, while mitigating its proportional pressure by the bonding system, which suspends the exaction of the duty until the goods are sold, and thus leaves the manufacturer with all his capital to be devoted to production (see **BONDED WAREHOUSES**). But the rumour of an enlargement of the unpopular excise duty created a general excitement, and the memorable cry of 'Liberty, Property, and No Excise,' compelled Walpole to abandon his project.

An excise, when compared with other taxes, has its good and its bad features. It is a method of extracting money for national purposes from personal expenditure on luxuries, and is especially serviceable when received from those luxuries the use of which in excess becomes a vice. On the other hand, it renders necessary a system of inquisitorial inspection not very agreeable to a free people, and open to abuse and fraud; while at the same time excessively high duties, and duties on commodities strictly of domestic manufacture, lead to smuggling and all its demoralising consequences. The evils of an excise were formerly aggravated by the practice of farming the duties—i.e. by letting them to the highest bidder, whose interest it became, like any other contractor, to make the greatest possible profit by his speculation, and consequently to exact the duties in the most rigorous manner. In every well-regulated revenue system it is, of course, only fair to all parties that the duty, as the law lays it on, should be fully exacted; but in the age of farming the arrangements were all slovenly, and there was much latitude of power in the hands of the farmers. The farming system became very oppressive in France, especially in the *gabelle* or excise on that necessary of life, salt. It is a curious fact, however, that when the farming of the excise was abolished in Scotland by the Union the people grumbled, saying they were easier under the farmers, their own neighbours, who acted on the principle of 'live and let live,' than under the officers sent down from England, who rigorously collected the impost.

An excise works most easily when it is laid on some commodity manufactured on a large scale. In a great distillery the excise officer is almost a portion of the establishment; he has an eye on every step of the process, with the object of seeing that the commodity does not get into the market without government obtaining its proper share—sometimes far the greater part—of the market price. The social influence of such an arrangement is very different from that of the old candle and salt duties, which made it the function of the exciseman to pounce on a farmer melting the surplus tallow of the last killed sheep, or on a fisherman boiling sea-water to procure salt for his potatoes. The manufacturer, however, though he has the benefit of the bonding system, feels the excise regulations to be a considerable drag and hindrance in his operations, since there are numerous minute operations which he cannot perform without sending special notice to the excise department, or having an officer actually present. This renders it necessary, too, that all the steps of the process should not merely be defined as between the manufacturer and the officer, but should be set forth in an act of parliament; and hence deviations for the purpose of economy, or by way of experiment, become difficult, and sometimes impracticable. As difficulties with which the pro-

ducer has to contend, these things require him to lay on the selling price of the commodity a larger addition than the actual amount of the duty. This objection, however, is less potent than it formerly was, for the introduction of machines and special apparatus, such as alcoholometers, saccharometers, &c., has greatly facilitated the collection of excise duties.

No method of taxation requires a nicer adjustment to the social condition of a country than an excise. While it is now admitted that necessities of life should be free, yet some form of tax upon consumption is the only method by which certain classes of the people can be made to contribute their share to the revenue of the country. But for the excise and customs dues on beer, spirits, and tobacco, and some licenses, many persons would evade all share in the national burden.

Excitants. See **STIMULANTS**.

Exclusion Bill, a measure brought forward by Shaftesbury in 1679 to exclude the Duke of York, afterwards James II., from the succession to the throne, on account of his avowed Catholicism. It thrice passed the Commons, and as often Charles II. resorted to a dissolution, till, after March 1681, he ruled without parliamentary control.

Excommunication. The word 'excommunication' denotes exclusion, whether temporary or permanent, from fellowship in religious rites, involving also, where participation in such rites is required in the civil order, privation of the rights of citizenship. It is not peculiar to the biblical religions, but is found in most of the systematised cults, whatever be their origin. Thus, Cæsar describes its operation amongst the Gauls, stating that contempt of the decisions of their judges was visited with interdiction from the sacrifices. 'This is a most severe penalty with them. For those so interdicted are counted as sinful and wicked; all keep aloof from them, and avoid approaching or addressing them, lest they should incur some injury by contact; they are granted no right which they claim, nor is any honour bestowed upon them' (*Bell. Gall.* vi. 13). The absence of any remark as to a corresponding usage amongst the Romans and Greeks of the time is enough to show that Cæsar was not familiar with the practice; but slight indications are discoverable of analogous usages, so far as regards exclusion from common acts of worship, amongst which the Latin word *profanus*—signifying that which is 'outside the temple'—may be specially cited. The clearest analogy, however, to the Christian discipline of excommunication is that furnished by the Rabbinical code. This is ultimately based on the legislation of the Pentateuch, which excluded the ceremonially unclean, as well as offenders of a graver kind, both from religious and civil fellowship (*Lev.* xiii. 46; *Numb.* v. 2, 3; xii. 14, 15); and the penalty is recorded in *Ezra*, x. 8, as enforced against such Jews of the captivity as disobeyed the proclamation to assemble at Jerusalem. The offender first received a public admonition, and seven days later, if he did not make satisfaction, the lesser excommunication, *Niddui*, was pronounced against him, whereby he was isolated during thirty days from contact with all save his wife and children, being obliged to keep at least 4 cubits' distance from all others; and although the sentence did not technically include expulsion from the synagogue, yet this provision practically enforced it. At the expiration of the 30 days, a second term of like duration was enjoined in case of continued impentence; and the contumacious were then visited with the greater excommunication of *Cherem*, which excluded both from the synagogue and from all social inter-

course, and the offender was treated as a leper. These two grades of excommunication were the only ones anciently in use; but the later Rabbins added a third and severer one, styled *Shammatha* or *Anathema Maranatha*, which was lifelong, attended with solemn imprecations, and sometimes entailing forfeiture of goods.

The Christian system of excommunication is based doctrinally on the precept of Christ (Matt. xviii. 15-18) and on the precepts and practice of St Paul (Rom. xvi. 17; 1 Cor. v. 3-5, 11; 2 Thess. iii. 14) and St John (2 John, 10, 11); while its practical method was borrowed from the synagogue, and formulated certainly by the 3d century, perhaps as early as the 2d. It was primarily, as the word denotes, exclusion from communion in the eucharist and the *agape* or love-feast, including also suspension from office in the case of clerical offenders; and it was distinguished as major and minor, each having various degrees of severity. Thus, the lightest form of excommunication permitted the offender to join in all acts of public worship except to make oblations and actual reception of the eucharist; the grade next below was not suffered to be present during the latter part of the liturgy, but only during the preliminary prayers and the remaining public offices; below this class again came those who were excluded entirely from the prayers, but permitted to enter church to hear the Scriptures read and sermons preached; while the lowest grade of all was refused permission to enter church, being obliged to remain outside the doors until the expiry of their term of penance. Similarly, the major excommunication, besides its exclusion of offenders as well from social intercourse as from all participation in church fellowship and ordinances, which applied in all cases, had also the graver form of anathema, fulminated against the most obstinate offenders, and chiefly such as taught or abetted heresy, or, at a somewhat earlier date, those who had lapsed in time of persecution, and had either sacrificed to idols or obtained certificates alleging them to have done so. The controversy as to the possibility of readmitting such persons to communion at all—denied by the Novatianist or rigorist school—was one of the most serious which agitated the church in the 3d century; and, though the milder course ultimately prevailed, yet even the moderate party insisted upon very severe and prolonged penalties, seldom pardoning the offender till the very close of life, unless at the personal intercession of a martyr. Notice of such greater excommunication was sent by circular to all churches in the case of clerical offenders or laics in official positions, to insure the universal incidence of the penalty; and intercourse with any one underlying it involved the same punishment as the original offence, the lesser excommunication being incurred *ipso facto*, and the greater by persistence in such intercourse after admonition. At a very early date the aid of the civil power was invoked in support of the spiritual sentence, not only by preventing resistance thereto, but by superadding a temporal penalty. Thus, the fifth canon of the Council of Antioch in 341, after enacting that any cleric setting up a schismatical place of worship shall be deposed for life, adds: 'And if he persist in troubling and disturbing the church, let him be corrected by the civil power as a seditious person.' And in the third Council of Carthage in 397 a canon (xxxviii.) was passed to petition the governor of the province to remove an intruding bishop who had disregarded the ecclesiastical censures passed upon him; which was embodied later in the general code of the African church, as well as two others of a like nature (lxvii. and xciii.) directed against the Donatists. In the Theodosian Code

there is a law imposing a fine of ten pounds of gold upon all heretical persons conferring or receiving ordination, further confiscating the place where the act occurred, if done with the knowledge and assent of the owner; and many such enactments appear in later history, such as the decree of Childebert in 596, the Capitularies of Pepin in 755, and the Constitutions of Lothar I. in 825, whereby excommunicated persons were put to the ban of the empire; while a constitution of Frederick II. in 1220, alleging that the material sword is appointed for the aid of the spiritual sword, enacts that, in the event of excommunicated persons not making satisfaction within six weeks from the sentence, the civil ban is to issue thereupon, and not to be revoked until the previous removal of the excommunication. The theory that the spiritual sword might be turned against the civil power itself, and that excommunication deprived sovereigns and other magistrates of their authority, voiding, indeed, all civil rights, is peculiar to Latin Christianity, and is a development of the Hildebrandine era and policy (see ALLEGIANCE), first put into actual execution by Gregory VII. against the Emperor Henry IV. in 1076, and again in 1080, renewed in 1084 by Urban II., and in 1102 by Paschal II.; and later against the Emperor Philip of Swabia, and in favour of his competitor Otho IV. by Innocent III. in 1210. It is commendously stated thus by Cardinal Francis de Toledo (1532-96) in his *Instructio Sacerdotum*, a work of much repute, recommended by Bossuet: 'An excommunicated person cannot exercise an act of jurisdiction without sin; nay, if the excommunication be publicly made, his sentences are null' (lib. i. cap. 3). Instances of the kind are the excommunication of Napoleon I. by Pius VII. in 1809, and that of Victor Emmanuel II. by Pius IX. in 1870. But the omission of their names in these documents, which are vaguely and indefinitely fulminated against enemies and oppressors of the holy see, barred the full operation of the sentences in canon law, and left the question of allegiance untouched.

In the actually current discipline of the Roman Catholic Church a distinction is drawn between such sentences of excommunication as are incurred *ipso facto* (technically known as *latae sententiae*) and such as do not take effect till after the formal sentence of an ecclesiastical court (called *ferendae sententiae*); and those subject to such sentences are distinguished as *tolerati* and *non-tolerati*, the former of whom are still eligible for social and civil intercourse, while the latter are absolutely excluded from all such communion, as well as from the ordinances of religion. In theory the right to pronounce the greater excommunication is limited to the pope solely, as also the power to absolve therefrom; but in practice this authority is conveyed to all bishops in their quinquennial faculties, for local exercise within their dioceses, and by them to the clergy under their jurisdiction, so far as regards absolution, but not for pronouncing sentence, which is never committed to any one below the rank of bishop or judge. In most Roman Catholic countries, if excommunication involves any civil disabilities, it cannot be published without the sanction of the civil power, and in some of them there is an appeal to the law-courts on the merits, to obtain fresh examination of the case at the hands of the ecclesiastical authorities. It is a mistake to ascribe to Roman Catholics the doctrine 'that excommunication may be pronounced against the dead.' The contrary is expressly laid down by all canonists (Liguori, *Theologia Moralis*, lib. vii. n. 13, 1). In the cases in which this is said to have been done, the supposed 'excommunication of the dead' was merely a declaration that the deceased

individual had, *while living*, been guilty of some crime to which *excommunication is attached by the church laws*. Roman Catholic writers, moreover, explain that the civil effects of excommunication in the medieval period—such as incapacity to exercise political rights, and even forfeiture of the allegiance of subjects—were annexed thereto by the civil law itself, or at least by a common international understanding in that age. Examples are alleged in the law of Spain, as laid down in the Sixth Council of Toledo, a mixed civil and ecclesiastical congress (638); in the law of France, as admitted by Charles the Bald (859); in the Saxon and in the Swabian codes; and even in the English laws of Edward the Confessor; all which, and many similar laws, proceed on the great general principle of these medieval monarchies—viz. that orthodoxy and communion with the holy see were a necessary condition of the tenure of supreme civil power; just as by 1 Will. and Mary, sect. 2, chap. 2, profession of Protestantism is made the condition of succession to the throne of England. Hence, it is argued, the medieval popes, in excommunicating sovereigns, and declaring their subjects released from allegiance, did but declare what was, by the public law of the period, the *civil* effect of the exercise of what in them was a *spiritual* authority.

By the discipline of the Roman Catholic Church, kings or queens, and their children, are not included in any general sentence of excommunication, unless they be specially named.

Certain 'reserved cases' are limited to the pope alone, and are enumerated in the brief 'Apostolicæ Sedis,' promulgated by Pius IX. in 1869, which also contains a list of those sentences, *læte sententiæ*, now in force within the Roman Church; but an ordinary priest is permitted to absolve those at the point of death from even the reserved excommunication.

The oriental discipline is much less elaborate, and more nearly accords with ancient practice; but the distinction between the greater and lesser excommunication is retained, and no fewer than 115 offences, involving various degrees of excommunication, are specified in the office-books, ranging from twenty years' exclusion, for such crimes as murder or magical practices, down to bigamy, with its penalty of one year and merely ceremonial disqualifications, yet briefer in effect. The greater anathema is fulminated yearly throughout the Eastern Church on Orthodox Sunday (first Sunday in Lent) against about sixty forms of heresy, for the most part extinct; but in the Russian Church they have been cut down to twelve still prevalent types of opinion.

In the Church of England the medieval practice conformed in the main to the current western usage, save in this one important respect, that an excommunication *ipso facto* was not really in operation; for though the term occurs frequently, yet what it denotes is only that, given a certain offence, excommunication must follow as the penalty, but a declaratory sentence of a competent court must precede the actual excommunication.

Various civil disabilities attended excommunication, and were continued after the Reformation, such as inability to hold a benefice, to practise as an advocate or attorney in the courts, to be admitted as a witness, and to receive Christian burial. By a canon of 1597 the ordinaries were to provide for the public denunciation monthly in the cathedral of the diocese and the parish church of the offender, in all cases where an excommunicated person had not made satisfaction and obtained absolution within three months after incurring sentence; and this was embodied in the canons of 1604 (lxv.), with the alteration to a half-yearly

denunciation, but with the further provision that those present should be induced to apply for a writ *De excommunicato capiendo*, 'thereby to reduce them to due order and obedience.' This writ was issued by the Court of Chancery on the application of the diocesan, and addressed to the sheriff or other officer, and warranted the imprisonment of those arrested under it. The disabilities attending excommunication were abolished for England by the Act 53 Geo. III. chap. 127, and for Ireland by the 54 Geo. III. chap. 68; while all remaining penalties against persons dissenting from the worship and doctrines of the Church of England were repealed by 7 and 8 Vict. chap. 2, and 9 and 10 Vict. chap. 59. The most notable exercise of the power of excommunication in the modern Anglican Church was when Bishop Gray, as Metropolitan of Capetown, deprived and excommunicated Bishop Colenso of Natal in 1863, which sentence, approved by the Convocations of Canterbury and York, the General Convention of the American Episcopal Church, the Episcopal Synod of Scotland, and the Provincial Council of Canada (as well as by a large majority of the bishops assembled at the first Lambeth Conference in 1867), was reversed by the Judicial Committee of Privy-council in 1865, on the ground that the crown had no power to erect the see of Capetown into a metropole, nor to give Bishop Gray the coercive jurisdiction on which he had relied as empowering him to try one of his suffragans and pass sentence upon him.

In the Established and other Presbyterian churches of Scotland, the lesser excommunication, involving deprivation of all 'sealing ordinances,' can be pronounced by the kirk-session. The greater excommunication can be pronounced by authority of the presbytery only; it is now very rarely heard of, and since 1690 it does not carry with it any civil consequences.

A very singular kind of excommunication is that connected with the usage of *tabu* amongst the islanders of Polynesia. *Tabu* is a species of interdict which may apply to persons or things; in the latter case making any use of the interdicted article, or even contact with it, unlawful and penal; in the former cutting off the interdicted person from all intercourse or contact with others, and even prohibiting him to use his hands to feed himself; a chief or noble being allowed a servant, also put under *tabu*, to feed him, and a man of lower rank being obliged to pick up his food with his mouth only, like a beast.

Islam forms an exception to the almost universal incidence of the practice of excommunication. Under the Moslem code every religious offence carries with it a temporal penalty, such as fines, scourging, stoning or other mode of death, and only in this last manner can an offender be cut off from the congregation. See BELL (for 'Bell, book, and candle'); also INTERDICT.

Excretion. See SECRETION; and for the excretory organs, see RESPIRATION, SKIN, KIDNEY, URINE, &c.

Exe, a river of Somerset and Devon, rising in Exmoor, and flowing 54 miles south-eastward and southward to the English Channel at Exmouth. The lower 5 miles form a tideway a mile broad at high-water, with wooded and picturesque shores, and navigable for large vessels. An ancient canal connects the estuary with Exeter (q.v.). The chief tributaries of the Exe are the Barle, which also rises in Exmoor, and is 24 miles long, Batlam, Loman, Culm, and Creedy. The Exe passes Dulverton, Bampton, Exeter, and Topsham. The greater part of its course is through wooded and romantic vales.

Execution, in Law, is the act of completion

or carrying into effect. Thus a writ is executed by obeying the instructions contained in it; a Deed (q.v.) is executed when it is signed, sealed, and delivered; a power is executed when it is exercised; a judgment of a court is executed when it is enforced. Judgments are usually enforced by writs of execution, which direct the officers of the law to do what is necessary, or to compel a defendant to perform some act. The term 'execution' is used now technically to denote execution to recover a debt—the kind that occurs most usually in practice. In Scotland, the term execution is also applied to the written attestation under the hand of the executive officer that he has carried his warrant into effect, as by serving a summons or giving a citation. It corresponds to the affidavit of service of writ in England.

Execution, in civil law. In civil cases the common law of England allows four different writs to issue against refractory debtors—viz. a *fi. facias* (called commonly a *fi. fa.*), a *capias ad satisfaciendum* (*ca. sa.*), *levari facias*, and *elegit*. These writs issue from the court of the Division in which the proceedings are grounded, and are addressed to the sheriff of the county. By a *fi. fa.* the goods and chattels of a debtor may be attached. This writ lies against all proprietors, peers, &c., and is by far the commonest form of execution. A writ of *ca. sa.* is directed against the person of a debtor, and authorises his detention until the debt has been satisfied. But though probably still competent in certain cases, it has been in practice obsolete since the abolition of imprisonment for debt; and practically the only forms of execution against the person now in use are writs of attachment and committal. These are both founded on contempt, and are very similar. The terms are, indeed, used loosely as interchangeable, and the distinction between them is narrow and technical, lying merely in the service necessary and the officer charged with execution. A *levari facias* is now seldom used. It is directed against a man's goods and the profits of his lands. The writ of *elegit* is of very ancient date (see *ELEGIT*). In the Chancery Division of Court, execution against the estate is effected by writ of *fi. facias* or writ of *elegit*. Execution against the person is by writ of attachment. Should this latter writ be returned *non est inventus*, the party prosecuting has it in his option to take out a writ of sequestration of the estate, with issues of course, or to obtain an order for the serjeant-at-arms. An attachment does not lie against a peer or other privileged person, but an order called a sequestration *nisi* is issued. In cases of contempt, the High Court in each division has also the power to order personal commitment. In all cases execution may issue immediately, each writ being renewable after a year, within six years; but the court or judge can stay execution to a time fixed—or subject to conditions.

In the United States, the law of execution is complicated by the rules which define the local jurisdiction of district and state courts and of the United States courts. The writs of execution in use are *fi. facias*, *levari facias*, &c.; the writ of *elegit* is now little used. In some states the homestead and other property of a debtor are exempted from execution; and congress has enacted that execution issuing out of United States courts must follow the provisions of these local laws.

In Scotland, execution for debt, or, as it is technically expressed, diligence in execution, is either real or personal; by the former, the debtor's lands may be attached; by the latter, his person or his movables. In order to entitle a creditor to use diligence against the person or estate of his debtor, the debt on which the diligence proceeds must be

duly constituted by a liquid document, or by a decree, or by an action in which decree is sought. In this last case, the law, as a rule, allows diligence on the dependence of the action, in order that a party may not be deprived of his remedy during the currency of the action, but such diligence depends for its effect upon the judgment in the cause. In the case of bonds and other instruments registered for execution (see *REGISTRATION*), the law allows summary diligence to proceed; that is to say, execution may proceed without the need of further application to the court. Diligence against heritage includes Inhibition, which is a writ passing under the signet, and prohibiting the debtor from contracting any debt which may become a burden on his heritage to the prejudice of the inhibitor's debt; Adjudication (q.v.); Ranking and Sale, a process of law by which the heritable property of an insolvent is judicially sold, and the proceeds divided among his creditors; and Pounding of the Ground, which is an action proceeding on a heritable security, and attaching all the goods on the lands over which the security extends. Personal diligence is (1) by Horning and Caption, where letters of horning—i.e. letters running in the sovereign's name, and passing the signet—are issued instructing messengers-at-arms to charge the debtor to pay, and on his failure a caption or warrant for his apprehension is granted; (2) by the simpler form of Warrant to Charge under the Personal Diligence Act, which replaces the old process of horning and caption; (3) by Arrestment (q.v.); (4) by Pounding; (5) by Mercantile Sequestration.

Execution, in criminal law, is the infliction on criminals of the punishment of death in conformity with legal decree (see *CAPITAL PUNISHMENT*). The modes of execution have varied greatly, both in the progress of time and in different countries. On the whole, the manner of executing the death-penalty, as of decreeing and inflicting punishment in general, has tended to grow more humane with the advance of civilisation. Among the Jews a frequent form of execution was stoning, while burning alive appears (Genesis, xxxviii. 24) to have been practised in their patriarchal history, and is sanctioned by Mosaic law. Casting from a rock was a mode recognised by the Jews and the Twelve Tables of the Romans. Under the Roman republic vestal virgins violating their vows of chastity were buried alive, and in the time of Paul crucifixion, burning, and decapitation were the chief modes of execution. Crucifixion (see *CROSS*) was in use likewise among the Assyrians, Persians, Egyptians, Carthaginians, and Greeks. Constantine, on his adoption of Christianity, abolished crucifixion in the Roman empire. The Italians of the middle ages, however, crucified some of their prisoners of war. Another revolting form of execution among the Romans was that of condemning the criminal to fight with wild beasts. Impalement, by thrusting a sharp stake through the body lengthwise, was one of Nero's cruelties, and is referred to by Juvenal. It is said to have been practised in the Balkan Peninsula so recently as 1876. Under Charles V. impalement was effected by driving a pointed stake through the heart while the criminal in open grave was being covered with earth. Other barbarous modes of execution were pouring melted lead on the criminal; sawing him asunder, a mode practised by the Jews against the conquered in Palestine; starvation in dungeons; pressing to death; breaking on the wheel; tearing to death with red-hot pincers. Boiling alive was occasionally practised on the Continent; and in England in Henry VIII.'s time poisoning was punishable by boiling to death, and 'it seems,' says Sir James Stephen, 'that three or four persons

were so boiled.' In 1532 sentence of boiling alive was put in execution against a miscreant who attempted to poison Fisher, Bishop of Rochester, and actually poisoned some of his household. The act under which that sentence was carried out was repealed by 1 Edward VI. Drowning a paricide in a sack, in which were also a dog, cock, viper, and ape, was a Roman punishment, imitated in the middle ages, when quartering alive, tearing to pieces by horses, and disembowelling were likewise punishments known on the Continent. Among the severer forms of military execution were hunting and spearing the condemned to death by his fellow-soldiers, practised in Germany in the time of the Lantzknecchts of the end of the 15th and during the 16th century; making him run the gantlet of rods till dead; flogging him to death with the knout. These last two modes of execution were practised in Russia till into the 19th century.

English law has in practice, according to Sir J. Stephen, been in a marked manner distinguished from the practice of the Continent by its aversion to execution by torture. The usual mode of execution in England has been for many centuries, and still is, hanging, though in early times decapitation was also known. Treason, however, was punished in the case of men by hanging, drawing (anciently dragging at the tail of a horse), and quartering; of women by burning. A woman was burned alive for petty treason (killing her husband) at Tyburn in 1726. Heresy was also punished by burning. In 1283 David, the last native Prince of Wales, was for treason sentenced to be hanged, drawn, and quartered, and to have his bowels burned. Pressing to death, or the *peine forte et dure*, is said to have been practised as late as 1741 at the Cambridge assizes. Burning continued till 1790 to be the punishment inflicted on women for treason, high or petty; at Ipswich a woman was burned in 1783 for murdering her husband. In practice, however, women were strangled before being burned. A woman was burned for witchcraft at Dornoch in Sutherland in 1722. By 25 Geo. II. any person convicted of murder was to be executed on the next day but one after sentence, but if sentenced on a Friday he was to be hanged the following Monday. In the interval he was to be fed on bread and water, and his body after death was to be either dissected or hung in chains. By laws passed in 1832-34 the bodies of murderers were no longer to be anatomised or hung in chains, but to be buried in the precincts of the prison in which they were last confined before execution. This regulation, repeated in 24 and 25 Vict., is now in force. On 21st February 1803 Edward M. Despard (q.v.) was drawn on a hurdle, hanged, and decapitated; and on 1st May 1820 Thistlewood and four of his fellow-conspirators were likewise hanged and decapitated. In this case—the last decapitation for treason in England—the head was cut off with an amputating knife by a masked executioner, who then thrice held it up by the hair to three different points of the compass, with the words, 'This is the head of Arthur Thistlewood, a traitor.' The mode of execution now obtaining in Britain and British colonies is hanging; in Austria, strangling; in Spain, Garroting (q.v.); in France, decapitation by the guillotine; in Germany, decapitation. In New York state it was enacted that after 1st January 1889 executions should be by electricity, a mode calculated to effect instantaneous death; some other states of the union have followed. Lynching (see LYNCH LAW) sometimes takes the place of judicial execution in America. The Bowstring (q.v.) was an old Turkish institution; and the Hara-Kiri (q.v.) was peculiar to old Japan.

Shooting is the military form of execution. In India, during and after the mutiny of 1857-58, some of the rebels were blown from the mounds of cannon. Till 1868 executions in the United Kingdom were performed publicly, in London for the most part at Tyburn till 1783. At Edinburgh the place of execution was chiefly in the Grassmarket till 1784, when it was transferred to a platform at the west end of the Tolbooth, a building removed in 1817. The gallows at Tyburn was a permanent erection on three posts, 'Tyburn's triple tree,' and wooden galleries near it accommodated the crowds of spectators. The scandalous scenes, however, attending the procession of the criminal from Newgate to Tyburn caused the place of execution to be changed in 1783 to the area in front of Newgate prison, where on the 31 December 1783 ten were executed.

In 1868 an act was passed prohibiting public execution, and directing that all executions proceed inside the walls of the prison in presence of the sheriff, gaoler, chaplain, and surgeon of the prison, and such other officers of the prison as the sheriff requires or allows. The Act of 1868 further orders that execution take place at 8 A.M. on the first Monday after the intervention of three Sundays from the day on which sentence is passed. A black flag has to be hoisted at the moment of execution conspicuously above the prison, and remain displayed for an hour, while the bell of the prison or parish church tolls for fifteen minutes before and fifteen minutes after the execution. Till 1783 the mode of execution was by drawing away the cart from under the prisoner after the rope had been fastened round his neck. From 1783 the prisoner was placed not on a cart but on a platform, which on the withdrawal of a bolt suddenly fell from under him. In 1874 this method was improved upon by a plan whereby the length of the rope is proportioned to the weight of the body, so that the momentum of the fall suffices to rupture the ligatures of the spine, and thus cause instant death. Execution in England must in all cases be performed by the sheriff, or, as is invariably the practice, by his deputy called the executioner. In royal burghs in Scotland, the office is imposed on the civic magistracy, one of whom attends the execution, similarly as does the sheriff in England.

In several German states the office of headsman is said to have been hereditary, and in *Coriolanus* (act ii. scene 1) Menenius speaks of 'hereditary hangmen.' The last headsman of the Tower of London died in 1861. The office had grown to be a mere sinecure. In some parts of England the office was annexed to other posts; for instance, in the time of Henry II. and Henry III. the porter of the city of Canterbury was executioner for the county of Kent, and in receipt on account of that office of an allowance of 20 shillings per annum from the sheriff. Derrick was public executioner in the first part of the 17th century, and gave his name to a kind of crane; after him came Gregory Brandon, whose son, Richard Brandon, executed Strafford, Laud, and Charles I. John Ketch, public hangman from 1663 till 1686, executed William Lord Russell and the Duke of Monmouth, and bequeathed his name ('Jack Ketch') as a nickname to his successors in office for nearly two centuries. The family of Sanson for many generations gave Paris her executioners, the name 'M. de Paris' being first playfully given to the elegant and handsome Charles Henri Sanson, who in his old age executed Louis XVI. In recent times, Calcraft, employed as executioner down till 1874, was paid by the corporation of London £1, 1s. per week as a retaining fee, and an extra £1, 1s. for each execution. He had, besides, from the county of Surrey £5, 5s. annual retaining fee, and £1, 1s.

for each execution, and £10 for an execution in the country. Calcraft was succeeded in 1874 by Marwood, who, in turn, in 1883, was succeeded by Berry; and he, before his resignation in 1892, had been engaged for over 200 executions, and carried 134 sentences into effect.

Execution of Deed. See DEED.

Executive. See GOVERNMENT.

Executor, in England, the person to whom the execution of a last will and testament of personal estate is by testamentary appointment confided. The appointing by will of an executor, without giving any legacy or appointing anything to be done by him, is sufficient to make a will. The appointment of an executor can only be by a will, the person who takes charge of the estate of an intestate being called an Administrator (q.v.). The appointment may be either express or constructive—i.e. gathered from the general terms of the will. An early duty of an executor is to take Probate (q.v.) of the will. He derives his title solely from the will; the estate vests in him from the death of the testator, at which time his responsibility begins, and from which time he may enter upon all the duties of managing the estate. But his position will not be recognised as suitor in any court until he has taken probate. The whole personal estate vests in the executor, and, if the testator has made no disposition of the residue, it devolves, as trustee for the next of kin, upon the executor, unless it appears from the will or any codicil thereto that the executor was intended to take the residue beneficially. By 21 Henry VIII. chap. 5, an executor is bound to prepare an inventory of the personal estate. This, if required, must be produced. An executor may raise actions in respect to the estate in his charge; and generally it may be said that his powers, duties, and liabilities are commensurate with those of the deceased, except in regard to contracts and wrongs of a merely personal nature. He may enter the house of the deceased to remove the personal property. The first claims to be discharged are those of the funeral and the expenses of probate. He must then pay the debts; and he is responsible for paying them in due order, so that those having a legal preference shall first be discharged. An executor is not bound to accept the office; but, if he administers, he cannot then renounce the executorship without cause. On the death of an executor, the office passes, as a general rule, to his executor. See Sir E. V. Williams's *Law of Executors and Administrators* (10th ed. 2 vols. 1905), or the shorter treatise of Walker and Elgood (4th ed. 1905).

In Scotland the term executor is given to all who manage the estate of a deceased, whether appointed by will, and administering the estate on behalf of the creditors and beneficiaries, or appointed to an intestate by authority of the court, and administering for the next of kin. The former are called executors nominate; the latter, executors dative. All executors must, before they can ingather the estate, obtain *confirmation* from the Commissary

Court. This is analogous to probate in England. But in Scotland no right vests in the executor until after confirmation, except a title to sue, being exactly the reverse of the English rule. An executor acting without confirmation is called a *Vitiosus Intromitter* (see INTROMISSION). Executors must, on applying for confirmation, exhibit a full inventory of the whole movable estate of the deceased. An executor is only liable to the extent of the inventory. He is not bound to pay interest on the funds in his hands unless they bore interest before confirmation, or unless he is guilty of undue delay in administering the estate. He is not bound to pay the debts for six months after the death of the deceased. But, as in England, the expenses of the funeral and confirmation are entitled to immediate payment. Servants' wages and a year's house-rent have also a preferable claim. By the Intestate Moveable Succession Act, 1855, an executor's claim to one-third of the *Dead's Part* (q.v.), after deducting debts, was abolished, and he now receives no benefit *qua* executor from the estate.

In the United States, the rights and duties of an executor are analogous to those defined by English law; in this, as in other matters relating to property, each State has its own laws. See Stimson, *American Statute Law*; Schouler, *Treatise on Law of Executors and Administrators* (Boston); *Cyclopedia of Law*, vol. xviii. (New York, 1905).

Executory, in English law, is opposed to 'executed,' and implies that something remains to be done. In an executory contract each party has some obligation to fulfil. An executory limitation of property is one which gives an interest to come into existence at a future time or on the happening of an event. An executory trust directs trustees to make a future conveyance in favour of the person beneficially entitled. Executory devises and other limitations form an important branch of the law of real property. In American law, the term executory is used as in England; executory gifts of property are subject to rules against Perpetuities (q.v.), similar to the rules which prevail in England.

Exegesis. The word comes from the Greek, and signifies 'interpretation' or 'explanation.' It may be applied to the interpretation of any book. Technically we may speak of any annotated edition of Sophocles, or Shakespeare, or Dante as exegesis, but, as a matter of fact, in common usage the word is generally restricted to the interpretation of the Bible. In former times scholars used to distinguish exegesis from hermeneutics. Hermeneutics was the science which investigated the principles of interpretation, exegesis the art which applied those principles to the explanation of any particular book or passage of Scripture. This distinction, however, has fallen into disuse, and the word 'exegesis' is now applied to both the science and the art of interpreting Scripture.

The principles of exegesis have varied, as the view with regard to the nature and character of Scripture has changed and developed. Three notable types of exegesis have come into prominence at different times: (a) the Allegorical, (b) the Dogmatic, (c) the Historical.

In the early centuries the allegorical method generally prevailed. It is a mistake, however, to suppose that the allegorical method was confined to the interpretation of Scripture. Hatch has shown in his Hibbert Lecture that this method was applied to the interpretation of Homer in the schools of Alexandria. A distinguished teacher found in Homer's phrase about 'the ceaseless flow of the ocean' an allusion to a prophecy of the Heraclitean principle, 'All things are in a state of flux' (*πάντα πρὶ*). The current doctrine of inspira-

tion which we find developed in Plato's *Ion* and the writings of Philo lent itself to the allegorical method. The words of Plato are most significant, 'The poet is a light and winged and airy thing, and there is no invention in him until he has been inspired and is out of his senses, and the mind is no longer in him. . . . God takes away the minds of the poets and uses them as his instruments, just as he uses divine and holy prophets, in order that we who hear them may know that they speak not of themselves when they utter these priceless words in a state of unconsciousness, but that God is the speaker, and through them he is conversing with us.' This theory of inspiration implied that all writings composed under its influence contained a full and complete divine revelation; if, therefore, the statements of these inspired works of antiquity seemed to exhibit inadequate knowledge, or to be in conflict with later discoveries, the defect could not be inherent in the book itself (seeing that it was inspired), but must be due to faulty interpretation. What was not on the surface must be looked for under the surface, and if it was not obvious even then, the plain meaning of the text must be twisted and distorted until it yielded the desired result. The category of historical evolution was almost entirely absent from the ancient mind, especially when a divine revelation was in question. Just as the Alexandrians could not conceive of the possibility that Homer was less learned than Heracitus, so the primitive Christian Church found it impossible to regard the Old Testament as representing a lower level of revelation than the New Testament. The fundamental position from which the Church started was that the Old Testament, being an inspired book, must contain the complete sum of divine truth. The aim of exegesis, therefore, was to discover the whole of the New Testament in the Old, and the most successful exegetes were those who could make the statements of the prophets and the psalmists yield the theology of St Paul. Two extreme illustrations may be given of the application of the allegorical method. Clement of Rome, for instance, makes the scarlet thread, which Rahab hung out of the window to direct the spies, 'show that a redemption must be made by the blood of the Lord for all who believe and hope upon God.' The epistle of Barnabas regards the 318 servants of Abraham as symbolic of the death of Christ upon the Cross, because the number is represented in Greek letters by I H T. I H stands for Jesus, T represents the Cross. It was the Alexandrian Church Fathers who carried the allegorical method to its highest point, and attempted to put it on a scientific basis. Origen laid down the principle that each separate text possesses three meanings—one for the body (the literal meaning), one for the soul (the ethical meaning), and one for the spirit (the spiritual meaning)—and of these three the literal sense of the passage was always the least important. The method of Origen was developed by later writers. In medieval times it became a recognised principle of exegesis that each statement in Scripture had four senses: (a) the literal or historical; (b) the spiritual or mystic, teaching what ought to be believed; (c) the moral or tropological, teaching what the course of conduct ought to be; (d) the anagogical, expressing the Christian hope. These four meanings were expressed in the well-known lines:

Littera gesta docet;
Quid credas, allegoria;
Moralis, quid agas;
Quo tendas, anagogia.

The Reformation changed the spirit of exegesis and substituted the *dogmatic* method for the allegorical. Luther was most vigorous in his protests against the vice of allegorism. 'When I was a

monk,' he writes, 'I allegorised everything; but now I have given up allegorising, and my first and best art is to explain the Scriptures according to the simple sense: for it is in the literal sense that power, doctrine, and art reside.' The principle of the dogmatic method is this: The interpreter approaches the Bible with a rule of faith which is the norm or standard of his exegesis. The assumption is that this standard faith will be found everywhere in the pages of Scripture, and each particular passage must be interpreted in the light of the tenor of the general teaching of the whole. Roman Catholic theologians applied the principle of the dogmatic method in one way, Protestants in another, but it was essentially the same method in both cases. The fundamental position of Roman Catholicism was that the Bible must be interpreted in relation to the authoritative decisions of the Church and the traditional exegesis of the Fathers. In other words, the text of Scripture is subordinated to the dogmatic decrees of the Vatican, and the private judgment of the modern interpreter must be in subjection to the patristic and scholastic interpretation of the Bible. The authority of the Church comes first, and Scripture, by an unscientific method of exegesis, is forced to support that authority. Undoubtedly Protestantism made a remarkable advance in some directions. Theoretically, at any rate, it subordinated the authority of the Church to the authority of Scripture. It boldly asserted the right of the modern interpreter of the Bible to depart from traditional patristic exegesis. It insisted upon the use of the original Hebrew and Greek documents, which had for centuries been superseded by the Vulgate. But in spite of the enlightened principles which it laid down as the basis of exegesis, it was still, almost as much as Roman Catholicism, the victim of the dogmatic method. It started from the assumption that the Bible is primarily a text-book of theology, and since it was verbally or at any rate plenary inspired, there must be a uniform system of theology in all the parts of Scripture. Luther was much more advanced in his treatment of Scripture than most of his followers. When a book of Scripture did not yield the results he wished to find, he boldly questioned its authority. He regarded the Epistle of James, for instance, as an 'epistle of straw,' because it did not seem to support his fundamental doctrine of 'justification by faith.' The later reformers, however, refused to follow him in this free treatment of the Word. By exegetical devices and tortuous methods of interpretation, by the exploitation of the principle of symbolism in the Old Testament, for instance, they managed to discover the evangelical doctrines in every book of the Bible. They laid down the principle that every verse of Scripture must be interpreted in relation to the general teaching of the whole, and if the surface meaning of a text seemed to be in opposition to some cherished doctrine, it was obvious that the surface meaning was wrong, and it was then the business of exegesis to discover another meaning for the words which would bring them into harmony with the general evangelical position.

The transition from the dogmatic to the historical method of exegesis was slow and gradual, and it cannot be said that the dogmatic method is altogether destroyed to-day. We are under a great debt to Schleiermacher, who in the initial stages gave a great impulse to the historical method. Schleiermacher challenged the position that the Bible is merely a compendium of proof-texts, and urged that each particularly should be studied by itself, without any preconceived ideas as to what its teaching ought to be. 'No biblical book,' he says, 'can be perfectly understood except as it is studied with

reference to the whole environment out of which it grew, and in connection with the circumstances of its author and readers.' The old assumption that a uniform body of doctrine is to be found in each document of the Bible is now completely abandoned. Modern criticism has achieved great results by reconstructing the circumstances under which each book was written, and relating it to the general situation which prevailed at the time of its production. The application of the category of evolution to the Old Testament has made it a new book. We no longer look for the Sermon on the Mount in Amos, or the theology of St Paul in the Psalms. The question we ask is, How did the religious development of Israel produce the 'fullness of the times' which made the Sermon on the Mount and the theology of St Paul possible?

The principles upon which scientific exegesis works to-day may be summarised as follows:

(1) First of all, it is necessary to settle, as far as possible, the true text of the Bible. There are many variant readings in the Old Testament and vastly more in the New, and it is necessary, by the application of the principles of the science of textual criticism, to determine which reading represents what was originally written by the author of the document.

(2) Having determined the text, it is necessary, by the application of the latest grammatical principles and lexicographical discoveries, to find out the plain sense of the passage—i.e. the meaning which it possessed for writer and reader when it was first composed. The advance which has been made in Semitic studies and the epoch-making 'finds' of Greek papyri have introduced revolutionary results in this particular branch of exegesis. As a result, we shall be able to obtain a true translation of the book—i.e. a translation which is a real equivalent in English (as far as that is possible) of the original document.

(3) Having obtained our translation, the next task of the exegete is to relate the document to the environment in which it was produced. The one fact which must never be lost sight of is that each book was written to meet the specific needs of its own age. The apostle Paul, for instance, in each of his epistles deals with the problems, both intellectual and practical, which confronted the Church in the 1st century. The prophet Isaiah faced a situation which was created by the special circumstances of the time in which he lived. Neither Paul nor Isaiah nor any other biblical writer ever imagined that he was writing a document which would be treated as inspired literature and used as source of Christian theology throughout the centuries. It is absolutely necessary to find out what the message of a book was for its own age, before we can discover the elements in its teaching that are of eternal value.

(4) It is necessary to ask a further question, How far was the writer influenced in his conception or interpretation of religion by the current thought and language of his times? The revelation of God never fell upon a *tabula rasa*—it was refracted in a mirror that was always more or less imperfect, and generally warped by influences and conditions of the age. Allowance must be made for the personal equation of the prophet and apostle. In the spiritual region as well as in the physical, the mind sees what it brings with it the power of seeing; and in the interpretation of what has been seen, the writer is restricted by the categories and thought-forms of his time. No writer can therefore be fully understood unless his statements are interpreted in the light of the larger context of the intellectual and moral outlook of his time. The Epistles of St Paul would have assumed a very different form if they had been written for the first time in

the 20th century, and his ideas would inevitably have taken very different shape. It is not enough, therefore, for the exegete to translate the epistles out of one language into another; he is bound to attempt to translate the ideas as well out of one universe of thought and experience into another. This is the modern ideal that exegesis sets before itself—and though the task involves the utmost knowledge, sympathy, and insight, the results are worth the labour. The gain in our understanding of the Bible is already very great, and modern scholarship is as yet only at the beginning of its work.

See articles on BIBLE, BIBLICAL CRITICISM, INSPIRATION, REVELATION.

Exelmans, REMY JOSEPH ISIDORE, COMTE, a distinguished French general, was born at Bar-le-duc, 13th November 1775. Entering the army in 1791, he served with distinction in the campaign of Naples under Championnet, was made general of brigade after Eylau, and followed Murat to Spain, where he was taken prisoner and sent to England. For his conduct in the disastrous Russian campaign Napoleon created him a general of division. Exelmans seems to have been equally esteemed under every successive government. On the fall of Napoleon, he was for some time banished from France, but was permitted to return in 1823. In 1831 Louis-Philippe restored his titles and rank. Louis Napoleon named him Grand Chancellor of the Legion of Honour, and in 1851 raised him to the dignity of Marshal. On the 21st July 1852 Exelmans had a bad fall from his horse, from the effects of which he expired on the following night.

Exempla. See FABLE.

Exequatur. See CONSUL, PLACITUM REGIUM.

Exeter, the capital of Devonshire, 171 miles by rail WSW. of London, and 75 SW. of Bristol. Dominated by higher hills, it is built on the summit and slopes of a flat ridge, rising 150 feet from the left bank of the Exe; and, having been modernised chiefly in its suburbs, it is a pleasant antique city—'as good a specimen of an English county town, at once prosperous in business, and with a quiet air of aristocratic distinction, as can be found within the four seas' (Escott's *England*). The quaint old High and Fore Streets, crossed by North and South Streets, still follow the line of the Ickneld Way; and the walls in great part remain, though their four gateways were demolished between 1769 and 1819, and though Rougemont Castle (1068) was almost all swept away in 1774, to make room for an ugly assize-hall. In 932 Athelstan founded here a Benedictine monastery, and thither in 1050 Edward the Confessor translated the western bishopric from Crediton; but St Peter's Cathedral was not begun till sixty-two years afterwards. Measuring 408 feet by 76 (or 140 across the transepts), and 66 feet high, it is a long, low edifice, with massive transeptal towers—a feature imitated at Ottery St Mary, but otherwise unique. These towers, 140 feet high, are the original Norman ones, but the rest of the pile, rebuilt between 1280 and 1369, is mainly in the purest Geometrical Decorated. The most striking characteristics of the whole are its perfect bilateral symmetry and the grand unbroken line of vaulting. Special features are the exterior western screen (*circa* 1388), adorned with sixty-seven statues of saints and princes; the beautiful choir-screen (1324), surmounted by the fine organ (1665); the minstrels' gallery (1353); the misereres, sedilia, and bishop's throne; the modern reredos, stall-work, and pulpit; a clock, dating from 1317 or earlier; the Great Peter bell, brought from Llandaff in 1482, recast in 1616, and weighing 12,500 lb.; and the chapter-house (1420-78), containing 8000 MSS. and early books. Im

1870-77 the cathedral was restored by Sir G. G. Scott; in 1889 the cloisters and library. The picturesque guild-hall (1464) has a cinque-cento façade (1593); noteworthy modern buildings are the Devon and Exeter Hospital (1743), the Lunatic Asylum (1865), and the Albert Memorial Museum (1868). The chief public walk is Northernhay. A ship-canal (1563-1827) extends 5 miles to the tideway at Topsham. Exeter has a University College (new buildings, 1911; others proposed on Sleatham Hall estate). It manufactures gloves, agricultural implements, &c., besides being the chief mart of 'Honiton' lace. Its woollen trade, once second only to that of

Judicious Hooker, Sir Thomas Bodley, and Henrietta, Duchess of Orleans.

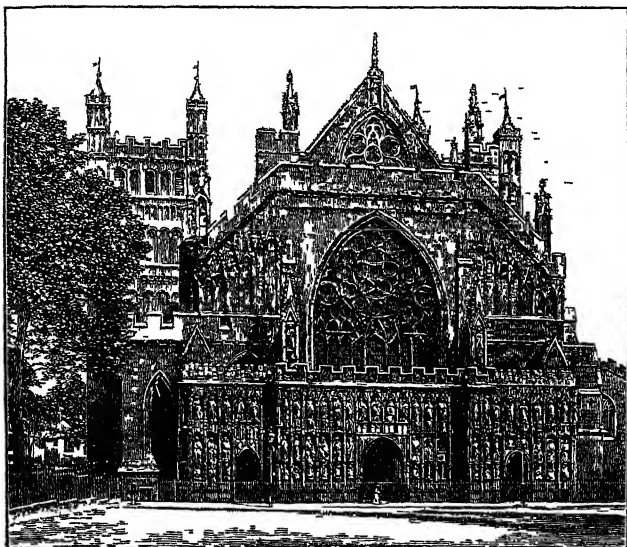

Exeter, PEERAGE OF. See BURGHLEY.

Exeter Book, or CODEX EXONIENSIS, an Old English folio manuscript, dating probably from the first half of the 11th century, presented between 1050 and 1072 to Exeter Cathedral by its first bishop, Leofic. It consists of some legal documents, from eighty to ninety riddles, and an anthology of poetry, containing, as in *Christ*, some of the finest extant specimens of Old English verse. Dates of composition vary, but the poem *Widsith* is certainly older than *Beowulf*. See works by B. Thorpe (1842), and Sir I. Gollancz (1895).

Exeter College. See OXFORD.

Exeter Hall, a large proprietary building, on the north side of the Strand, London, was completed in 1831, and could contain upwards of 5000 persons. It was let chiefly for religious assemblies, and was in great request during the 'May Meetings' of the several religious societies. It was also the scene of many great musical fêtes. In 1880 it was purchased for the Young Men's Christian Association, and in 1908 it was demolished.

Exhibitions. The earlier beginnings of Industrial Exhibitions, like all great movements, are not particularly easy to define. The first exhibition of anything like national importance, however, seems to have been the one originated by the Marquis d'Aveze at Paris, 1798, though previous to this a show of agricultural and other machinery had been held by the Society of Arts in London (1756), and another exhibition had been given

Exeter Cathedral: West Front.

Leeds, is a thing of the past; and as a seat of commerce and industry it has been outstripped by many a younger competitor. The 'ever loyal city' got its earliest charter from Henry II. some time prior to 1162; in 1537 was made a county of itself; and it returned two members from about 1300 till 1885, when their number was cut down to one. Pop. (1891) 37,404; (1911, as extended in 1900) 48,664; (1921) 59,608.

The Celtic *Caerwisc*, the Roman *Isca Damnoniorum*, and in 876 the *Exanceaster* of the West Saxons, who till 926 shared it with the Britons, Exeter, in Freeman's words, 'is the one great city of the Roman and the Briton which did not pass into English hands till the strife of races had ceased to be a strife of creeds, till English conquest had come to mean simply conquest, and no longer meant havoc and extermination.' To Freeman's pages reference must be made for its capture by the Danes (876 and 1003), by William the Conqueror (1068), and by Stephen (1136); for its siege by the Yorkists (1470), by Perkin Warbeck (1497), and by the Catholic rebels (1549); for its surrender to Prince Maurice (1642) and to Fairfax (1646); and for the entry of William of Orange (1688). Whereto must be added the tragic burning of the new theatre (5th September 1887), with a loss of 188 lives. Among bishops of Exeter have been Leofic (1050-72), Bartholomew (1161-84), Stapledon (1308-26), Grandison (1327-69), Miles Coverdale (1551-53), Joseph Hall (1627-41), Seth Ward (1662-67), Trelawny (1689-1707), Phillpotts (1831-68), Temple (1869-85), Lord Hugh Cecil. Natives were Archbishop Baldwin, Cardinal Langton (doubtfully), John Vowel or Hoker, the historian of Exeter (1525-1601), the

at Prague in 1791. A second exhibition of greatly improved kind was opened at Paris in 1802; a third in 1805; and hence arose the custom of holding such displays triennially, continued with slight interruption for half a century. It should be mentioned that the specimens exhibited on these occasions were essentially of French production, and care was taken to exclude any article of foreign character. The impetus given to the movement by the Paris displays was felt over Europe, and reached the United States. Between the years 1820 and 1850 exhibitions were held at Vienna, Berlin, Brussels, St Petersburg, Stockholm, Moscow, Lisbon, Madrid, New York, Philadelphia, and numerous other towns. Nor did the United Kingdom escape the infection, though here the promoters of such undertakings had to struggle against much apathy and even opposition. To Ireland belongs the credit of the first display of noticeable merit. This was the Exhibition of Irish Industries, held by the Royal Dublin Society at their rooms in 1829, and the association continued the practice triennially for several years. The Society of Arts in London also held a number of exhibitions illustrative of the manufactures, commerce, and agriculture of the country, and the Cornwall Polytechnic Society energetically laboured in a similar direction by holding periodical exhibitions to illustrate the mineral wealth of that county, and the mechanical appliances necessary for mining. From this may be said to have originated the happy idea of holding in various large towns exhibitions descriptive of the industrial work carried on in the locality. Manchester led the way with a display of everything concerned in the manufacture of

cotton; Liverpool followed with an exhibition of the raw produce brought to that seaport, and the shipbuilding that rendered such trade possible; Leeds held an exhibition of the material and processes involved in the flax and woollen trades; and Birmingham (1849) fairly surpassed them all with an excellently arranged show of the numerous useful and ornamental forms into which metals can be wrought. The Birmingham Exhibition may be said to have had an important influence in bringing about the first great exhibition of 1851.

For some time past the English government had been urged without success to organise an exhibition in London of a really national character, illustrating the arts of Great Britain and Ireland. In the spring months of 1849 the Society of Arts, being greatly influenced in the matter by Prince Albert, sketched the outline of a great exhibition of the industries of all nations, and proposed that such exhibition should be held at London in 1851. It was held in Hyde Park in a vast structure of iron and glass, called the Crystal Palace (q.v.; now located at Sydenham), and planned by Sir Joseph Paxton (q.v.). The exhibitors numbered nearly 15,000, about equally divided between British and foreign contributors. The entire number of visitors was over 6,000,000, or about 42,000 per day. The total receipts amounted to £505,107, leaving a surplus of £200,000.

The second great international exhibition of 1862 was held in a building at South Kensington, occupying together with its annexes, and two cupolas of great magnitude, an area of about 24 acres. The total number of exhibitors was 28,653, of whom 26,348 were in one or other of thirty-six industrial classes, the remainder in one or other of four fine art classes. The visitors numbered rather more than in 1851, but the daily average was less. There was a deficit of about £10,000.

In 1867 came the Paris Exhibition, which in its general arrangement and magnitude of conception surpassed anything that had yet taken place. The building was a vast oval, 1550 feet by 1250, with a series of twelve concentric galleries running round it, and a small garden in the centre. In each gallery a separate branch of science and art was illustrated, and the entire oval was divided into sections, one of which was devoted to each country. The complete exhibition covered close on 100 acres. The number of exhibitors was 50,226, and the total expense £800,000, half of which was defrayed by the public attendance, half by the imperial government and the Paris municipality; visitors were 10,200,000. Britain did not figure very favourably in this exhibition—probably by reason of the want of technical education—whereas Germany, France, and Belgium showed a marked advance. The Vienna exhibition in 1873 was a huge financial failure.

In 1871 the first of a series of annual London International Exhibitions was opened. The movement, however, never became popular, and was relinquished in 1874. The next most important display after Vienna was the Philadelphia Centennial Exhibition of 1876, held in commemoration of the hundredth anniversary of American Independence. The main building, in the form of a parallelogram, covered a floor-space of about 20 acres. One centre and two side avenues ran along the inside of the edifice, the former being 1832 feet long by 120 feet wide—the longest avenue of that width ever known in an exhibition structure. The number of exhibitors fell below those of the preceding exhibitions at Paris and Vienna—in all about 40,000. The building was open to the public on 139 days, and the total attendance of visitors was 9,910,966; receipts, \$4,300,000—a sum much below the expenditure. The Paris International Exhibi-

tion of 1878 again made an advance in magnificence and size upon all previous displays. The total area covered by the various buildings was about 80 acres, the exhibitors numbered 80,000, and the visitors 16,032,725. The Universal Exhibition of Paris in 1889 excelled all its predecessors in point of magnitude and comprehensiveness; with the included grounds it occupied an area of 173 acres. The Eiffel Tower (q.v.) was one of the principal attractions of the exhibition. Still grander in conception and scope was the World's Columbian Exposition held at Chicago in 1893, on the fourth centenary of the discovery of America by Columbus; it was attended by some 25,000,000 visitors. The Paris Exhibition of 1900 was based on a scale sufficiently vast to mark worthily the completion of the century; in the 20th were those of Glasgow, St Louis, London (Franco-British), San Francisco (Panama-Pacific), Wembley, &c. Many exhibitions have been devoted to special activities—the book-trade, town-planning, fisheries, the empire, and the like; and local industries have had their frequently recurring exhibitions, called fairs.

Exile. See BANISHMENT.

Ex-Libris. See BOOKPLATES.

Exhumation. It is a misdemeanour to disinter a dead body without lawful authority, whether for sale, dissection, or reinterment. If only reinterment in other consecrated ground is contemplated, a faculty from the ordinary of the diocese may be obtained for that purpose. In cases of suspected foul play, the coroner (or corresponding legal authority in Scotland) may order disinterment for medical inspection, or for further examination in connection with possible criminal proceedings. Otherwise no body may be disinterred without the license of the Secretary of State, under a penalty not exceeding £10. See also POST-MORTEM EXAMINATION, RESURRECTIONISTS.

Exmoor Forest, in the west of Somersetshire and north-east of Devon, is a wild, mostly uncultivated waste, consisting of long ranges of steep hills and lonely valleys, and bordered by deep wooded glens. The hills rise in Dunkery Beacon to 1707 feet, in Chapman Barrow to 1540, and in Span Head to 1610. The 'forest' proper is about 25 miles in area, but with the adjacent commons Exmoor extends over 100. The rocks belong to the Devonian series, mainly slates and sandstones. Hence the outlines are less bold and rugged, and the general aspect far less stern and desolate than that of Dartmoor, ribbed and spread with granite. Though 'improvements' were attempted in 1818, and many trees planted by Mr J. Knight, who had purchased the forest from the crown, Exmoor is still in the main covered with grass (in some parts short and sweet, in others rank and sedgy), bracken, and heather, with dangerous bogs near the hill-tops. Where it ranges down to the coast near Lynton, the scenery is very bold and picturesque. The Exe, Barle, Mole, and the two Lyns are the chief streams rising here. Gold has been found in Northmolton parish, and copper-mines have been worked there from time to time. There is a native breed of very small ponies, known as Exmoor ponies, stout and hardy, as well as a local breed of horned sheep of high quality. The most notable feature of the fauna of Exmoor is, however, that it is the only place in England where red deer still run wild. They are now becoming numerous. Stag-hounds have been kept here and stag-hunting followed since at least 1598. Sir Thomas Acland in 1917 gifted to the nation a 500 years' lease of Exmoor. Exmoor is the chief scene in Blackmore's *Lorna Doone*, which abounds in admirable descriptions. See also Hall's *Exmoor* (1849), Collyns's *Chase of the Wild Red*

Deer (1862), Rawle's *Annals of Exmoor* (1894), Snell's *Book of Exmoor* (1903), MacDermot's *Forest of Exmoor* (1911), and DEER FORESTS.

Exmouth, a Devonshire watering-place, at the east side of the mouth of the Exe, 11 miles by rail SSE. of Exeter. A sheltered spot, with fine climate, good beach, and beautiful views, it had dwindled from a considerable seaport to a poor fishing-village, when, about the beginning of the 18th century, it rose into repute as a seaside resort; and now it has terraces, hotels, baths, promenades, and pleasure-grounds along the seashore, and docks, constructed in 1869. Lace-making and fishery are the main pursuits. Pop. (1851) 5123; (1921) 13,614.

Exmouth, EDWARD PELLEW, VISCOUNT (1757-1833), an English admiral, was born at Dover. He entered the navy at the age of thirteen, and first attracted notice by his gallant conduct in the battle on Lake Champlain in 1776. In 1782 he attained the rank of post-captain. In 1793, having been appointed to the command of the *Nymph*, a frigate of thirty-six guns, he encountered, and, after a hard-fought battle, captured *La Cléopâtre*, a superior French frigate. For this victory he was knighted; and in 1796, for acts of personal bravery, he was created a baronet. In 1798 he received the command of the *Impétueux*, and was sent to the French coast, where many of his most brilliant actions took place. In 1804 he was appointed rear-admiral of the Blue, and commander-in-chief in India, from whose seas he drove the French cruisers; he was afterwards made commander-in-chief in the North Sea and in the Mediterranean. In 1814 Pellew was created Baron Exmouth of Canonteign, in Devonshire, with a pension of £2000 a year. In 1816 he was sent to Algiers, to enforce the terms of a treaty regarding the abolition of Christian slavery, which the Dey had violated. With a combined fleet of twenty-five English and Dutch vessels, he bombarded the city for nine hours, and inflicted such immense damage, destroying all the Algerine fleet and many of the public buildings, that the Dey consented to every demand. For this service he was raised to the rank of viscount. See his *Life* by Osler (1835), and Mahan's *Types of Naval Officers* (1902).

Exocetus. See FLYING-FISH.

Exodus, the second book of the Pentateuch. It describes the oppression of the Hebrews in Egypt, the birth and early life of Moses, the ten plagues, the exodus or departure from Egypt, the crossing of the Red Sea and the destruction of Pharaoh's army, the march to Sinai, the giving of the law, the episode of the golden calf, the construction of the Tabernacle. Like the other books of the Pentateuch, Exodus is made up of three documents, known as (a) the Jahvist, (b) the Elohist, (c) the Priestly Code (see PENTATEUCH, BIBLICAL CRITICISM). To what extent the narrative is historically accurate is a matter of dispute among modern scholars. There are considerable difficulties in fixing the date at which the exodus from Egypt took place. The traditional view places it in the reign of Merenptah (1234-1214 B.C.), the main basis on which this theory rests being the statement in Exod. i. 11, about the building of the 'store-cities,' since we know from the inscriptions that building operations were carried out at Piithom by Rameses II. (1300-1234 B.C.), the predecessor of Merenptah. Other data (e.g. the statement in 1 Kings, vi. 1) assume an earlier date for the event. See EGYPT, p. 242; JEWS, p. 330. The best popular commentaries are Bennett's (*Century Bible*) and Driver's (*Cambridge Bible*).

Exogamy, the usage by which among many primitive peoples a man may not marry a woman of

his own stock or tribe or section thereof. See FAMILY, MARRIAGE.

Exogenous Plants, or EXOGENS, a term applied by Lindley to Dicotyledons (q.v.). See also BARK, CAMBIUM, MONOCOTYLEDONS.

Exophagy. See CANNIBALISM.

Exorcism, the term used by the Fathers of the Church to denote the act of conjuring evil spirits, in the name of God or Christ, to depart out of the person possessed. The first Christians adjured evil spirits in the name of Jesus Christ, who had conquered the devil; but as the opinion was at the same time entertained that all idolaters belonged to the kingdom of Satan—who suffered himself to be worshipped under the form of idol—it was customary to exorcise heathens previous to their receiving Christian baptism. After Augustine's theory of original sin had found acceptance in the 5th century, and all infants were regarded as belonging to Satan's kingdom, exorcism became general at the baptism even of Christian children. Following the practice of the Roman Catholic Church, Luther retained it, and the baptismal office in the first prayer-book of Edward VI. (1549) contained a short form, omitted at Bucer's intervention in the 1552 revision. The seventy-second canon (1603) of the Church of England forbids any minister attempting to expel a devil or devils, without first obtaining the license of his bishop. Although abandoned by illustrious and orthodox Protestant theologians, such as Chemnitz and Gerhard, or deemed unessential, and in modern times done away with by the 'Protestant' Church, since 1822 baptismal exorcism has been revived by the Old Lutheran or High Church party.

In the Catholic Church the function of exorcism belongs peculiarly to the third of the so-called 'minor orders' (see ORDERS). Our Lord having not only himself in person (Matt. ix. 32; Mark, i. 25; Luke, iv. 35, viii. 29) cast out devils, but having also given the same power to his disciples, it is believed to be permanent in the church. Of its exercise in the early church, both in relation to 'energumens,' or persons possessed, and in the administration of baptism, there are numerous examples. Tertullian and Origen speak of it as of ordinary occurrence, and the Council of Carthage, in 255, alludes to its use in baptism. The rite of exorcism is used by the modern church in three different cases: in the case of actual or supposed demoniacal possession, in the administration of baptism, and in the blessing of the chism or holy oil, and of holy water. This last practice is alluded to by Cyprian (Ep. 70). The use of exorcism in cases of possession is now extremely rare, and in many diseases is prohibited, unless with the special permission of the bishop. In baptism it precedes the ceremony of applying the water and the baptismal form. It is used equally in infant and in adult baptism, and Catholic writers appeal to the earliest examples of the administration of the sacrament as evidence of the use of exorcism in both alike. The rite of baptismal exorcism in the Roman Catholic Church follows closely the Scriptural model in Mark, viii. 33. The exorcisms in the blessing of the oil and water resemble very closely the baptismal form, but are more diffuse. See WITCHCRAFT.

Exosmose. See OSMOSE.

Exostenma, a West Indian genus nearly allied to Cinchona, for which its bark was formerly introduced as a substitute; it does not, however, contain the Cinchona alkaloids.

Exostosis, a term for a protuberance or morbid enlargement of a bone.

Exoteric. See EXOTERIC.

Exotic Plants, or EXOTICS (Gr., 'coming from

abroad'), cultivated plants originally derived from foreign countries. The term is most frequently applied to those whose native country differs so much in soil or climate from that into which they have been conveyed that their cultivation is attended with difficulty, requiring artificial heat or other special means. See GARDENING.

Expansion. See HEAT, BRIDGE.

Expectation of Life. See PROBABILITY, ANNUITY, INSURANCE.

Expectorants (Lat. *ex*, 'out of,' and *pectus*, 'the breast'), medicines given to carry off the expectorations—the mucus and other secretions of the air-tubes. The principal expectorants are antimony, ammonia, squill, ipecacuanha, senega, balsam of tolu, lobelia, gum ammoniac, asafetida, galbanum, &c. The examination of the expectoration is of great value in the diagnosis of diseases of the chest (see BRONCHITIS, PNEUMONIA, CONSUMPTION). The word 'expectoration' has come by an abuse to be regarded as a mere elegant synonym for spitting. See SALIVA.

Expenses or Costs of a Lawsuit. In Scotland, the charges payable by the parties to a lawsuit are technically called expenses. The rules according to which they are awarded, apportioned between the parties, and taxed, do not differ materially from those applied in England to Costs, and explained under that head, *supra*. The Scottish official who discharges the functions of taxing master is the Auditor of Court. If the agent who has conducted the cause wish it, the decree for expenses will be pronounced in his favour; and the party found liable will not be allowed to plead a counter-claim against the client, as by that means he might prevent the agent from recovering what he very probably has disbursed.

Experiment. See SCIENCE.

Expert, a man of special practical experience or education in regard to a particular subject—a word commonly applied (after the French) to medical or scientific witnesses in a court of justice, when selected on account of special qualifications, as in the case of an analysis of the contents of the stomach in suspected poisoning. The term is similarly applied to a person professionally skilled in handwriting, for detection of forgery of deeds and signatures (see WRITING).

Exploration. See GEOGRAPHY, POLAR EXPLORATION; also AFRICA, &c.

Explosion. See GUNPOWDER, MINING.

Explosives, a term used of gunpowder, gun-cotton, dynamite, nitro-glycerine, cordite, melinite, &c., treated under their several heads. Other high explosives are dealt with along with dynamite. See also BLASTING, BOMBS, FIRE-ARMS, MINING, BULLET, GENEVA, MINES, TORPEDO, &c.

Whoever unauthorisedly introduces explosives into a building is responsible for damage caused. The tenant of a house is answerable for the damage caused by an explosion of gas on the premises, if gas escapes through the negligence of himself or his servants in attending to the stopcocks by which the supply of gas is regulated. Under the Explosives Act, 1875, any person throwing, casting, or firing any fireworks in or into any highway, street, thoroughfare, or public place, is liable to a penalty of £5. Any person unlawfully and maliciously causing, or attempting or conspiring to cause, an explosion likely to endanger life or seriously to injure property, is guilty of felony. It is also felony to make, keep, or have in one's possession any such explosive under circumstances indicating unlawful intent, unless the defence dispels the suspicion. The chief enactments are the Explosives Act (which regulates the manufac-

ture, storage, keeping, selling, and conveyance of nitro-glycerine, dynamite, gun-cotton, and other explosives), the Petroleum Acts, 1871 and 1879, and the Petroleum (Hawkers) Act, 1881. All factories and stores of gunpowder and other explosives must be licensed, and all places where explosives are kept must be registered. The sale of gunpowder to any child apparently under thirteen is prohibited. Government inspectors, officers of local authorities, and constables may search for and seize explosives unlawfully kept, in ordinary cases with a warrant, and in cases of emergency with a written order from a superintendent of police. The master of every ship which enters a British harbour must, if the ship carry petroleum, give notice of the fact to the harbour authority, which, under confirmation of the Board of Trade, makes bylaws regulating the landing of petroleum. Petroleum to the amount only of three gallons may be kept for private use or sale without a license, if it is kept in separate glass, metal, or earthen vessels, securely stopped, and each containing not more than a pint.

Exponents, or INDICES. The product $5 \times 5 \times 5 \times 5$ is expressed thus, 5^4 , and the eighth power of a thus, a^8 . The numbers 4 and 8 are the exponents of these respective powers. In general, a^n (where a is any number or expression) stands for the n th power of a —i.e. the product of n factors each = a , and there the value of this contracted notation is obvious. Introduced by Descartes, the theory of indices was speedily extended, and may now be said to affect algebraic operations of every conceivable kind. The two fundamental laws of indices are $a^m \times a^n = a^{m+n}$, and $(a^m)^n = a^{mn}$. These, with certain necessary conventions, apply to all possible values of the exponents m and n —integral or fractional, positive or negative, simple or complex, rational or surd, real or impossible, trigonometrical or logarithmic, &c. Minor results of the theory are such as these:

$a^0 = 1$, whatever a may be; $a^{-s} = \frac{1}{a^s}$, or a^{-n} is the reciprocal of a^n ; $a^{\frac{1}{2}} = \sqrt{a}$, $a^{\frac{1}{3}} = \sqrt[3]{a}$, $a^{\frac{1}{4}} = \sqrt[4]{a}$ = $(a^{\frac{1}{2}})^{\frac{1}{2}}$. An exponential equation is one in which the x or y occurs in the exponent of one or more terms, as $5^x = 800$. Its solution generally requires the use of logarithms. The exponential theorem gives a value of any number in terms of its natural logarithm, and from it can at once be derived a series determining the logarithm.

Exposure. See INFANTICIDE.

Express, a system organised for the speedy transmission of parcels or merchandise of any kind, and their safe delivery in good condition, originated in the trip made from Boston to New York by William Frederick Harnden (1813-45), the first 'express-package carrier,' on 4th March 1839. The project recommending itself to business men, competing companies sprang up rapidly, and express lines were established in all directions. Adams & Co.'s was started in 1849; Wells, Fargo, & Co.'s California express in 1852; the American-European company was created in 1855. As railways extended, the early 'pony express' disappeared, and individual companies now have contracts with the several railway companies, their business over these routes being held to be entitled to the protection of the courts against any efforts to dispossess them. Many of the rival companies were amalgamated, and most of the successful concerns are now joint-stock institutions, the industry employing capital aggregating many millions of pounds. Goods can be sent to strange firms at a distance marked C.O.D., with the amount to be collected on the outside of the package, and the

payment is collected by the express company, which receives a slight compensation for this extra trouble. Much use is made of money-orders sold by express companies.

Expressionism, in literature and painting, is a revolt against the passive receptivity of Impressionism. 'The rising generation, says Hermann Bahr, 'turns away from the outer life to the inner; listens to the voices of its own hidden nature; and believes that man is not a mere echo of his world, but its creator, or, at all events, is as strong as it is.' The expressionist despises the copying of actuality, and uses it only as a means of expressing his own emotion. Many of the best writers of 20th-century Germany are or have been expressionists.

Extension, a term in Logic, opposed to *intension*, referring to the extent of the application of a term, or the number of objects included under it. The greater the extension of a term, the less is the intension; and the greater the intension or comprehension (the common characters included in a term), the less is the extension.

Extent. To extend is, in English law, to make a valuation of property by the oath of a jury. A writ of extent directs the sheriff to 'extend' and seize the property of a debtor. Such writs are now issued only for the recovery of debts of record due to the crown. In Scotland 'extent' (often shortened to 'stent') was used to denote the general valuation of lands for taxation, &c. For the old and new extent, see VALUATION. Writs of extent were formerly issued for the recovery of crown debts; and the English form of process was introduced, in revenue cases, by the Act of Union. In America extent is a process whereby the lands of a debtor are delivered to his creditor until the debt is paid out of the profits.

Extenuating Circumstances. When a crime is committed, those circumstances, in connection either with the position of the prisoner or with the act alone, which are taken into consideration by the court in mitigation of the punishment are popularly called extenuating circumstances. The previous good character of the person convicted may always be proved as a circumstance giving him some claim to leniency of punishment. Besides character, there are other circumstances, the presence of which in a case sometimes serves to mitigate the sentence, sometimes to take the act done out of the category of crime altogether. One is youth. Thus, no act done by any person under seven years of age is a crime. Defective mental power in the person convicted will always be considered in determining the severity of his sentence. Such disease of mind as prevents a man from knowing that the act he does is wrong will excuse him from the consequences of an act otherwise criminal. Thus, if one man kill another under the insane delusion that he is breaking a jar, the act is not a crime. Drunkenness, when voluntary, is not held an extenuating circumstance, but if a man is made drunk by the fraudulent administration of drugs, and while under their influence kills another, not knowing what he does, the act is not a crime. It is a good excuse for persons charged with crime that they have been compelled by others by threats of death or great violence to do the criminal act. Ignorance of the law is no excuse for an offence. Thus, a foreigner, not knowing the law of England, might kill a man in a duel, and suppose that he had done nothing unlawful. But he would be guilty of murder. Nor, in general, will ignorance of facts be a good excuse, although in particular circumstances it might form a valid defence. Thus, if a man pretended in a joke to be a robber, presented a pistol at the head of a traveller, and demanded his money, and the

traveller, believing himself to be attacked by a real robber, shot and killed the pretended robber, his act would be held as justified. Sir James Fitzjames Stephen (*Digest of the Criminal Law*) states, in language purposely vague, to represent the vagueness of the law, a principle under which the stress of necessity is held to excuse acts otherwise criminal. He says: 'An act which would otherwise be a crime may in some cases be excused if the person accused can show that it was done only in order to avoid consequences which could not otherwise be avoided, and which, if they had followed, would have inflicted upon him or upon others whom he was bound to protect inevitable and irreparable evil, that no more was done than was reasonably necessary for that purpose, and that the evil inflicted by it was not disproportionate to the evil avoided.' He gives as an illustration of the principle the case of a governor of Madras who acted towards his council in an arbitrary and illegal manner. The council deposed him and put him under arrest, and assumed the powers of government themselves. That was not an offence if the acts done by the council were the only means by which irreparable mischief to the establishment at Madras could be avoided. He also gives as a further illustration the often figured case of the plank. 'A and B, swimming in the sea after a shipwreck, get hold of a plank not large enough to support both; A pushes off B, who is drowned. This is not a crime.' The principle, however, was not held to cover the case of sailors who probably saved their lives by killing and eating a boy.

Exterritoriality. See EXTRATERRITORIALITY.

Extortion, in Law, is the offence or illegal act committed by a public officer who, under colour of his office, takes from any person any money or valuable thing which is not due from him at the time when it is taken. The act is a misdemeanour, and punishable as such. For example, if the governor-general of India wrongfully compel a native prince to pay sums of money to the Indian government (as was the charge against Warren Hastings), he commits extortion. The term has a special meaning in the criminal law of Scotland, in which it is also applied to the offence of compelling any one by force or fear to do any act which he would not have done of his own consent and inclination. For extortion in the sense of blackmailing, see THREAT.

Extractive Matter is the term applied to the soluble portions of any drug. The substances extracted from the same drug may vary according as the solvent is water, alcohol, ether, &c.; but, so long as the originally insoluble portions are not rendered soluble by the chemical action of the solvent, the term extractive matter is applicable to them.

Extracts, in a technical sense, are medicinal preparations of vegetable principles, got either by extracting these from the plants by means of a solvent or menstruum, and then evaporating the liquid down to about the consistency of honey, or by expressing the juice of the plants and evaporating; this last is properly *inspissated juice*. Extracts, therefore, contain only those vegetable principles that are either held in solution in the juices of the plants themselves, or are soluble in the liquid employed in extracting them, and at the same time are not so volatile as to be lost during evaporation. Now, as many extractive matters are more or less volatile, it makes a great difference whether the operation is conducted at a low or at a high temperature. Besides the loss of volatile constituents by prolonged or excessive heating, extracts become more or less changed and inert owing to the readiness with which vegetable principles are

destroyed when exposed to heat and air. On this account it is usual to avoid evaporation as much as possible, and, where this is impracticable, evaporation *in vacuo* is resorted to. Extracts are called *watery* or *alcoholic* according as the menstruum employed is water or alcohol. Ether is also used in extracting. Different plants, of course, afford different extracts, some being of the nature of bitters, others being used as pigments, tannin, &c.

Liquid extracts are those which are not evaporated so far as to form a paste, and it is usual to make them of such a strength that one fluid ounce contains the active ingredients of one ounce by weight of the drug.

EXTRACT OF MEAT is obtained by acting upon chopped meat by cold water, and gradually heating, when about one-eighth of the weight of the meat dissolves out, leaving an almost tasteless insoluble fibrin. The extract of meat contains the salts and savoury constituents of the meat, and is a light and stimulating article of food (see BEEF-TEA, and BROTH). It may be concentrated into small bulk, and, when desired, may be afterwards treated with water; being heated, it forms an agreeable light soup, though rather stimulating than nutritious. Of this nature is the well-known Liebig's Extract. In order to impart to extract of meat a nutritive as well as stimulant value, the fibrin is sometimes dried and powdered, and, when then incorporated with the extract itself, a product is obtained which represents the original meat in a readily digested form.

Extradition is the surrender of a person accused of crime to the government of a foreign country, within which the crime is alleged to have been committed. The duty of making such surrender has long been acknowledged by civilised nations; but some governments refuse to surrender their own subjects when accused of offences against a foreign law. In England it has been held that no executive officer has authority to surrender any person found within His Majesty's dominions unless empowered to do so by act of parliament. Modern facilities for travelling have made extradition a subject of great importance. In 1843 the British government concluded an extradition treaty with France, and parliament passed an act giving the executive the necessary powers. Since that time treaties have been made by all, or almost all, civilised governments for the surrender of criminals; and even before the extradition treaty with Spain (1878), for example, offenders were given up by the Spanish government—thus in 1872 Bidwell, the bank forger, was extradited by Spain. The British practice is regulated by the Extradition Acts of 1870 and 1873, slightly modified by an Act of 1895. Any police-magistrate may order the detention of a person accused of crime committed abroad on the same evidence as would justify committal of a person accused of crime committed in England. But the person detained is not surrendered until a demand has been addressed to a secretary of state by a diplomatic representative of the government making the demand. The secretary of state may direct a magistrate to inquire into the case; and on such inquiry the prisoner may show that the evidence against him is not sufficient to justify his committal and surrender for trial, or that the crime of which he is accused is not an 'extradition crime'—i.e. not within the treaties and acts which apply to the case. The list of extradition crimes, as fixed by the Act of 1870, includes murder, manslaughter, forgery, larceny, frauds by bankers, extortion by threats, and many other offences. If the magistrate certifies that he has committed the accused, the secretary of state gives a warrant for his surrender, but not until fifteen

days have elapsed; during this interval the prisoner may, if so advised, apply to a superior court for a *habeas corpus*. Political offences are expressly excluded from the category of 'extradition crimes;' but it is to be observed that a political offence does not mean an offence committed from political motives, but an offence committed during a time of civil war or open insurrection (see POLITICAL OFFENCES). A person surrendered on a specific charge may not be tried on any other charge. In 1877 a Royal Commission recommended that treaties should not be considered indispensable, and that British subjects should be surrendered as well as foreigners. It happens sometimes that the person whose surrender is demanded is not a subject of either government—a Spanish subject, for example, may commit crimes in Russia and take refuge in England. In this case the British government would probably not surrender the accused to Russia without obtaining the consent of Spain. In the United States offenders from one State taking refuge in another are usually surrendered by the governor thereof without question; but even in such cases constitutional points of considerable difficulty have sometimes arisen.

Extraordinary Professor (Lat. *professor extraordinarius*) in German universities is of lower status than an ordinary professor.

Extraterritoriality, or **EXTERRITORIALITY**, is the privilege of being considered outside the territory, and exempt from the laws of the country in which one is for the time being resident. It is accorded to foreign sovereigns and ambassadors with their households, to public ships of a foreign power within territorial waters, to foreign troops allowed to pass through the country, in certain cases more generally. For particulars, see **AMBASSADOR**, **CAPITULATION**, **CONSUL**.

Extravasation is the escape of any of the fluids of the living body from their proper vessels (*vas*) through a rupture or injury in their walls. Excrementitious matter thus sometimes escapes into the abdomen through a wound or ulceration of the bowels. But the term is oftenest used in speaking of the escape of blood from injured blood-vessels. Extravasation is distinguished from exudation by this, that in the last the vessels remain entire, and the effusion takes place by filtration through their walls; nor does more than a part of the blood so escape, the coloured blood-corpuscles being retained, while in extravasation perfect blood is effused. Many kinds of extravasation are rapidly fatal, such as that of urine or of the contents of the intestines into the abdomen, or of blood from the vessels of the brain in cases of apoplexy. The dark colour resulting from a bruise is owing to extravasated blood from ruptured capillary or larger vessels.

Extreme Unction, a sacrament of the Roman Catholic Church, which, as the other sacraments supply spiritual aid in the various circumstances of life, is believed to impart to the Christian in death grace and strength to encounter the struggle, as well spiritual as bodily, of the dying hour. The rite of unction in different forms is common to several of the sacraments; the name 'extreme' is given to that of the present sacrament, because it is reserved for the last act of the Christian career. The Council of Trent declares this sacrament, although 'promulgated' in the well-known passage of James, v. 14, 15 (which Protestants regard as having more to do with the general belief in the sanative properties of oil), to have been 'instituted' by Christ. The Fathers frequently allude to the rite of unction, and although many of these allusions certainly refer to the unctions of baptism and confirmation, yet Catholics rely on several passages of Origen, Chrysostom, Cæsarius of Arles, and Pope

Innocent I. as decisive regarding the unction of the dying, as also upon the fact that in the various separated churches of oriental Christians—Greek, Coptic, Armenian, and Nestorian—the rite is found, although with many ceremonial variations. In the Roman Catholic Church the sacrament is administered by the priest, who, 'dipping his thumb in the holy oil, anoints the sick person, in the form of the cross, upon the eyes, ears, nose, mouth, hands, and feet; at each anointing making use of this form of prayer: "Through this holy unction, and His most tender mercy, may the Lord pardon thee whatever sins thou hast committed by seeing, Amen." And so of hearing, smelling, taste and speech, touch, and walking, adapting the form to the several senses.' Extreme unction is reputed by Catholics one of the sacraments 'of the living';—i.e. it ordinarily requires that the recipient should have previously obtained remission of his sins by absolution or by perfect contrition; but it is held to remit, *indirectly*, actual sins not previously remitted, and also (although not infallibly, but according to the merciful designs of Providence) to alleviate, and even to dispel, the pains of bodily disease. The holy oil which forms the 'matter' of this sacrament must be blessed by the bishop—a ceremony which is performed with great solemnity once each year by the bishop, attended by a number of priests, on Maundy-Thursaday. The oil so blessed is reserved for use during the year. In the Greek Church the sacrament is administered by several priests conjointly. The Greeks call this sacrament 'The Holy Oil,' and sometimes 'The Oil of Prayer.'

Extrovert, and **INTROVERT**, in the view of Jung and his followers, the two basal types in human psychology. The fundamental function of the extrovert is feeling, that of the introvert is thought. This distinction, in no sense new or original, has, according to Jung, important bearings on the interpretation of 'repression' in psycho-analysis. The origin of repression Freud finds in sexuality *per se*, but Jung places it on a much wider basis, by tracing it to a natural tendency to adapt to the demands of life one-sidedly; the extrovert adapts by means of feeling, the introvert by means of thought, thought in the first instance and feeling in the second being repressed and necessarily weak; in both cases inequality in development of function results, and this inequality operating in the unconscious brings about a conflict, amounting in certain subjects to a neurosis.

Exumas, comprise Great Exuma, Little Exuma, and the Exuma Keys. See **BAHAMAS**.

Exuvie, a term applied to organic remains, frequently used by the older geologists.

Eyam (pronounced as if *Eem*), a lead-mining village in North Derbyshire, 5 miles N. of Bakewell. Here broke out in September 1665, in its most virulent form, the plague which was then raging in London, and which had been carried hither in a box of clothes and tailor's patterns. William Mompesson, the rector of the parish, aided by Thomas Stanley, who had been ejected in 1662, devoted himself to the care of the dying with the most heroic courage. The plague lingered till the middle of October 1666, and as many as 260 out of a population of 350 perished. Another rector of Eyam achieved a less honourable eminence by living in his vestry for years (till his death in 1705) to evade the consequences of a breach of promise case.

Eyck, **HUYBRECHT** or **HUBERT**, and **JAN VAN**, two illustrious painters of the early Flemish school. They were probably born at Alden Eyck or Maas Eyck on the Maas. Even W. H. J. Weale, in his great work on the brother-painters (1908), has not made the dates and localities of their birth perfectly

certain; but Hubert seems to have been born about 1370, and Jan about 1390. The distinction of being the inventors of oil-painting was wont to be claimed for them, though sufficient evidence has been adduced to show that the method was practised previously. Before their time, however, the custom, particularly in Italy, was to paint with gums or other substances of an adhesive nature dissolved in water, and they were the first who brought into notice and perfected the mode of mixing colours with oil or some medium in which oil was the chief ingredient; while for transparent and brilliant colouring and minute finish their works have never been surpassed. Jan appears to have been instructed in art by his elder brother, and to have painted in conjunction with him as court-painter to Philip of Charolais till 1422, when he entered the service of John of Bavaria, Count of Holland, at The Hague; and in 1425 he was appointed painter and varlet-de-chambre to Philip the Good, Duke of Burgundy, and practised his art chiefly at Bruges. Hubert continued to reside at Ghent, and at the time of his death, on 18th September 1426, was engaged upon a very important altar-piece, with folding-doors, the only work which we can certainly assign to him. It was completed by his brother. Its subject was 'The Adoration of the Lamb,' and it was painted for Jodocus Vyds, who presented it to the cathedral of St Bavon in Ghent. The two central panels, carried off by the French in 1794, were returned in 1815. Of the side panels, two representing Adam and Eve found their way to the Brussels Museum; the rest were sold in 1816, were bought later by the king of Prussia, and were restored to Ghent by the Treaty of Versailles. The masterpieces of the brothers are for the most part in the cities of Ghent, Bruges, Antwerp, Berlin, Munich, and Paris. In the National Gallery, London, are Jan van Eyck's portraits of Jean Arnolfini and Jeanne de Chenany, his wife, standing in the middle of an apartment, with their hands joined—signed and dated 1434; a portrait of a man in a cloak and fur collar, with a red handkerchief twisted round the head as a turban—painted, according to an inscription on the lower part of the frame, 21st October 1433; and a portrait of a man with a dark-red dress and a green head-covering—signed and dated 10th October 1432. In the Louvre is his exquisitely finished 'Chancellor Rollin kneeling before the Virgin.' Jan died at Bruges, 9th July 1440.

MARGARET VAN EYCK, a sister of the two above painters, is mentioned as an excellent artist by Lucas de Heere and Van Manden. A 'Virgin and Child,' in the National Gallery, London, was formerly assigned to her, but is now attributed to an unknown painter of the Early Flemish school. She is believed to have executed the miniatures in the missal of the Duke of Bedford. She died before 1431. See Mrs De Witt's *German and Flemish Masters in the National Gallery* (1904); Sir M. Conway, *The Van Eycks* (1921).

Eye (A.S. *eg*, 'an island'), a market-town and municipal borough in Suffolk, 20 miles N. of Ipswich. It has a fine Perpendicular flint-work church (restored 1869), with a tower 101 feet high, a corn exchange and town-hall (1857), and a grammar-school (restored and enlarged, 1876-82). Till 1885 it returned one member. Pop. 1800.

Eye. In this article we shall consider: (1) The structure of the human eyeball, and of certain accessory parts or appendages which serve to protect that organ, and are essential to the due performance of its functions. (2) The most striking modifications which this organ presents in some of the lower animals. (3) The eye considered as an optical instrument. (4) The action of the retina. (5)

The movements of the eyeballs, and binocular vision.

(1) The *globe of the eye* is placed in the anterior part of the cavity of the orbit, in which it is held in position by its connection with the optic nerve posteriorly, by the muscles which surround it, and by the eyelids in front. It is further supported behind and on the sides by a quantity of loose fat, which fills up all the interstices of the orbit, and facilitates the various movements of which the eye is capable.

The form of the eyeball is nearly spherical; but on viewing the organ in profile we see that it is composed of segments of two spheres of different diameters. Of these, the anterior, formed by the transparent cornea, is more curved, and therefore more prominent. The horizontal transverse diameter

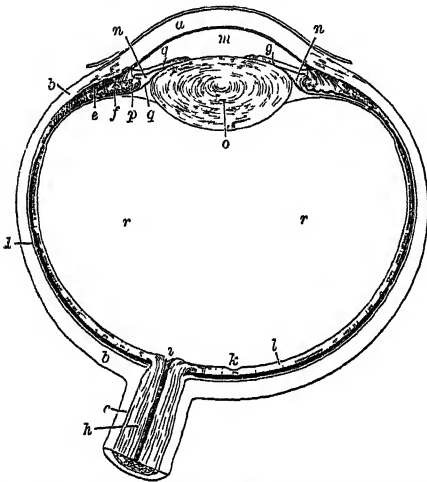

Fig. 1.—View of lower half of right Human Eye, divided horizontally:

a, cornea; *b*, sclerotic; *c*, sheath of optic nerve passing into sclerotic; *d*, choroid; *e*, ciliary muscle; *f*, ciliary process; *g*, *g*, iris; *h*, optic nerve with artery in centre; *i*, passage of nerve into retina, called optic disc or papilla; *k*, fovea centralis; *l*, retina; *m*, anterior chamber of aqueous humour; *n*, posterior chamber of aqueous humour; *o*, crystalline lens; *p*, zonule of Zinn; *q*, suspensory ligament of lens; *r*, vitreous humour.

is almost exactly an inch; the antero-posterior and vertical each about $\frac{1}{4}$ less. The radius of the posterior or sclerotic segment is about half, and that of the anterior segment about three-tenths of an inch.

When the eyes are in a state of repose, their antero-posterior axes are parallel; the optic nerves, on the other hand, diverge considerably from their commissure within the cavity of the skull to the point where they enter the globe; consequently their direction does not coincide with that of the eye. Each nerve enters the back of the globe at a distance of about one-eighth of an inch on the inner side of the antero-posterior axis of the eye.

The eyeball is composed of three concentric membranes, and of certain transparent structures, which are inclosed within them, and which, together with the cornea, transmit and refract the rays of light which enter the eye.

The outer (fibrous or protective) membrane consists of the sclerotic and cornea; the middle (vascular or nutrient) of the choroid and iris; the inner (nervous or percipient) of the retina. The transparent contents are (from before backwards) aqueous humour, crystalline lens, and vitreous humour. We shall consider these structures in order.

The *sclerotic* (from *sklēros*, 'hard'), or 'white of the eye,' is a strong, dense, fibrous structure, covering about five-sixths of the eyeball, and continuous, anteriorly, with the cornea. Posteriorly, it is perforated by the optic nerve, and it is there continuous with the sheath which that nerve derives from the dura mater, the fibrous investment of the brain and spinal cord. Near the entrance of the nerve, its thickness is about $\frac{1}{4}$ th of an inch; from this it diminishes to about $\frac{1}{8}$ th; but in front it again becomes thicker, from the tendinous insertions of the straight muscles which blend with it.

The *cornea* (so called from its hoary appearance) is a transparent structure, continuous with the sclerotic, from which it differs more in appearance than in texture, and completing the fibrous tunic of the eye anteriorly. Its circumference is overlaid by the free edge of the sclerotic, as 'a watch-glass by the edge of the groove into which it is received.' Its thickness is from $\frac{1}{2}$ th to $\frac{3}{4}$ th of an inch. It is covered in front by a layer of conjunctival epithelium, which is exquisitely sensitive.

The cornea, in consequence of its greater convexity, projects beyond the line or the sclerotic; the degree of convexity, however, varies slightly in different persons, and at different periods of life. It is so strong as to be able to resist a force capable of rupturing the sclerotic. The fibrous coat, by its great strength and comparatively unyielding structure, maintains the inclosed parts in their proper form, and serves to protect them from external injuries.

The *choroid coat* is a dark-coloured vascular membrane, which is brought into view on the removal of the sclerotic. Its outer surface, which is nearly black, is loosely connected with the sclerotic by connective tissue, in which are contained certain nerves and vessels—termed the ciliary nerves and vessels—some of which go forward to the iris. Its inner surface is smooth and dark-coloured. In front, it terminates in the *ciliary processes* (figs. 1 and 3), which consist of about sixty or seventy radiating folds or thickenings of the membrane, each of them terminated by a small free interior extremity, and lodged in a corresponding fold in the suspensory ligament of the lens. In other parts, it is covered by the

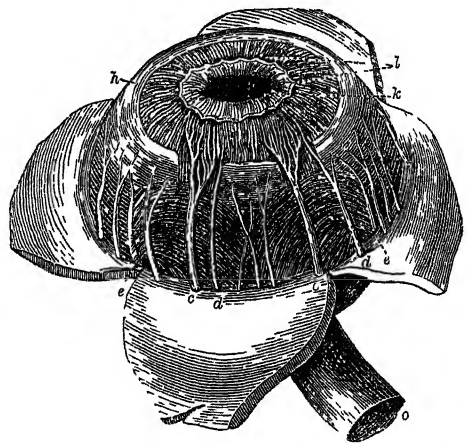

Fig. 2.—Choroid and Iris, exposed by turning aside the sclerotic:

a, *c*, ciliary nerves going to be distributed in iris; *d*, *d*, smaller ciliary nerves; *e*, *e*, veins known as vasa vortices; *h*, ciliary muscle; *k*, *l*, converging fibres of iris; *o*, optic nerve

hexagonal pigment-cells of the retina. The choroid is composed of minute ramifications of vessels—

especially of veins, which, from their whorl-like arrangement, are termed *vasa vorticosa*—of connective tissue, and of large branching pigment-cells. Between the sclerotic and choroid at its anterior part lies a small but important structure, the *ciliary muscle*, which arises from the inner surface of the sclerotic near the cornea, and passes backwards to be inserted into the choroid opposite the ciliary processes.

The *iris* may be regarded as a process of the choroid, with which it is continuous, although there are differences of structure in the two membranes.

It is a thin flat membranous curtain, hanging nearly vertically in the aqueous humour in front of the lens, and perforated by the pupil for the transmission of light. Its anterior surface is variously coloured, and covered by fine irregularly-radiating projections; its posterior surface is smooth, and covered by a

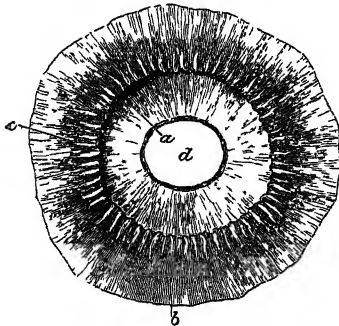

Fig. 3.—Iris and Ciliary Processes from behind :

a, posterior surface of the iris, with the sphincter muscle of the pupil; b, anterior part of the choroid coat, c, one of the ciliary processes, of which about seventy are represented; d, the pupil.

uniform layer of dark pigment, continuous with the pigment-cells of the retina. The posterior surface near the pupil is in contact with the anterior capsule of the lens. It divides the space between the cornea and the lens into an anterior (the larger) and a posterior (the smaller) chamber, these two chambers freely communicating through the pupil (see fig. 1). The outer and larger border is attached all round near the line of junction of the sclerotic and cornea, to the cornea, choroid, and ciliary muscle, while the inner edge forms the boundary of the pupil, which is nearly circular, lies a little to the side of the centre of the iris, and varies in size according to the action of the muscular fibres of the iris, so as to admit more or less light into the interior of the eyeball; its diameter varying, under these circumstances, from about $\frac{1}{4}$ to $\frac{1}{2}$ th of an inch. It is muscular in its structure, one set of fibres being arranged circularly round the pupil, and, when necessary, effecting its contraction, while another set lie in a radiating direction from within outwards, and by their action dilate the pupil. These fibres are of the unstriped or involuntary variety. The nerves which are concerned in these movements will be presently noticed. The iris is richly supplied with blood-vessels; and pigment-cells like those of the choroid are scattered through its substance.

The varieties of colour in the eyes of different individuals, and of different kinds of animals, mainly depend upon the colour and amount of the pigment in these cells. In blue eyes, this pigment is scanty or absent, and the colour is due to the dark pigment of the posterior surface partly seen through the vascular membrane; in brown and black eyes, it is abundant, and is the cause of the colour. In albinos, this pigment is absent from iris, retina, and choroid, and hence their eyes have a pink appearance, which is due to the unconcealed blood in the capillaries of the choroid and iris.

Within the choroid is the *retina*, which, although

continuous with the optic nerve—of which it is usually regarded as a cuplike expansion—differs very materially from it in structure. Before noticing the elaborate composition of this part of the eye, which has only been revealed by microscopical investigation, we shall briefly mention those points regarding it which can be established by ordinary examination. It is a

delicate semi-transparent sheet of nervous matter, lying immediately behind the vitreous humour, and extending from the optic nerve nearly as far as the lens. On examining the concave inner surface of the retina at the back of the eye (see fig. 4), we observe, directly in a line with the axis of the globe, a circular yellow spot (*macula lutea*), of about $\frac{1}{4}$ th of an inch in diameter, called, after its discoverer, the *yellow spot of Sommering*, with a depression in its centre, the *fovea centralis*. About $\frac{1}{3}$ th of an inch internal to this is the entrance of the optic nerve, called the *optic disc* or *papilla*, from which the central artery and vein of the retina may be seen branching as they pass to their distribution.

The structure of the retina, as revealed by the microscope, is in the highest degree remarkable (see fig. 5). Although its greatest thickness (at the entrance of the optic nerve) is only about $\frac{1}{3}$ th of an inch, and as it extends anteriorly, it soon diminishes to $\frac{1}{4}$ th of an inch, the following layers from without inwards can be distinguished in most parts of it: (a) The pigmentary layer, consisting of a single layer of flat hexagonal cells, regularly arranged; its outer surface closely connected with the choroid, its inner in contact with the extremities of the rods and cones. Though its development shows that it really belongs to the retina, its mechanical connection with the choroid is

firmer; and to this it adheres when the retina is stripped off. (b) The layer of rods and cones, frequently termed, from its discoverer, the *membrane of Jacob*; (c) outer granular layer; (d) outer molecular; (e) inner granular; (f) inner molecular; (g) layer of nerve-cells; (h) layer of nerve-fibres, in which the blood-vessels lie.

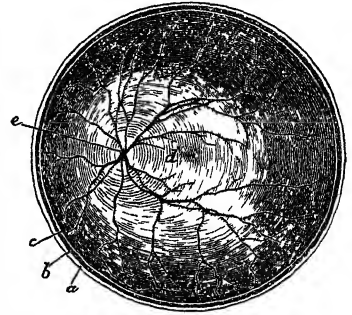

Fig. 4.—Posterior half of left Eye from the front :

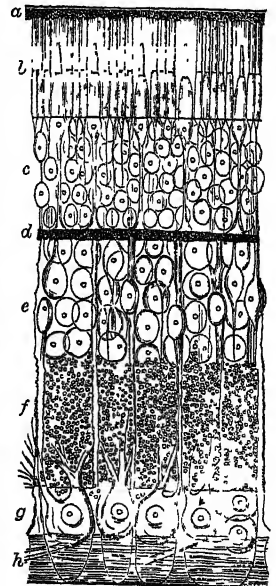

Fig. 5.—Diagrammatic Section of Human Retina.

The layer of rods and cones, the portion of the eye which receives the impressions of light, deserves special attention. The rods are thinner but longer than the cones, and in most parts of the retina far more numerous. At the yellow spot, however, only cones are found. Each rod or cone consists of a thicker inner portion, connected with the outer granular layer, and ultimately with the optic nerve by a fine fibril; and an outer thinner part, directed towards and connected with the pigmentary layer. The percipient elements are thus directed away from, not towards the light. 'In fact, we do not look outwards at the actual object, but we see the object as reflected from the base of our own eye.' Of the cones there are several, of the rods many millions in each human eye, and they are closely packed together over the whole extent of the retina.

It now remains for us to describe the *transparent media* which occupy the interior of the globe, and through which the rays of light must pass before they can reach the retina, and form on it the images of external objects. We shall consider them in the order in which the rays of light strike them.

Immediately behind the transparent cornea is the *aqueous humour*, which fills up the anterior and posterior chambers which lie between the cornea and the lens. As its name implies, it is very nearly pure water, with a mere trace of albumen and chloride of sodium. It is believed to be secreted by the choroid and to pass forward from it through minute lymphatic channels.

The *crystalline lens* lies opposite to and behind the pupil, in contact with the inner part of the iris, and its posterior surface is received into a corresponding depression on the forepart of the vitreous humour (see fig. 1). In form, it is a double-convex lens, with surfaces of unequal curvature, the posterior being the most convex. It is inclosed in a transparent capsule, of which the part covering the anterior surface is nearly four times thicker than that at the posterior aspect. The microscopic examination of the substance or body of the lens reveals a structure of wonderful beauty. Its whole mass is composed of extremely minute elongated ribbon-like structures, commonly called the *fibres of the lens*. These fibres are arranged side by side in lamellæ, of which many hundred exist in every lens, and which are so placed as to give to the anterior and posterior surfaces the appearance of a central star, with meridian lines. The lens gradually increases in density, and at the same time in refracting power, towards the centre; by this means, the refracting power is made greater than it would be even if the lens had throughout the same index of refraction as the nucleus. (According to the latest measurements, the index of refraction of the outer layer is 1.393; of the nucleus, 1.431; the total refractive power corresponds to that of a homogeneous body of the same size and shape with index 1.448.) This arrangement besides corrects to a certain extent the spherical aberration of the eye. According to Berzelius, the lens contains 58 per cent. of water, 36 of albumen, with minute quantities of salts, membrane, &c. In consequence of the albumen, it becomes hard and opaque on boiling, as we familiarly see in the case of the eyes of boiled fish. In the adult, its diameter transversely is about $\frac{1}{4}$ in., and its thickness antero-posteriorly about $\frac{1}{16}$ of an inch; and it weighs three or four grains. The lens is held in position by the *suspensory ligament* of the lens and *zonule of Zinn*, a fine transparent fibrous structure, attached outwardly to the choroid between the ciliary processes, and passing inwards to blend with the anterior and posterior capsule of the lens near its margin (see fig. 1).

The *vitreous humour* lies in the concavity of the retina, and occupies about four-fifths of the eye posteriorly. Its form is shown in fig. 1. It is inclosed, except in front, in the hyaloid membrane, which blends anteriorly with the zonule of Zinn; and its anterior surface is in contact with the posterior capsule of the lens. It is quite transparent, and of a soft gelatinous consistence. Its outer part at least is laminated, like the coats of an onion. But the exact arrangement of the framework which gives it its consistence has not been determined. Between the anterior border of the retina and the border of the lens, we have a series of radiating folds or plaitings termed the *ciliary processes of the vitreous body*, into which the *ciliary processes of the choroid* dovetail. The vitreous humour contains, according to Berzelius, 98.4 per cent. of water with a trace of albumen and salts, and hence, as might be expected, its refractive index is almost identical with that of water.

The appendages of the eye now claim our notice. The most important of these appendages are the *muscles within the orbit*, the *eyelids*, the *lacrimal apparatus*, and the *conjunctiva*, to which (although less important) we may add the *eyebrows*.

The *muscles* by which the eye is moved are four straight (or *recti*) muscles, and two oblique (the superior and inferior). The former arise from the margin of the optic foramen at the apex of the orbit, and are inserted into the sclerotic near the cornea, above, below, and on either side. The superior oblique arises with the straight muscles; but after running to the upper edge of the orbit, has its

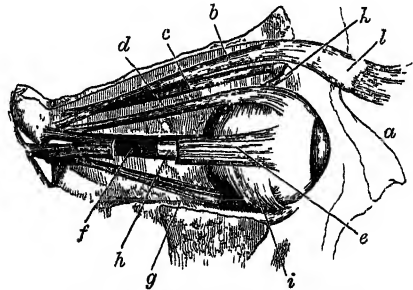

Fig. 6.—Muscles of Right Eyeball:

The external rectus muscle divided to show the optic nerve, which has also been cut to show the internal rectus muscle.

a, nasal bone; b, levator palpebrae superioris; c, superior oblique; d, superior rectus; e, external rectus; f, internal rectus; g, inferior rectus; h, optic nerve; i, inferior oblique; k, pulley; l, tarsal cartilage.

direction changed by a pulley, and proceeds backwards, outwards, and downwards (see fig. 6). The inferior oblique arises from the lower part of the orbit, and passes backwards, outwards, and upwards. The action of the straight muscles is sufficiently obvious from their direction: when acting collectively, they fix and retract the eye; and when acting singly, they turn it towards their respective sides. The oblique muscles antagonise the recti, and draw the eye forwards; the superior, acting above, directs the front of the eye downwards and outwards, and the inferior upwards and inwards. By the duly associated action of these muscles, the eye is enabled to move (within definite limits) in every direction.

The *eyelids* are two thin movable folds placed in front of the eye, to shield it from too strong light, and to protect its anterior surface. They are composed of (1) skin, with a layer of muscle (part of the *orbicularis*, see below) closely adherent to it; (2) of a thin plate of fibro-cartilage, termed

the *tarsal cartilage*, the inner surface of which is grooved by thirty or forty parallel vertical lines, in which the Meibomian glands are imbedded; and (3) of a layer of mucous membrane (*conjunctiva*), continuous, as we shall presently see, with that which lines the nostrils, and joining the skin at the margin of the lids, in which the eyelashes (*cilia*) are arranged in two or more rows. The upper lid is much the larger; and to the posterior border of its cartilage a special muscle is attached, termed the *levator palpebræ superioris*, whose object is to elevate the lid, and thus open the eye; while there is another muscle, the *orbicularis palpebrarum*, which surrounds the orbit and eyelids, and by its contraction closes the eye. The Meibomian glands secrete a sebaceous matter,

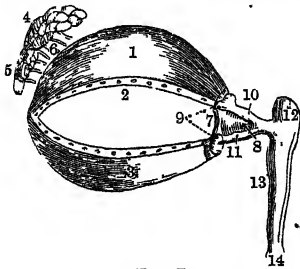

Fig 7.

The Appendages of the Eye :

- 1, the cartilage of the upper eyelid; 2, its lower border, showing the openings of the Meibomian glands; 3, the cartilage of the lower eyelid, also showing on its border the openings of the Meibomian glands; 4, 5, the lacrimal gland; 6, its ducts; 7, the plica semilunaris; 8, the caruncula lacrimalis; 9, the puncta lacrimalia, opening into the lacrimal canals; 10, 11, the superior and inferior lacrimal canals; 12, the lacrimal sac; 13, the nasal duct, terminating at 14 in the lower meatus of the nose

which facilitates the free motion of the lids, and prevents their adhesion. The eyelashes intercept the entrance of foreign particles directed against the eye, and assist in shading that organ from an excess of light.

The *lacrimal apparatus* consists of the lacrimal gland, by which the tears are secreted; two canals, into which the tears are received near the inner angle of the eye; the sac, into which these canals open; and the duct, through which the tears

pass from the sac into the nose. The gland is an oblong body, about the size of a small almond, lying in a depression in the upper and outer part of the orbit. The fluid secreted by it reaches the surface of the eye by twelve or fourteen ducts, which open on the conjunctiva at its upper and outer part. The constant motion of the upper eyelid induces a continuous gentle current of tears over the surface, which carry away any foreign particle that may have been deposited on it. The fluid then passes through two small openings, termed the *puncta lacrimalia* (see 9 in fig. 7), into the canals; whence its further course into the lower portion of the nose is sufficiently obvious from the figure. The conjunctiva (or mucous coat) which covers the front of the eyeball, and lines the inner surface of the lids, passes down and lines the canals, sac, and duct; and is thus seen to be continuous with the nasal mucous membrane, of which it may be regarded as an offshoot or digital prolongation.

We shall conclude this sketch of the anatomy of the human eye by a brief notice of the *nerves* going to this organ and its appendages. Into each orbit there enters a nerve of *special sense*—viz. the optic nerve; a nerve of *ordinary sensation*—viz. the ophthalmic branch of the fifth nerve; and certain nerves of *motion* going to the muscular tissues, and regulating the movements of the various parts—viz. the third, fourth, and sixth nerves.

As the optic tracts from which the *optic nerves* originate are noticed in the article *BRAIN*, we shall merely trace these nerves from their *chiasma* or *commissure* forwards. This commissure results

from the junction of the optic tracts of the two sides; and it is especially remarkable for the fact that it presents a partial decussation of the nervous fibres; the central fibres of each tract passing into the nerve of the *opposite* side, and crossing the corresponding fibres of the other tract, while the outermost fibres, which are much fewer in number than the central ones, pass to the optic nerve of the *same* side. In front of the commissure, the nerves enter the optic foramen at the apex of the orbit, receive a sheath or investment from the *dura mater*, acquire increased firmness, and finally terminate in the retina. The peculiar mode of termination of the optic nerves in the cuplike expansion of the retina, the impairment or loss of vision which follows any morbid affection of them, and the constant relation in size which is observed in comparative anatomy between them and the organs of vision, afford sufficient evidence that they are the proper conductors of visual impressions to the sensorium.

The first or ophthalmic division of the fifth or trifacial nerve sends branches to the eyeball (ciliary nerves), to the skin of the eyelids, and to the conjunctiva. That it is the nerve of ordinary sensation of the eye is sufficiently obvious from the following facts: (1) That in disease of this nerve in the human subject, it is not uncommon to find the surface of the eyeball totally insensible to every kind of stimulus (particles of dust, pungent vapours, &c.); and (2) that if the nerve be divided in the cranium (in one of the lower animals), similar insensibility results.

The most important of the nerves of motion of the eye is the third nerve, or *motor oculi*. It supplies with motor power the elevator of the upper eyelid, and all the muscles of the globe, except the superior oblique and the external straight muscle, and, in addition to this, it sends filaments to the iris and ciliary muscle within the eye. The application of an irritant (in vivisection experiments) to its trunk induces convulsive contraction of the principal muscles of the ball and of the iris; while paralysis or division of the trunk occasions an external squint, with palsy of the upper eyelid and fixed dilatation of the pupil. The squint is caused by the action of the external straight and the superior oblique muscles, while the other muscles are paralysed by the operation. The normal motor action of the nerve upon the iris, in causing contraction of the pupil, is excited through the optic nerve, and affords a good illustration of *Reflex Action* (q.v.); the stimulus of light falling upon the retina, and, through it, exciting that portion of the brain from which the third nerve takes its origin. This nerve clearly exerts a double influence in relation to vision: (1) it mainly controls the movements of the eyeball and the upper eyelid; and (2) from its connection with the muscular structures in the interior, it regulates the amount of light that can enter the pupil, and the adjustment of the eye to various distances. The fourth nerve supplies the superior oblique muscle with motor power, while the sixth nerve similarly regulates the movements of the external straight muscle—the only two muscles in the orbit which are not supplied by the third pair. Although not entitled to be termed a nerve of the orbit, the facial nerve deserves mention as sending a motor branch to the *orbicularis* muscle, by which the eyelids are closed.

(2) *Comparative Anatomy of the Eye.*—In mammals, the structure of the eye is usually almost identical with that of man. The organ is, however, occasionally modified, so as to meet the peculiar wants of the animal. Thus, in the Cetacea, and in some amphibious Carnivora that catch their prey in the water, the shape of the lens

is nearly spherical, as in fishes, and there is a similar thickening of the posterior part of the sclerotic, so as to thrust the retina sufficiently forward to receive the image formed by such a lens. (See the subsequent remarks on the eyes of fishes.) Again, instead of the dark-brown or black pigment which lines the human choroid, a pigment of a brilliant metallic lustre is secreted in many of the mammalia, forming the so-called *tapetum lucidum* at the bottom of the eyeball, which seems (according to Bowman) to act as a concave reflector, causing the rays of light to traverse the retina a second time, and thus probably increasing the visual power, particularly where only a feeble light is admitted to the eye. The pupil, moreover, varies in form, being transversely oblong in the Ruminants and many other Herbivora, and vertically oblong in the smaller genera of Cats. These shapes are apparently connected with the positions in which the different animals look for their food. Lastly, in some mammals (e.g. the horse) there is a rudimentary third eyelid corresponding to the *membrana nictitans* of birds.

In birds, the eye, though presenting the same general composition as in man, differs from the mammalian eye in several important points. From our knowledge of the habits of birds (especially birds of prey), we should naturally expect that in their rapid movements they would be able readily to alter the focus between the extremes of long and short sighted vision, and the modifications we shall now proceed to notice clearly have this object in view.

In reference to fig. 8, which represents a section of the eye of the owl, we see (1) that the shape of the organ is not spherical, as in mammals, nor flattened anteriorly, as in fishes and aquatic reptiles, but that the cornea is very prominent, and the antero-posterior diameter lengthened; the consequence of this arrangement being

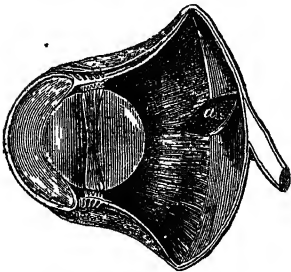

Fig. 8.—Eye of Bird.

to allow room for a large quantity of aqueous humour, and to increase the distance between the lens and the posterior part of the retina, and thus to produce a greater convergence of the rays of light, by which the animal is enabled to discern near objects. In order to retain this elongated form, we find a series of bony plates, forming a broad zone, extending backwards from the margin of the cornea, and lying imbedded in the sclerotic. The edges of the pieces forming this bony zone overlap each other, and are slightly movable, and hence, when they are compressed by the action of the muscles of the ball, there is protrusion of the aqueous humour and of the cornea, adapting the eye for near vision; while relaxation of the muscles induces a corresponding recession of the humour and flattening of the cornea, and fits the eye for distant vision. The focal distance is further regulated by a highly vascular organ called the *marsupium*, or *pecten*, which is lodged in the posterior part of the vitreous humour (fig. 8, a). It is attached to the optic nerve at the point where it expands into the retina, and seems to be endowed with a power of dilatation and contraction; as it enlarges, from distension of its blood-vessels, it causes the vitreous humour to push the lens forwards, while, as it collapses, the lens falls backwards again towards the retina.

In addition to an upper and lower eyelid, birds have an elastic fold of conjunctiva, which, in a state of repose, lies in the inner angle of the eye, but is movable by two distinct muscles, which draw it over the cornea. It is termed the *membrana nictitans*; it is to a certain degree transparent, for (according to Cuvier) birds sometimes look through it, as, for example, the eagle when looking at the sun. The lachrymal gland is situated as in mammals, but there is here a second gland, the *glandula Harderi*, which yields a lubricating secretion.

There are no very special peculiarities in the eyes of reptiles, and we therefore proceed to notice the most remarkable points presented by the eye in fishes. From the comparatively great density of the medium (water) through which the rays of light pass before they impinge upon the transparent structure of the eye of the fish, it is obvious that this organ must act as a very powerful refractive apparatus. The main peculiarity in the eye of the fish is the size, extreme dens-

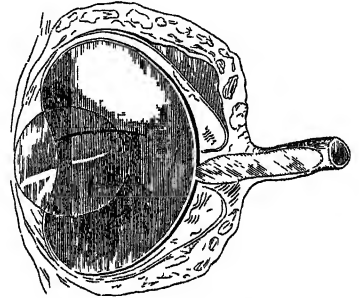

Fig. 9.—Eye of Fish.

ity, and spherical shape of the lens, which give it such an extraordinary magnifying power that it has been employed as a simple microscope. See Brewster's *Treatise on the Microscope*, p. 31. But its focus being shortened in proportion as its power is increased, it is necessary that the retina should be brought near its posterior surface. For this purpose the eyeball is flattened by diminishing the quantity of vitreous humour; and this flattened form is maintained by the existence of two cartilaginous plates in the tissue of the sclerotic, which in some of the larger fishes is actually converted into a bony cup. The aqueous humour, as the cornea has here hardly any refractive power and is also flattened, is barely sufficient to allow the free suspension of the iris. The pupil is very large, so as to take in as much light as possible, but is generally motionless. Their eyes being constantly washed by the water in which they live, no lachrymal apparatus is necessary, nor does any exist; and the same remark applies to the *cetacea* amongst the mammals. We thus see that throughout the sub-kingdom of the *vertebrata* the eye is constructed according to one general scheme, with modifications to suit the mode of life of individual classes.

There is another organ present in most vertebrate animals which seems, from recent investigations, to represent an eye, though it is very doubtful whether it has the power of sight in any living animal. This is represented in mammals and birds by the pineal gland (see BRAIN); but in some lizards is placed upon the top of the head, and has the appearance of a rudimentary eye, similar in structure to that of some of the Invertebrata.

In the Invertebrata there is an immense variety in the structure of the eye where such an organ is present. There are two main types, *simple* and *compound* eyes. In *simple* eyes (of which the human eye itself is the most highly organised form), every degree of complexity is present, from a mere pigmented spot, with or without a rudimentary lens, to an organ nearly as complicated as that of the Vertebrata (e.g. in some of the Cuttle-fishes), with a cornea, iris, lens, and retina all well

developed. In these eyes, however, almost without exception, the nerve expands behind the retina, and the percipient elements are directed towards the light; while in the vertebrate eye the opposite arrangement obtains.

Some of these organs are so rudimentary that they can have no function beyond mere perception of light; but in cases where they are sufficiently developed to admit of the perception of objects, they see, roughly speaking, as our eyes do—that is to say, a more or less accurate picture of external objects is thrown on the expansion of nerve-endings corresponding to the retina, and its direction is reversed (see below).

In the compound eyes the whole principle of the structure and perception is different. They are best developed in Insects (q.v.), and in the higher Crustaceans; but occur in a rudimentary condition in some molluscs. The surface of such an eye is divided into a number of hexagonal facets, the cuticle of each generally forming a minute lens. Beneath each facet is a transparent rod, surrounded and separated from those adjacent to it by pigment, and leading inwards to the retinula, a group of cells in connection with the terminal fibrils of the optic nerve. In most familiar insects they form two hemispherical masses on the sides of the head. In some ants there are only fifty facets in each eye; in the house-fly about 4000; in some beetles as many as 25,000. It is probable that in these eyes only the rays of light which fall upon a particular facet exactly, or very nearly, in the direction of the transparent rod beneath it can reach the corresponding nerve-fibre, and that other rays are absorbed by the pigment around the rod. Each percipient element therefore receives light only from a very small portion of the field of vision, and the picture is a mosaic, each element of which is furnished by a different facet of the eye. The picture has obviously the same position as the objects it represents, instead of being inverted as in a simple eye. Most insects have simple as well as compound eyes; but the latter have by far the most perfect vision.

(3) We may now proceed to the consideration of the uses of the various parts of the eye. Assuming a general knowledge of the ordinary laws of geometrical optics (see OPTICS, LENSES, &c.), we shall trace the course of the rays of light proceeding from any luminous body through the different media on which they impinge. If a luminous object, as, for example, a lighted candle, be placed in front of the eye, some of its rays fall upon the cornea, and are in part reflected, giving to the surface of the eye its beautiful glistening appearance; in part refracted or converged by it, to enter the aqueous humour, which exerts no perceptible effect on their direction. Those which fall on and pass through the outer or circumferential part of the cornea are stopped by the iris, and are either scattered or absorbed by it; while those which fall upon its more central part pass through the pupil, and are concerned in vision. In consequence of its refractive power, the rays passing through a somewhat larger surface of the cornea than the pupil are converged so as to pass through it and impinge upon the lens, which, as its refractive index is much greater than that of the aqueous and vitreous humours, by the convexity of both its surfaces very much increases the convergence of the rays passing through it. They then traverse the vitreous humour, whose principal use appears to be to afford support to the expanded retina, and are brought to a focus upon that tunic, forming there, if the eye be adjusted for the distance from which the rays proceed, an exact but inverted image of the object.

This inversion of the image may be easily exhibited in the eye of a white rabbit or other albino animal, after removing the muscles, &c. from the

back part of the globe. The flame of a candle (A, B, C, fig. 10) held before the cornea may be seen inverted at the back of the eye (*a*, *b*, *c*), increasing in size as the candle is brought near, diminishing as it retires, and always moving in a direction opposite to that of the flame.

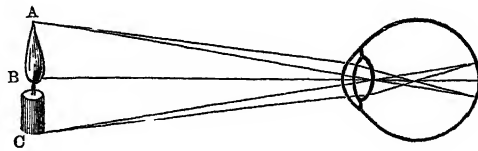

Fig. 10

The adjustment of the eye for distinct vision at different distances, or *accommodation*, must next be considered. The normal eye in the position of rest is adjusted to see objects at a distance (practically all objects at 20 feet or more are seen with equal clearness): to see a near object (at 10 inches, say) a distinct effort is required, and when the effort ceases the object at once appears blurred. Careful observations and measurements by means of a suitable instrument (Ophthalmometer) of images reflected from the three principal refracting surfaces of the eye (cornea, anterior and posterior surfaces of crystalline lens) have shown that during

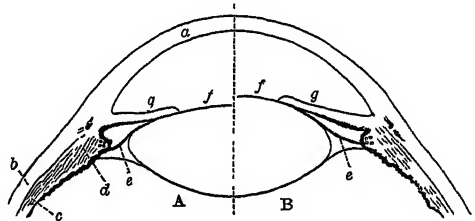

Fig. 11.—Action of Ciliary Muscle and Iris in accommodation:

A, (right or left) half; eye at rest, or focused for a distant object. B, (left or right) half; eye focused for a near object. *a*, cornea; *b*, sclerotic; *c*, anterior part of choroid; *d*, ciliary muscle; *e*, suspensory ligament of lens; *f*, anterior capsule of lens; *g*, iris.

accommodation for a near object (1) the position and curvature of the cornea remains unchanged; (2) the anterior surface of the crystalline lens approaches the cornea and becomes much more convex; (3) the posterior surface does not change its position, but becomes very slightly more convex. Accommodation, then, depends upon change of shape of the crystalline lens. The common explanation of the mechanism by which this is effected was first given by Helmholtz. The ciliary muscle, as already stated, has its fixed attachment all round within the sclerotic close to the margin of the cornea; and passes outwards and backwards to the anterior part of the choroid, close to the ciliary processes. When it contracts, therefore, it draws these structures inward; and with them the outer attachment of the suspensory ligament of the lens. The tension of this membrane is thus relaxed, and the elastic lens, whose form as well as position is controlled by it, is allowed to assume a more spherical shape. When the ciliary muscle ceases to contract, the converse takes place, and the lens is again flattened as the suspensory ligament and lens capsule become more tense. With the contraction of the ciliary muscle is always associated a contraction of the circular fibres of the iris, diminishing the size of the pupil; and when the ciliary muscle relaxes, the pupil enlarges again. This

change, though of much less importance than the change in shape of the lens, is much more easy to observe.

Change of adjustment requires a short but measurable time; that from distant to near vision requires a little longer time than the converse; the former from a little over one to two seconds, the latter about one second.

As age advances, the power of accommodation steadily and quickly diminishes, not because the ciliary muscle gets weaker, but because the lens becomes less elastic. This change begins during youth, but is not commonly noticed before middle life. At ten years of age an object can be seen distinctly at less than 3 inches; at twenty, not nearer than 4 inches; at about forty-five, not nearer than 10 inches; at sixty, not nearer than 3 feet. After seventy-five, the lens is so unyielding that accommodation is altogether lost. When the shortest distance at which distinct vision is possible approaches that at which reading or work is usually attempted, the failure of accommodation begins to attract attention, and spectacles have to be resorted to to compensate for it. This condition has received the name of *presbyopia* or old sight, but must be clearly understood to be perfectly natural after the age of forty-five, and in no way to imply defect or weakness of the eyes.

The eye, regarded as an optical instrument, has numerous imperfections: the more important of these must be mentioned.

Spherical aberration (see LENSES) is in part avoided by the iris, which, acting as a diaphragm, cuts off all but the central pencil of rays; in part by the forms of the refracting surfaces, which are not truly spherical, but ellipsoidal or hyperbolic — i.e. more curved at the centre than elsewhere; in part by the constitution of the lens (see above). What remains is, like *chromatic aberration*, for which no correction seems to exist, too slight to be perceptible.

Regular *Astigmatism* (q.v.) is present in almost all eyes, but is generally so small in amount as to be of no importance.

Imperfect Transparency of Media.—The stellate arrangement of the lamellæ of the lens is the cause of the rayed (or, as we say, star-shaped) appearance of a point of light. *Musce volitantes*, the clear threads or strings of beads often seen in looking at a bright surface flitting about when the eye is moved, are due to the shadows of the minute fibres and corpuscles naturally present in the vitreous humour.

(4) We must now consider how the image formed in the back of the eye by the dioptric media gives rise to vision. It is the retina, and only that part of it known as the layer of rods and cones (see fig. 5), which is directly affected by light.

Let two marks be made on a sheet of paper about 3 inches apart horizontally (a cross and a round mark to the right of it). Close the left eye, and holding the paper about a foot from the face, look steadily at the cross; the circle is also visible. Now bring the paper gradually nearer, keeping the right eye fixed upon the cross. The circle soon disappears; but becomes visible again when the paper is brought still nearer the eye. The *blind spot* in which the circle becomes invisible is the entrance of the optic nerve; hence we know that the nerve-fibres themselves are not sensitive to light. Further proof of this is given by *Purkinje's figure*, which is easily perceived as follows: Take a candle in a room otherwise dark, and holding it a short distance in front and to the outer side of one eye, move it from side to side, looking straight forward. A set of branching dark lines, the shadows of the retinal blood-vessels, will be seen (see fig. 4). These could not be perceived unless the sensitive

portion of the retina lay behind the blood-vessels, which the nerve-fibre layer of the retina does not.

Stimulation of the retina, however it may be caused, gives rise to the sensation of light. Thus, slight pressure on one side of the eyeball causes an appearance of flashes of light towards the opposite side. A sudden blow on the eye, or the indirect shock to it of a fall on the head, makes one 'see stars.' Electric currents passed through the eye similarly cause a sensation of bright light. But true vision is only caused by rays of light falling upon the retina.

In what way light affects the layer of rods and cones we do not know. Probably it produces some chemical change, which leads to stimulation of the nervous elements. A substance called *visual purple* or *rhodopsin* has been found in the outer segments of the rods of some animals, which is bleached on exposure to light, and regenerated. Photographic pictures of bright objects have been obtained in eyes of rabbits, &c. by means of it. Rods are absent in the most sensitive portion of the human retina, but the visual purple diffuses into the surrounding liquid.

The *fovea centralis* is the part of the retina where vision is most acute: as cones only are present here, it is probable that from them alone the impulse passes along the nerve, and not from the rods, which greatly preponderate at other parts of the retina. When the eye looks straight at an object (or in technical language *fixes* it), its image falls upon this part of the retina. In *direct* vision, as this is called, two black marks on a white ground are distinguished as separate when the interval between them subtends an angle of about one minute at the eye. It is found by calculation that this angle, prolonged to the back of the eye, pretty nearly corresponds to the distance between two adjacent cones at the fovea centralis. The vision at other parts of the retina (*indirect* vision) is very much less acute, and less capable of accurate measurement. We have only to fix steadily one letter in a page of ordinary print to satisfy ourselves in how small an area we can see sufficiently distinctly to make out words without moving the eyes. The *field of vision*, or whole space within which objects are perceived by an eye while it is fixed upon one point, is very much wider, extending in each eye to more than 90 degrees from the fixation point or centre to the outer side, and rather less in other directions. Colour-vision is also most distinct at the centre of the field; and it diminishes more rapidly towards the outer portions than light-vision, so that near the limits of the field colours cannot always be recognised. See COLOUR-PERCEPTION, COLOUR-BLINDNESS.

There must be a certain amount of light for the purpose of vision. Every one knows that it is difficult and painful to discern objects in a very faint light; and, on the other hand, that on suddenly entering a brilliantly lighted room from the dark, everything appears confused for one or two seconds. There is, however, a gradual adaptation of the retina to different amounts of light. Persons long immured in dark dungeons acquire the power of distinctly seeing surrounding objects; while those who suddenly encounter a strong light are unable to see distinctly until the shock which the retina has experienced has subsided, and the iris has duly contracted. In protecting the retina from the sudden effects of too strong a light, the iris is assisted by the eyelids, the orbicular muscle, and to a certain extent by the eyebrows. Moreover, the dark pigment of the choroid coat acts as a permanent guard to the retina, and where it is deficient, as in albinos, an ordinary light becomes painful, and the protective appendages, especially the eyelids, are in constant use.

The persistence during a certain time of impressions made on the retina facilitates the exercise of sight. Such persistent impressions are called *after-images*. A momentary impression of moderate intensity continues for a fraction of a second; but if the impression be made for a considerable time, or be very intense, it endures for a longer period after the removal of the object. Thus, a burning stick, moved rapidly in a circle before the eyes, gives the appearance of a continuous ribbon of light, because the impression made by it at any one point of its course remains on the retina until it again reaches that point. It is owing to this property that the rapid and involuntary act of winking does not interfere with the continuous vision of surrounding objects; and, to give another illustration of its use, if we did not possess it, the act of reading would be a far more difficult performance than it now is, for we should require to keep the eye fixed on each word for a longer period, otherwise the mind would fail fully to perceive it. However great may be the velocity of a luminous body, it can always be seen; but if an opaque body move with such rapidity as to pass through a space equal to its own diameter in a less time than that of the duration of the retinal impression, it is altogether invisible; and hence it is, for example, that we cannot see bullets, &c. in the rapid part of their flight. In these cases the after-image is of similar brightness and colour to the original impression, and is known as a *positive* after-image. When the stimulation of the retina is very strong, or the retina itself in a very sensitive condition—e.g. in certain morbid states of the system and in twilight, a *negative* after-image appears, in which the bright parts of the original impression appear dark and *vice versa*. An image of this kind may persist for some seconds or minutes or even longer. This physiological phenomenon has probably given origin to many stories of ghosts and visions. Thus, if a person has unconsciously fixed his eyes, especially in the dusk, on a dark post or stump of a tree, he may, on looking towards the gray sky, see projected there a gigantic white image of the object, which may readily be mistaken for a supernatural appearance. The phenomenon is easily seen on looking away from a bright window after directing the eyes to it for some time, when the bars appear as bright lines on a dark ground. Negative after-images are always of the complementary colour to that of the object. Thus, the image left by a red spot is green; by a violet spot, yellow; and by a blue spot, orange.

(5) Each eye can be moved from its ordinary position, looking straight forward, through an angle of nearly 60 degrees downwards, and of 35 to 45 degrees in other directions. But one eye never moves without the other. Two series of associated movements have to be distinguished: movements of both eyes in the same direction, and movements which *converge* the eyes, or bring the corneæ of both eyes towards each other. When a near object is looked at, the movement of accommodation is associated with a proportionate contraction of the internal recti of both eyes, so as to direct the visual axis, or in other words the fovea centralis, of each towards the object.

If we suppose the retinæ of the two eyes to be placed in contact, so that the foveæ centrales and the vertical meridians correspond, then all points which lie together in the two retinæ are called *corresponding points*, and have the property that simultaneous stimulation of both gives rise only to a single impression. An object whose image falls upon corresponding points thus appears single; otherwise it appears double. Hold up two

fingers in line in front of the face. When the nearer one is looked at, it is seen single, but the farther appears double and somewhat out of focus; when the farther is looked at, it appears single, and the nearer is similarly doubled and blurred. Generally speaking, images of the great majority of the objects in the field of vision of both eyes must fall on non-corresponding points of the two retinæ; but as the attention is generally directed to the images of the object for which the eyes are accommodated, and as these, falling upon the foveæ centrales, are much the most distinct, the double vision of other objects is seldom noticed.

In the case of near objects, however, something more is needed to explain single vision. For example, take the case of a solid object. The two eyes, looking from different points of view, receive quite different images; the right eye sees more of the right side, the left eye more of the left. It is impossible that the images of each point of the object can fall upon accurately corresponding points of the two retinæ. Yet the appearance presented is that of a single object clearly defined. In this case then there must be in the brain-centres a power of combining in a single picture images which do not accurately correspond.

Various topics which the reader might perhaps have expected to find noticed, such, for instance, as 'the appreciation of solid forms by the sense of vision,' 'correct vision with an inverted image on the retina,' &c., which belong fully as much to metaphysics as to physiology, are discussed in the article on VISION. We may also refer those who desire information on these points to Professor Bain's treatise on *The Senses and the Intellect*.

For the anatomy of the eye, see Quain or other standard work. Aveybury in *The Senses of Animals* gives a concise account of the chief types of eyes in the Invertebrata. Helmholtz's *Physiological Optics* is the classical work on the optical aspects of the eye. The larger works on human physiology—e.g. Foster, Landois and Stirling—may also be consulted.

DISEASES AND INJURIES OF THE EYE, as might be expected from the delicate and complicated structure of the organ, are very numerous. But as the position of the eye and the transparency of its dioptric media give exceptional facilities for their detection and study, they are more thoroughly understood than those of any other organ. Only the most common and important can be referred to here.

Diseases of Conjunctiva are mainly different forms of inflammation, or *conjunctivitis*.

(a) *Simple or Catarrhal Conjunctivitis* may be acute or chronic. In the former case, it is commonly called 'cold in the eye.' The white of the eye is more or less reddened, and there is an increased discharge of gummy substance, causing the lids to cohere during sleep; a sensation is experienced as of sand or dust in the eyes, and there is a little increased sensitiveness to light. The acute form generally subsides in a few days without leaving any ill effects, unless improperly treated; the chronic form is often obstinate. The common popular treatment—viz. tying wet cloths or poultices over the eye, cannot be too strongly condemned; it may produce temporary relief of irritation, but aggravates the inflammation, and is very apt to lead to ulceration of the cornea. A mild astringent lotion should be used thrice or oftener in the day (boracic acid 10 grains, alum 3 grains, to the ounce of water); and a little simple ointment, e.g. boracic ointment, applied to the lids at bedtime to prevent their becoming glued together. The chronic form often requires stronger remedies, but they should not be used except under medical advice.

(b) *Purulent Conjunctivitis* resembles the last, but is very much more severe, and highly dangerous. In its most characteristic forms it is known as *gonorrhoeal ophthalmia*, and *ophthalmia neonatorum* (eye inflammation of new-born children). To the latter variety about one-third of the blind persons in Europe owe their loss of sight. It is caused by infection of the infant's eye with gonorrhoeal discharge at birth; and the discharge from an affected eye will infect any other eye with which it comes in contact. The conjunctiva becomes intensely red and swollen, and the lids partake in the swelling so that they cannot be opened; there is severe burning pain, and after two days or more a profuse discharge of matter. The danger to sight is due to the fact that the cornea is extremely apt to be destroyed, wholly or in part, before the inflammation subsides. In infants the disease usually begins on the third day after birth, and is, as a rule, less severe than in the adult, but unfortunately is often overlooked, or regarded as of no importance till irreparable mischief has been done. Scrupulous cleansing of the eyes immediately after birth, and dropping in of a 2 per cent. nitrate of silver or of corrosive sublimate lotion (1 grain to 8 ounces) is the best preventive. When the disease has commenced, very frequent removal of discharge and washing with a similar lotion is necessary. But all such cases should at once be put under the charge of a medical man.

(c) *Pustular or Phlyctenular Conjunctivitis* is a form of inflammation very frequent in children, much less so in adults. It is an indication of a lowered state of the general health, and its treatment must include fresh air and light, good food, and cod-liver oil or some other strengthening medicine. The inflammation does not extend all over the white of the eye, but is localised in one or more sections of it, and is most intense near the margin of the cornea, where one or more small rounded blebs or pimples may be seen. It is often accompanied in children by extreme tenderness to light; but the tendency to this is aggravated by a bandage or darkness. The local treatment should be bathing with boracic acid or some other mild astringent lotion; but, unless the case be very mild, a medical man should be consulted.

(d) *Granular Conjunctivitis*, or *trachoma*, is an exceedingly chronic and intractable disease. It is sometimes called Egyptian ophthalmia, having been extremely prevalent in the French army in Egypt in 1798. In Europe it is most common among the Jews and the Irish, but is often troublesome in industrial schools and similar institutions. It is encouraged by overcrowding, bad ventilation, and other unfavourable hygienic conditions, and is undoubtedly somewhat contagious. It is characterised by numerous distinct semi-transparent elevations on the conjunctiva of the lids, chiefly the upper. It often lasts for months or years, and is chiefly dangerous on account of the shrinking of the conjunctiva produced by it, which leads to trichiasis, Ectropion (q.v.), and opacity of the cornea. It should always be treated by a skilled medical man.

(e) In *Diphtheritic Conjunctivitis* there is a 'false membrane' formed on the conjunctiva, as in Diphtheria (q.v.) in other situations. It is happily rare in Britain.

Diseases of the Cornea.—The most common and important are inflammations associated with ulceration—i.e. destruction of some of the corneal substance. This is replaced when healing takes place by imperfectly transparent tissue, and results very frequently in great impairment of vision (irregular Astigmatism, q.v.), even where no obvious mark remains. The appearances, symptoms, and appro-

priate treatment of different forms and stages of corneal ulceration are extremely various, and cannot profitably be discussed here. Skilled medical advice should always be obtained. It must suffice to say that the eyes should be rested, shaded from light, and bathed, generally with boracic or corrosive sublimate lotion. Poulticing or tying up the eyes should never be resorted to unless under a doctor's orders, as it is usually still more mischievous than in conjunctivitis.

In one form of inflammation of the cornea, called *interstitial*, there is an appearance all over it of great haziness or even complete opacity, but without breach of surface. It occurs usually in boyhood or girlhood, and though alarming in appearance and tedious, generally results in complete recovery. Mr Jonathan Hutchinson first pointed out that it is usually a manifestation of congenital syphilis.

The *sclerotic* is comparatively seldom affected by disease, probably on account of its slight vascularity and comparatively low vitality.

The *iris* is liable to inflammation (*iritis*), characterised by severe deep-seated pain, redness of the white of the eye, contracted pupil, and much dimness of sight. The inflammation, if unchecked, produces adhesion between the posterior surface of the iris and the anterior capsule of the lens, which may permanently interfere with vision, or even lead ultimately to complete loss of sight. Local treatment at the early stage by Atropia (q.v.) dilates the pupil and prevents the formation of adhesions. Unless the result of injury, iritis usually depends on constitutional causes, especially syphilis and rheumatism, and treatment of these is of prime importance for its cure. Medical aid should be sought at once; for atropia, which is most beneficial in iritis, is disastrous in glaucoma, a disease which sometimes resembles it in many of its symptoms.

The chief disease of the *lens* is opacity, or Cataract (q.v.); it may also be displaced or dislocated, either from an anomaly in its development, or as the result of injury.

Diseases of the deeper structures of the eye (choroid, vitreous humour, retina and optic nerve) usually require for their recognition the use of the Ophthalmoscope (q.v.). Generally speaking, they are associated with little or no pain, and attract the patient's attention in consequence of the dimness of vision they produce. They are much less amenable to treatment in most cases than affections of the more superficial parts.

Inflammation and atrophy of the *choroid* occur in several forms; the most distinct are those occurring in syphilis, in old age, and in connection with high degrees of short-sightedness (progressive myopia, see below).

The *vitreous humour* rarely if ever becomes diseased, except in consequence of changes in the ciliary body or choroid. The abnormal condition generally manifests itself in more or less opaque threads or films, which move with the movements of the eye, and appear to the patient as clouds or dark lines interfering with vision, much more large and distinct than the 'muscae volitantes' present in the normal eye.

The *retina* may be the seat of hemorrhage or of inflammation in many forms of disease. The most common and characteristic retinitis is that associated with Bright's disease (q.v.), which is almost always of very serious import. Its main artery may become blocked by a plug carried into it from the heart or elsewhere (*Embolism*; see ARTERIES, DISEASES OF), an accident which causes sudden and usually almost complete loss of sight. Not unfrequently, too, the retina becomes detached from the choroid, either as the result of disease or injury, and floats in the

vitreous chamber in front of its normal position, a condition greatly interfering with sight, and most difficult to improve.

The *optic nerve* may become inflamed (*optic neuritis*), most commonly in consequence of an inflammation or tumour of the brain or its membranes. It may degenerate (*optic atrophy*) either after inflammation or independently of it. In the latter case, however, as well as the former, there is in the great majority of instances some disease of other parts of the nervous system (brain or spinal cord).

There are two diseases chiefly affecting the deeper parts of the eye which it is desirable to describe at some length, as their course is often insidious, and their results when not recognised early, most disastrous, while timely interference is often signally successful in preserving the sight. These are *glaucoma* and *sympathetic ophthalmia*.

Glaucoma occurs most commonly during or after middle life, frequently in persons whose eyes are hypermetropic (see below). It may come on with such suddenness and intensity that vision is lost in a few hours, or its course may extend over years. Always, however, if unchecked, it tends to progress till sight is destroyed. Both eyes are usually affected, but often one long before the other. In many cases there are *premonitory* symptoms, consisting in temporary attacks of cloudiness of vision, during which the patient, when looking at a light (e.g. a gas or candle flame), sees it surrounded by coloured rings or halos. During this 'premonitory stage,' the vision is perfectly normal between the attacks; but they become more frequent and prolonged, till it is permanently impaired. Variability of the symptoms is usually a characteristic feature in all stages of the disease. Often in the later phases, and always in acute and severe cases, much pain is experienced in and around the eye affected. The pupil is large and immobile; the iris and lens farther forward than normal; the cornea more or less hazy; and some of the blood-vessels of the white of the eye larger and more visible than they should be. The most important sign of the disease, and the feature on which many of its characteristics depend, is increased hardness of the eyeball, owing to increase of its contents. The exact cause of this increased hardness is not fully understood, nor the way in which some of the symptoms observed depend upon it; but it varies with the symptoms, being always more marked when the pain and dimness are at their worst. Chronic insidious cases are often mistaken for cataract, though the use of the ophthalmoscope readily distinguishes between the two conditions; in the most acute cases, the headache, sickness, and general disturbance of the system is sometimes so severe that the condition of the eyes is overlooked, and the disease is looked upon as a 'bilious attack' till the vision is hopelessly destroyed.

The disease was regarded as absolutely hopeless till Von Graefe, in 1857, proved that the removal by operation of a portion of the iris of a glaucomatous eye might arrest the process. This proceeding (*iridectomy*), though by no means uniformly successful, does good in the majority of cases, and has been of enormous benefit. But if too long delayed, it is of no avail for the restoration of vision.

It is of great importance that atropin or belladonna should not be applied to an eye with any tendency to glaucoma, as they aggravate the disease, and sometimes even produce it. Eserin, the active principle of the Calabar bean, has an action on the eye antagonistic to atropin, and can often keep glaucoma in check, though it rarely cures it. Pilocarpin, the active principle of *Jaborandi*, has a similar action.

Sympathetic Ophthalmia is the name given to a form of inflammation, chiefly of the iris and ciliary body, occurring in an eye previously healthy in consequence of disease or injury of the other. Almost, if not quite, invariably the eye first affected has had its coats (cornea or sclerotic) perforated; and the process in the second eye may begin at any time, from a fortnight to many years after this occurrence. It is an extremely insidious disease, sometimes quite painless; but also extremely dangerous, for it often leads to total loss of sight. The early symptoms are watering, tenderness to light, and dimness of sight, especially of near objects. When it begins, there is almost invariably irritability and tenderness to touch in the eye which is the origin of the disease. It can be absolutely prevented by early removal of the eye first affected; but if this be delayed till the inflammation has begun in the second eye, it may be useless. An eye which has received a perforating wound, particularly in the 'ciliary region'—i.e. just outside the cornea—may therefore at any subsequent period become a source of danger to the other eye; and if its vision is destroyed there can be no doubt that it should be removed. Even if some useful sight is retained, this may sometimes be desirable; but at all events, every one who has suffered from such an injury to one eye should know that the slightest symptoms of irritation or failure of sight in the other should at once lead him to seek skilled advice. Recent researches have rendered it probable that this form of inflammation is caused by micro-organisms, though this is not quite definitely established.

Errors of refraction are those defects in the dioptric media of the eye which, without diminishing their transparency, interfere with the formation of a retinal image in the normal way. Astigmatism (q.v.) has already been noticed; presbyopia is the failure of accommodation natural to age (see above). It remains to describe *myopia*, or short-sightedness, and *hypermetropia*, or long-sightedness. In most cases the condition of both eyes is alike, or nearly so; but exceptionally there is a considerable difference between them (*anisometropia*).

The knowledge of this branch of the subject was first systematised and placed on a satisfactory basis by Donders (1818-89), a distinguished Dutch physician and physiologist, professor of Physiology at Utrecht, in his work on *Anomalies of Accommodation and Refraction of the Eye* (Eng. trans. pub. by Sydenham Society, 1866).

The normal eye in the position of rest is adjusted for parallel rays—i.e. for a distant object, and by means of the accommodation can be focused for a near object. The short-sighted eye at rest is adjusted for divergent rays—i.e. for a near object; accommodation enables it to focus for a still nearer object, but it can make no change enabling it to see clearly beyond its 'far point'—i.e. that for which it is adjusted at rest. The long-sighted eye at

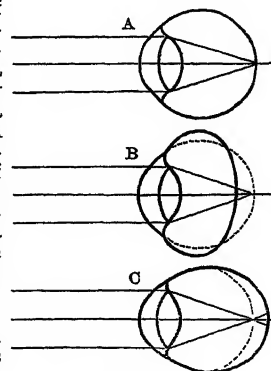

Fig. 12.

A, Normal eye: parallel rays brought to a focus at retina. B, Hypermetropic eye: globe shortened; parallel rays not yet brought to a focus when they reach retina. C, Myopic eye: globe lengthened; parallel rays brought to a focus in front of retina.

rest is adjusted for convergent rays, which do not occur in nature; accommodation enables it to focus parallel rays (from distant objects), or divergent rays (from near objects), but not to see so near as a normal eye of the same age.

These defects generally depend on an abnormality in the length of the antero-posterior diameter of the eyeball; in short-sighted eyes it is greater, in long-sighted less than the normal (see fig. 12). They can be corrected by the use of suitable glasses; in short-sighted eyes concave lenses are used, which render the rays of light falling upon them more divergent; in long-sighted eyes convex lenses, which render the rays less divergent or convergent.

Loss of accommodation occurs with the progress of years in such eyes, just as in normal ones, though the effects are somewhat different. The short-sighted eye continues to be able to see near at hand without spectacles; but, contrary to the popular belief, has no other advantage over the normal eye as age advances, for vision of distant objects does not improve. The long-sighted eye in time loses the power of seeing even distant objects without spectacles; and the higher the degree of long-sightedness the earlier the age at which this occurs.

An abnormal shape of the eye, on which these 'errors of refraction' usually depend, is frequently hereditary, and is incurable; it usually remains stationary after early adult life, but in some cases of myopia, where it is associated with disease of the choroid, tends to become worse (*progressive* or *malignant myopia*). The object of treatment must be to counteract, so far as possible, the inconvenience resulting; and this can generally be done by the use of spectacles or eyeglasses. No general rules can be laid down as to their use, as much depends not only on the degree of the abnormality, but on the age and occupation of the individual. If glasses conduce to comfort and to the preservation of the sight, no mere regard for appearance should prevent their being worn.

Diseases of the Eyelids.—A *stye* is practically a minute Boil (q.v.) formed in the eyelid, and discharging at its margin. It should be fomented frequently with hot water till it bursts. Constitutional treatment is often desirable, as styes often occur, like boils, in groups or series.

Small rounded swellings (*tarsal cysts*) often form under the skin of the lids, owing to obstruction of the duct of a Meibomian gland. They are usually painless, but require for their cure the evacuation of their contents through a puncture on the inner surface of the lid.

A form of Eczema (q.v.) often occurs at the margin of the lids, called *blepharitis*, most commonly in delicate children. It can usually be readily cured if attended to in time; but if neglected, as it too often is, leads to destruction (blear eyes) or misdirection (trichiasis) of the eyelashes, and much subsequent trouble. It is characterised by redness and ulceration of the edges of the lids, usually masked by crusts adhering to the lashes. Frequent removal of these, with the daily application of a stimulant ointment (e.g. yellow oxide of mercury, 8 grains to the ounce of simple ointment), and the use of tonics generally effect a cure. Inversion (Entropion, q.v.) and eversion (Ectropion, q.v.) of the margins of the lids, and misdirection of the eyelashes (trichiasis), so that they rub against and irritate the cornea, are troublesome affections, usually requiring operation for their removal.

Diseases of the Lachrymal Apparatus.—A 'watery eye' (*epiphora*), when no irritating affection of the eye itself is present, usually proceeds from stricture of the nasal duct, or some other cause, which prevents the tears from discharging by their natural channel into the nose. The condition can be remedied in most cases by *sitting up* the canalic-

ulus (see fig. 7), and passing graduated probes through the duct to restore its patency. If unattended to, it generally leads sooner or later to abscess of the lachrymal sac, with much swelling and pain.

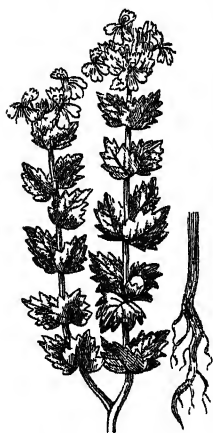

Injuries.—In no part of the body is there so often great disproportion between the severity of an injury and the amount of pain and irritation it occasions. A penetrating wound sometimes causes less discomfort than a mere particle of sand beneath the eyelid. Any wound or blow affecting the eye, therefore, particularly if it interfere at all with the sight, should be seen by a doctor as speedily as possible. Substances thrown against the eye may injure it. Quicklime is rapidly destructive to the eye, slaked lime and mortar less so. When one of these, or any other alkaline caustic, has got into the eye, diluted vinegar should at once be used to neutralise it. If it is oil of vitriol (sulphuric acid) or another acid that has been the cause of the injury, a weak solution of soda may be used in the first place to neutralise the acid. After this, sweet oil is the best thing to introduce, until the surgeon arrives. In gunpowder explosions near the eye, besides the burn, the particles are driven into the surface of it, and will cause permanent bluish stains over the white of the eye, unless they are carefully removed at the time. When chips of glass, stone, &c. are driven into the interior of the eye, there is little hope of its being saved from destructive inflammation, though fragments of iron and steel are sometimes removed by means of a strong electromagnet, with a successful result. In these and all other *penetrating wounds*—i.e. those where the cornea or sclerotic is broken through, the possibility of subsequent sympathetic ophthalmia in the other eye must be borne in mind. When only partially sunk into the cornea, as is often the case with sparks of cinder or iron, &c., or 'fires,' as they are called, the rubbing of the projecting part on the eyelid causes great pain, and the surgeon has not much difficulty in removing them. Most commonly these, or other 'foreign bodies,' as particles of dust, sand, seeds, flies, &c., when not speedily washed away by the tears, merely get into the space between the eyeball and the lids, almost always concealed under the upper, as it is the larger, and sweeps the eye. They cause great pain, from the sensitiveness of the papillary surface of the lid, and of the cornea over which they are rubbed by its movements, soon excite inflammation, and their presence, as the cause, is apt to be overlooked. The lid must be turned round to find them. To do this, pull the front or edge of the lid forward by the eyelashes, held with the finger and thumb, and at the same time press down the back part of the lid with a small pencil or key, directing the patient to look downwards. The lid will readily turn round, when the body may be seen about its middle, and may be removed with the corner of a handkerchief. Another plan, which the person himself may try, is to pull forward the upper lid by the eyelashes, and push the lashes of the lower lid up behind it, when the foreign body may be brushed out. After the bodies are removed, a feeling as if they were still there may remain for some time. See BLIND, COLOUR-BLINDNESS.

ARTIFICIAL EYES are worn for the sake of appearance in cases where, as the result of disease or injury, an eye has either been totally lost, or rendered unsightly. They are, moreover, distinctly advantageous in cases where a gaping socket is liable to irritation by dust, cold winds, &c. They cannot be used unless the size and prominence of the eyeball is at least somewhat diminished. Few surgeons in Britain recommend them to be worn unless the eyeball is either entirely removed (enucleation), or has the front part removed

(abscission), or all the contents extracted (evisceration); for the artificial eye is apt to cause irritation of the sensitive anterior portion of the globe, and may lead to the development of sympathetic ophthalmia (see above). Enucleation is the most certain means of preventing this; but the other operations named above allow of better movement, and give a more natural appearance to the eye.

An artificial eye consists of a thin shell, usually of enamelled glass, coloured to present as nearly as possible the same appearance as the visible part of the normal eye. Celluloid (q.v.) has been used instead of glass, and is said to last better, as its surface is not affected by the secretions; while it has the advantage that it is not brittle, and can easily be pared to fit the socket accurately. Rubber eyes, enamelled in front, were introduced in 1916. To obtain a satisfactory result, it is necessary either to have an artificial eye specially made, or to be able to select from a very large stock; as colour of iris, size of pupil, tinge of sclerotic, as well as curvature of surface and form of margin, must be adapted to the particular case. They are therefore to be got to most advantage in large cities, such as London or Paris.

The eye must not be worn continuously, but removed each night and replaced in the morning. It is slipped in under the lids, which hold it in position. Even when the globe has been entirely removed, the muscles, by their attachment to the tissues remaining in the orbit, usually effect movements in the same direction, though not of the same extent, as those of the normal eye; and it is often difficult for any but a practised observer to detect to what the difference between the two is due. A single glass eye can rarely be worn more than a year without being polished, for the surface becomes roughened by the action of the tears, &c., and irritates the lids as they rub over it.

Common Eyebright
(*Euphrasia officinalis*).

Eyebright (*Euphrasia*), a genus of Scrophulariaceæ. The British species (*E. officinalis*), a plant of extraordinary variability, is a root-parasite common in pastures and grassy uplands, which at the end of summer are gemmed abundantly with its bright little flowers. From this general aspect and spotted corolla the popular name is derived; hence, too, the doctrine of signatures ascribed it an efficacy in the treatment of eye-diseases, which a mild astringency long aided it to maintain. It is the *Euphrasy* of Milton.

Eylau, a town of 3500 inhabitants, in East Prussia, 23 miles S. of Königsberg by rail. Here Napoleon encountered the allies—Russians and Prussians—under Bennigsen, 8th February 1807. Darkness came on while the contest was still undecided; but as Napoleon had a considerable force of fresh troops close at hand, the allies retired during the night upon Königsberg. Their loss is estimated at about 20,000; that of the French is set down at 10,000, but must have been considerably greater. The place is called Preussisch-Eylau, to distinguish it from Deutsch-Eylau (Polish, *Ilawa*), also in East Prussia, a town of 10,000 inhabitants, 75 miles ENE. of Bromberg.

Eyot, or AIT (O.E. *iggath*), a little island in a river, especially one overgrown with willows, as in the Thames.

Eyre, EDWARD JOHN, an Australian explorer and colonial governor, the son of a Yorkshire clergyman, was born in August 1815. Emigrating to Australia at the age of seventeen, he prospered as a squatter on the Lower Murray, and was appointed a resident magistrate and protector of the aborigines. In 1840 he failed in an attempt to reach the centre of the continent; he discovered and passed Lake Torrens, but was blocked by the great salt swamp afterwards called Lake Eyre (q.v.). On his way back he made for the coast at Port Lincoln, and followed it westwards, in spite of enormous difficulties, to Albany in Western Australia (*Discoveries in Central Australia*, 1845). In 1847–53 he was lieutenant-governor of New Zealand, and in 1854–60 of St Vincent in the West Indies. In 1862 he was appointed governor of Jamaica, where in 1865 negro disturbances broke out. The outbreak was suppressed with sharp, stern severity, martial law being proclaimed in the disaffected district; a wealthy mulatto named Gordon, a Baptist and member of the Jamaica House of Assembly, who had taken a leading part in instigating the rising, was hurriedly tried by court-martial, and hanged two days after, the sentence having been confirmed by Eyre. A commission sent to inquire into this case found that Gordon had been condemned on insufficient evidence, and Eyre was recalled. On his return he was prosecuted by a committee of whom John Stuart Mill was the most prominent; Thomas Carlyle, Charles Kingsley, and Sir R. Murchison promoted the Eyre defence fund. The prosecutions could not be sustained; and eventually in 1872 the government refunded to Eyre the costs of his defence. After 1874 he lived in retirement, and he died 30th November 1901.

Eyre, LAKE, a salt lake of South Australia, lying due N. of Spencer Gulf, at an altitude of 79 feet. Except in the season of rains, this lake is generally a mere salt marsh. It was discovered in 1840 by Eyre, who thought it part of Lake Torrens.

Eyre, JUSTICES IN. See ASSIZE.

Eyria Peninsula, on the south coast of South Australia, is triangular in shape, its base being formed by the Gawler Range, whilst its sides are washed on the SE. by Spencer Gulf, and on the SW. by the Great Australian Bight. It constitutes a rich pastoral country.

Ezekiel, one of the most important of the Hebrew prophets. Our knowledge of his career is scanty, and is derived entirely from his own statements in his prophecies. He was the son of Buzi, and together with Jehoiachin, king of Judah, was carried away captive by Nebuchadnezzar in 597 B.C. Little can be surmised about his earlier life, except that he must have been closely associated with Jeremiah: nor do we know his age at the time when the catastrophe befell him. In Babylonia he settled in a colony of exiles at Tel Abib on the banks of the river Chebar. His public ministry began in 592 B.C., and lasted for twenty-two years. He became the religious leader of the exiles, who formed an independent community and enjoyed the privilege of self-government. Ezekiel seems to have attained a commanding position, and his preaching became popular, though he failed to carry the people with him in his attempts to purify religion. The effect of his ministry is described in xxxiii. 30–33: 'Thou art unto them as a very lovely song of one that hath a pleasant voice and can play well on an instrument; for they hear thy words, but they do them not.' The Book of Ezekiel is comparatively free from any serious critical problems. The attempts of some scholars—e.g. Geiger,

Seinecke, and Zunz—to prove that it is the product of the Persian period, have entirely failed, and the book is now, by the general consent of modern scholars, regarded as authentic. The only point in dispute is as to whether the prophecies were collected together in their present form by Ezekiel himself or by a later editor. The book falls into four divisions: (1) The first part consists of chapters i.-xxiv., and contains the prophecies which were delivered before the final fall of Jerusalem in 586 B.C. In this section Ezekiel announces the complete overthrow of Judah, on account of its increasing unfaithfulness to God and its perjury in forming an alliance with Egypt when it had accepted the suzerainty of Babylon. (2) The second part (chaps. xxv.-xxxii.) contains a series of prophecies against the surrounding nations, Ammon, Moab, Edom, the Philistines, Tyre, and Egypt, and announces the final doom of Tyre and Egypt. (3) The third part (chaps. xxxiii.-xxxix.) contains the prophecy of the restoration of Israel. The revival of the people is depicted under the figure of the resurrection of an army of dry bones, and the promise is held out of the advent of an ideal shepherd who is to spring from the house of David. (4) The fourth part (chaps. xl.-xlviii.) gives us an ideal picture of the restored Israel and the reformed temple-worship. These chapters form a connecting link between Deuteronomy and the 'Priestly Code,' and pave the way for the introduction of the ritual of the Levitical system. As Dr Bennett says, 'Ezekiel represents a transition and a compromise: the transition from the ancient Israel of the monarchy to Judaism, and the compromise between the ethical teaching of the prophets and the popular need for ritual. He also marks the transition from the prophet to the scribe or theologian.' Among the other characteristics of Ezekiel we may note (1) the use of magnificent but artificial symbolism, which justifies Jerome's description of the book as a 'labyrinth of the mysteries of God.' (2) The stress laid throughout the book on the transcendence of God; (3) the constant emphasis on individual responsibility; (4) the introduction of apocalyptic elements into prophecy.

The most useful books are Skinner (*Expositor's Library*), Davidson (*Cambridge Bible*), Lofthouse (*Century Bible*). Among the more elaborate commentaries are those of Cornill, Bertholet, Smend, Keil.

Ezra, the leader of Israel's return from the captivity in Babylon. Our knowledge of his career is derived from Ezra, vii.-x.; Nehemiah, viii.-x.; and the apocryphal 1 Esdras. He is described as a 'priest' and 'a scribe,' and, according to the narrative, obtained great favour at the court of Artaxerxes Longimanus (464-425 B.C.). The *firman* in which Artaxerxes proclaimed the liberty of the Jews to return to Palestine (Ezra, vii, 11-26) is so favourable that considerable suspicion attaches to its genuineness. It seems hardly likely that Artaxerxes would have sent presents of gold and sacred vessels for Ezra to offer to God in the temple of Jerusalem. In 458 B.C. Ezra led a company of some 1500 men (the exact number differs in different

documents) out of Babylonia, and after a journey of four months reached the holy city. Soon after his arrival Ezra applied himself to the task of reform. The most serious problem that confronted him was the question of intermarriage. The Jews who had remained in Palestine had, in defiance of the law of God, intermarried with foreigners. In order to grapple with the situation Ezra summoned an assembly of the people and urged upon them the necessity of repentance, and besought them to annul these unlawful marriages. The proposal was not received with enthusiasm, and the meeting was broken up by a great storm of wind and rain. A commission, however, was appointed to remedy the evil. Ezra soon realised the impossibility of bringing the people as a whole up to his own standard of religion, and so he formed a society of men like-minded with himself, who pledged themselves to live according to the law of God. In 444 B.C. Ezra issued a new law to the people. There can be little doubt that this new law is represented by 'the Priestly Code,' which is now embodied in the Pentateuch (see BIBLICAL CRITICISM). The establishment of this code marked an epoch in the history of Israel, since it initiated the era of legalism.

The Book of Ezra is intimately connected with the Book of Nehemiah. Originally they were one document and formed a continuation of the Book of Chronicles. In their present shape they can scarcely have come into existence before the period 300-250 B.C. The author's name is unknown, but the interest which he displays in the Levites and the temple music suggests that he belonged to one of the Levitical choirs. The writer, however, embodied in these books earlier documents of varying value. There is a whole section of Ezra (vii. 27-ix.) which is written in the first person, and which is probably, therefore, derived from memoirs composed by Ezra himself. Another section of the book (Ezra, iv. 8-vi. 18; vii. 12-26) is written in Aramaic, and is clearly taken from an earlier source which is usually dated about 450 B.C. These two sections constitute the most valuable part of the book from a historical point of view. The first three chapters of the book are the work of the compiler himself; some of the statements found in them have been challenged by modern criticism, notably the account of the return of the exiles in the reign of Cyrus (537 B.C.).

See commentaries by Ryle (*Cambridge Bible*), T. Wilton Davies (*Century Bible*), Bertheau-Ryssell, Keil, Schultz; Sayce, *Introduction to Ezra, Nehemiah, and Esther*; Hunter, *After the Exile*; Torrey, *The Composition and Historical Value of Ezra-Nehemiah*; Cheyne, *Jewish Religious Life after the Exile*.

Ezzelino da Romano, an Italian Ghibelline family, whose most famous and warlike representative, Ezzelino or Ecelino IV. (1194-1259), *podestà* of Vicenza, is known from Dante as notorious for cruelty. He won many victories for Frederick II., but was ultimately wounded in battle, defeated, and captured; he died in prison, and all his family were put to death.

F

the sixth letter of our alphabet, represents the sixth letter, *wāw*, of the ancient Semitic alphabet, which denoted primarily the consonant *w*, and secondarily the cognate vowel *ū*. The word *wāw* in Hebrew means a curtain-pin, but it has no affinities in Semitic, and probably the curtain-pin was so called because its shape resembled that of the letter, which in early inscriptions appears as I. The name *wāw* was, on this view, an arbitrary invention intended to express the sound which it contains twice over; in Hebrew and Aramaic initial *w* is so rare that it was impossible to provide the letter with a name signifying a visible object. The shape of the letter underwent various modifications in the later Semitic scripts, becoming in Hebrew ו, in Syriac ܘ, ܥ, and in Arabic و.

In early Greek use the letter assumed two forms, Y, which is very close to the original type, and F, which is a modification probably due to assimilation to the preceding letter E. In the oldest inscriptions these two forms are already differentiated in function, F being used for *w*, and Y for *u*. The consonant-sign F retained the sixth place in the alphabet, while T (the ancestor of our U, V, W, and Y) was placed after T, the last of the original 22 letters.

The sound *w* and its symbol eventually disappeared from the Greek language (see DIGAMMA), but were still in use when the alphabet was adopted by the Romans. The sixth letter in its original function was found by the Romans unnecessary, as their *w*-sound was merely a devocalisation of *u*, and could be represented by the same symbol as the vowel, namely V. Latin, however, had one consonant-sound (nearly or exactly that of our *f*) unknown to the Greek language, and it was necessary to provide a sign for this. The nearest Greek sound was *wh*, which was written FH. Hence in early Latin inscriptions the sound *f* was rendered by FH; but it was soon perceived that the H could be dispensed with. The modern forms of the letter are obviously derived from the Roman F; our script *f* has lost all resemblance to the original, but it is easily seen to result from the attempt to join *f* to the preceding and following letter without taking off the pen. In mediæval MS. the minuscule *f* was often doubled to serve as a capital; a survival of this practice is seen in the spelling of certain surnames, as ffoulkes, ffarington.

In nearly all languages written in the Roman alphabet, F retains its Latin sound—the voiceless labial spirant. In early Latin it was perhaps bilabial, but afterwards became dentilabial (formed between the upper lip and lower teeth) like the *f* of most modern languages. In Old English *f* was in the middle of words pronounced like our *v*; in Welsh a single *f* has always this value, the sound of our *f* being expressed by *ff*.

In Irish written in the native character, an etymological *f* which has become silent is written *f̊*; in transliterated Irish and in Scottish Gaelic *f̊* is substituted for this. In modern English the only exception to the normal pronunciation of the letter

is the word *of*, where the *f* has been pronounced as *v* from Old English times.

The Latin name of the letter, *ef*, is, like those of L, M, N, R, S, formed differently from those of the stopped consonants, *be*, *ce*, *de*, &c. The reason probably is that as the spirants, liquids, and nasals are capable of prolongation at the end of a syllable, their sound was more distinct in a final than in an initial position. The name is preserved in the modern European languages, but has become dissyllabic in Italian (*effe*) and Spanish (*efe*).

F, in Music, is the fourth note of the natural diatonic scale of C. See MUSIC, SCALE, KEY.

Faam, or **FAHAM** (*Angræcum fragrans*), an orchid, native of Madagascar, &c., prized for the fragrance of its leaves, which is owing to the presence of *Coumarin* (q.v.), and resembles that of the Tonka Bean and of Vernal Grass. In Mauritius an infusion of faam leaves is in great repute as a cure for pulmonary consumption and as a stomachic. It has also been imported into France as Isle of Bourbon Tea (*folio faham*), and used in infusion and as a source of perfume.

Fabaceæ. See LEGUMINOSÆ.

Faber, CECILIA. See CABALLERO, FERNÁN.

Faber, FREDERICK WILLIAM, hymn-writer, was born at the Yorkshire vicarage of Calveley, 20th June 1814, passed from Shrewsbury School to Harrow, and thence to Balliol College, Oxford, and in 1834 was elected a scholar of University College, in 1837 a fellow. Already he had come under the spell of Newman, and in 1845, after three years' tenure of the rectory of Elton, in Hunts, he followed him into the fold of Rome. He founded a community of converts at Birmingham—then Wilfridians, he himself being Brother Wilfrid, from his *Life of St Wilfrid*, published in 1844. With his companions he joined in 1848 the Oratory of St Philip Neri; next year a branch under his care was established in London, finally located in 1854 at Brompton, where he died 26th September 1863. Faber wrote many theological works; but his fame will rest upon his hymns—'The Pilgrims of the Night,' 'The Land beyond the Sea,' &c. A collection of 150 hymns was published in 1862. See the *Lives* by J. E. Bowden (1869; new ed. 1892) and his brother, F. A. Faber (1869).

Faber, GEORGE STANLEY, Anglican divine, was the eldest son of the Rev. Thomas Faber, and was born at Calverley vicarage, near Bradford, 25th October 1773. He entered University College, Oxford, in 1789, and four years later was elected Fellow and Tutor of Lincoln College. As Bampton Lecturer for 1801, he delivered the lectures subsequently published under the title of *Horæ Mosaicæ* (1801). In 1805 he became vicar of Stockton-on-Tees, and, after several changes, received in 1832 the mastership of Sherburn Hospital, near Durham. He died at Sherburn on 27th January 1854. Of Faber's numerous theological works, those on prophecy were most popular.

Faber, JOHN (1684-1756). See ENGRAVING.

Fabianism. The Fabian Society is the name chosen by a body of English Socialists who, in the year 1884, came together at a series of private

meetings in London for the discussion of social problems in general, and in particular of the views of a Scottish-American thinker, Thomas Davidson, who was then visiting England and endeavouring to rouse interest in the philosophy of Rosmini. The group formed around Davidson divided, after his return to America, into two sections, one of which survived for some years as the Fellowship of the New Life, and was lost sight of. The other, more matter-of-fact, militant, and political, established itself as the Fabian Society. All trace of Davidson's influence soon vanished; but the character of the Society was determined by its origin in a group of educated persons of the professional and higher official classes, including civil servants of the upper division, stockbrokers, journalists, and the propertied bourgeoisie generally, all under the age of thirty, with their careers still before them.

At that date Socialism, after a period of disrepute and almost of oblivion following the sanguinary suppression of the Paris Commune of 1871, had revived with extraordinary force and rapidity. The keenest of the converts to land nationalisation made in 1882 by the lecturing campaign of Henry George, and by his book *Progress and Poverty*, were carried on by the impetus of their conversion to the study of Karl Marx and Proudhon, and the formation of Societies of Land Nationalisers, Social-Democrats, and Anarchists, all aiming at the redemption of the wage workers from poverty, and looking to that class for their recruits, who were enlisted by public harangues at subscriptions of a penny a week, the program being to continue the process until an overwhelming majority of the workers had joined, when the Society would reconstruct European society on Georgist, Marxist, or Proudhonic lines.

Such Societies, hopeless and useless except for agitating and demonstrating against the unemployment and misery of the period of bad trade then prevailing, had no attraction for critical students of the great evangelists of the movement, especially for the politically experienced ones, much less for upper division civil servants with a practical knowledge of government and administration. The Fabian Society gave these students just what they wanted: a nucleus for a Society of their own class, and a name which proclaimed a literate atmosphere and a sane and patient temperament. Also, as the name suggested nothing else, the Society offered them an unformed constitution out of which they could make what they pleased. For several years the Society had less than forty members, who met in one another's drawing-rooms and administered an income from subscriptions of less than £40 a year. There was no fixed subscription: members gave what they could afford. There was no recruiting; and excitable or eccentric applicants for membership were discouraged and, if necessary, excluded. Members had to sign a declaration that they were Socialists, and that they accepted the Basis, a document stating the aim of the Society as 'the re-organisation of society by the emancipation of land and industrial capital from individual ownership, and the vesting of them in the community for the general benefit.' To this was added 'the transfer to the community, by constitutional methods, of all such industries as can be conducted socially,' and 'the establishment, as the governing consideration in the regulation of production, distribution, and service, of the common good instead of private profit.'

The Society soon asserted its critical independence of Socialist dogma, and affirmed its constitutional and practical character. A nominally

separate body, called the Hampstead Historic Society from its place of meeting, but really a committee of the leaders of the Fabian Society, conducted a critical examination of Marx, and rejected his theory of value. This was followed by a less thorough examination of Proudhon's famous thesis that property is theft, mainly because this work had been for some reason adopted as a sort of gospel of Anarchism in opposition to Marx's *Das Kapital*, 'the Bible of German Social-Democracy.' These critical exercises were then discarded; and a course of original and independent study entered upon, with the result that in 1889 the Society published *Fabian Essays*, which, first issued as a six shilling volume, was so successful that a cheaper edition was hastily prepared, and gained a large circulation which has continued steadily up to the present moment. In these distinctively English essays there is no trace of Marx or Proudhon or the earlier revolutionary veterans of 1848. The economics, consisting of Ricardo's law of rent, and Jevons's law of value, are quite orthodox. It is shown that the entry of the State into productive industry, far from being an untried, dangerous, and economically unsound innovation, is a fact already accomplished and in successful operation to an extent hitherto unnoticed. The notion of a sudden change from Capitalism to Socialism by the physical force of an insurrection is ridiculed and dismissed as 'catastrophic Socialism'; and the transition from Capitalism to Socialism is dealt with as part of the course of ordinary constitutional evolution. Heterodoxy in religion is omitted as entirely irrelevant. Socialism, in short, is presented as the creed of a constitutional political party pursuing its aims precisely as any other constitutional political party does, and involving no sacrifice whatever of current respectability and morality on the part of its adherents. This, at a time when Socialists were still very generally regarded as outlaws, and when the majority of avowed Socialists were themselves so saturated with revolutionary romance that they protested vehemently against every attempt to open their ranks to the conventionally behaved bourgeoisie and the clergy, was a step in advance which soon became imperceptible through its general acceptance.

In the meantime the Fabians had been the first to grasp the opportunity offered to practical Socialism by the possibilities of municipal enterprise; and when the Local Government Act of 1888 was passed, and the London County Council established, they circulated leaflets suggesting questions to county councillors in which, without any mention of Socialism, candidates were invited to pledge themselves to reforms involving various forms of direct municipal enterprise without the intervention of private commercial contractors, and to clear themselves of all suspicion of being opposed to 'moral minimum' wages or the abolition of sweating. The candidates for the new bodies, having no platform and no traditional policy to fall back on, snatched at the program thus adroitly suggested; and the policy of the supply of public needs by municipal trading, and the safeguarding of the interests of the 'workman by fair wages clauses, suddenly took shape in London as Progressivism. It was vigorously denounced and ridiculed as 'gas and water Socialism' by the other Socialist bodies; but it was extraordinarily successful at the polls, and retained its hold on London until the turn of the century, when the reaction towards official Liberalism which followed the South African war, and the rally of the Free Churches against the subsidisation of the Church of England

elementary schools by the Education Act of 1902, enabled the old parliamentary Liberals to oust the Fabian Progressives and replace them by Liberal partisans, with the unexpected result that the Progressive party in the Council, in ceasing to be Fabian, also ceased to be popular.

The success with which the Fabians imposed a program on the London County Council encouraged them to try their hands on the House of Commons. The method they adopted was that of Permeation, a word which they made current in Socialist and Labour politics as indicating Fabian tactics. Unlike the older societies, which held aloof from and excluded from their ranks members of all ordinary political bodies, the Fabians not only placed no restriction on their members as to their activity in other quarters, but actually urged them to join every other body to which they could obtain admission, in order to permeate these bodies with Socialist ideas, and persuade them to advocate Socialist measures. They had observed that, no matter which political party was in power at the moment, the Opposition was sure to be critical, impatient, and clamorous for reform. On this ground the Liberals, then in opposition, were first selected for permeation. Their local associations suddenly received several active and intelligent recruits; and the National Liberal Federation presently found itself committed to a series of resolutions of an unprecedented character, which were adopted at the annual conference of that body at Newcastle in 1891, and were thenceforth known as the Newcastle Program.

The general election of 1892, which the Liberal leaders wished to fight on the issue of Home Rule for Ireland, justified the bold assertion of the Fabians that the English working-class, worse off in many respects than the Irish, 'did not care a cump' for Home Rule, and that the election must be fought on social reform. The Liberal candidates, after their first taste of the temper of the electorate, hastily distributed Fabian pamphlets, made Fabian speeches, and won by a hair's-breadth. But their leaders, to whom the Fabian Society was hardly known, and the new departure repugnant and indeed unintelligible, dropped the Newcastle Program when they took office. The result was that two years later the Fabian Society, in a manifesto entitled 'To your Tents, O Israel,' which appeared in the *Fortnightly Review*, delivered a slashing attack on the Liberal government, making effective use of its technical political knowledge to discount the Government's plea that the slaughtering of its measures by the House of Lords and the slenderness of its majority in the House of Commons made any progressive legislation impossible. The Fabians produced a long list of administrative reforms promised in the Newcastle Program, which needed only the stroke of a minister's pen. No effective reply was forthcoming. The Liberal leaders sulked disdainfully; and Lord Rosebery only remarked that he had said all along that the Newcastle Program was a mistake, like all programs. The Government quite underestimated the force of the blow, and in 1895 went into opposition for eleven years.

This stroke made an end of the direct political influence of the Fabians. Thenceforth they were intensely disliked and distrusted by the official section of the Liberal party, all the more as the Fabians made no secret of the fact that they had foreseen what would happen, and that the attack on the Liberal party was part of their original plan, which was now developed by the republication of the manifesto by way of preamble to a pamphlet entitled *A Plan of Campaign for Labour*, which laid down the lines for the formation of an independent Labour party in parliament.

But the long habit of regarding the Liberal party as the party of progress and the necessary instrument of every political advance made the Fabian attack on it almost as bewildering and scandalous to the working-classes as to the official Liberals. The older Socialist Societies, still unreconciled to the new Fabian tactics, encouraged the inference that those who attacked the Liberals, except from the extreme revolutionary point of view, must do so in the interests of the Tories, probably under the influence of bribes. The plan of campaign for Labour was not taken up; and the Fabian Society could only mark time until their temporary disrepute was aggravated by the outbreak of the war in South Africa. It was assumed on all hands that the Liberal Opposition, the working-classes, and the Socialists must oppose the war as a war of Capitalism, and support the Boers as its victims. The Fabian Society, in a pamphlet entitled *Fabianism and the Empire*, unexpectedly took the opposite view, and, for reasons that were as little to the taste of the Government as of the 'pro Boers,' gave up the theocracy of President Kruger as obsolete and impossible, and declared for a consolidated British South Africa on the lines on which the final settlement was actually achieved. The Society, already suspected of Toryism, now stood convicted of Jingoism; and the limit of suspicion and discredit with the Liberal-Labour section was reached when the war was followed by a Conservative Education Bill, which threw the support of the Church schools on the rates. This roused all the old Nonconformist hatred of the Church which had been sown by the intolerance and class bias of generations of country parsons and squires, and which found expression in the Passive Resistance movement. But the Fabians again took the unexpected line of demanding public money for the Church schools on the ground that half the children in the country had no other schools to go to, and that only by financing the schools could the State impose on them the inspection and regulation needed to put an end to their abuses.

The breach of the assumed but wholly imaginary alliance between Liberalism and Fabianism was now apparent to all parties; but in the meantime the proposal for an independent Labour party in parliament had been vigorously pushed by a new body, the Independent Labour party, led by Keir Hardie and Mr Ramsay MacDonald. As its propaganda spread, detachment from the Liberal party became a qualification for the confidence of the workers instead of a bar to it; and the co-operation of the Fabians was welcomed when the Labour Representation Committee was founded in 1900. The Fabian Society was granted representation on the committee; and when, after the sensational Liberal and Labour victory at the general election of 1906, the Labour party became an accomplished parliamentary fact, the Fabian Society was affiliated to it, and allowed to retain its representation on the committee.

By that time the relative situation of the Society had altered considerably. During the twenty-two years of its existence Socialism had become Fabianised throughout Europe. Edward Bernstein, exiled by Bismarck in the 'eighties for his Socialism, had taken refuge in London; and, at the strenuous early debates of the Fabians, had heard the old doctrinaire Marxism torn to pieces, and a constitutional parliamentary and municipal Socialist program elaborated. Returning to Germany, he had divided the Social-Democratic party by heading a Fabian revolt against the old leaders, which became known as Revisionism. Vandervelde in Belgium, Jaures in France, and Turati in Italy had become leaders of parliamentary Socialist

parties which had everything in common with the once distinctive features of Fabianism, and nothing in common with the veterans of 1848-71 whom the Fabians had superseded. In Australasia Labour parties had actually achieved parliamentary majorities, forming governments, and carrying into law many projects suggested and inspired by Fabian Essays and the long series of Fabian tracts which had supplemented them. Constitutionally, the Fabians were no longer pioneers: the ground they had broken was now occupied by the whole European centre of the Socialist movement.

Also, the Fabian leaders were no longer young men. Their personal ability had brought them work which inevitably competed heavily with the Society for their time and energy, and along with it a personal celebrity which made Permeation no longer possible for them as an unnoticed process. Sir Sydney Olivier [Lord Olivier], secretary to the Society for some years in its early days, distinguished himself in the colonial service; and finally, as Governor of Jamaica, could no longer take a direct personal part in the councils of the Society. Mr Bernard Shaw, achieving success as a playwright, first in America and Germany, and later on in England, substituted the theatre for the platform of the Fabian Society, and the prefaces to his published plays for Fabian pamphlets, as his chief means of propaganda. Mr Sidney Webb, on his marriage with Miss Beatrice Potter, whose genius for economic and industrial investigation had already declared itself, devoted himself to the monumental series of investigations into the history and structure of industrial democracy which are associated with his name and that of his wife, and to the foundation and development of the London School of Economics. Mrs Annie Besant, whose extraordinary gift of oratory for some years placed any public meeting in London at the mercy of the Fabian Society, passed through Socialism to Theosophy, and from London to India. Mr Graham Wallas, another of the Fabian essayists, became absorbed in the administration of public education, in professorial lecturing, and in sociological authorship. The late Hubert Bland found a new platform as a popular journalist. William Clarke, another very able essayist and journalist, died at a comparatively early age. The late Frank Podmore, whose studies of Owenite Socialism and its American derivatives are well known, was detached from the Society by his interest in psychical research. Mr Edward R. Pease, who was a stockbroker when the society was formed, became a working cabinetmaker for some years before rejoining the executive of the Society as its secretary, thereby acquiring direct personal experience of artisan life, an adventure parallel to that of Mrs Sidney Webb, who worked in disguise in the sweaters' dens of East London to investigate the conditions of the tailoring trade there. Mr Pease subsequently wrote a history of the Society.

The names of these makers of the Fabian Society are important, because their subsequent careers explain how it produced an effect on the Socialist movement, and on political thought generally, out of all proportion to its numbers and apparent resources. Largely by choosing its name happily, it attracted a handful of persons of more than average ability, with exceptional gifts of literary and oratorical expression. This concentration of talent was effected at a time when its possessors, being young and unknown, could enter unnoticed into the bodies in which they carried on their missionary work, and send their communications to the press in the disguise of ordinary professional journalists. The work done by them during the first ten years of the Fabian Society's existence was prodigious in quantity, and has been far-reaching in its effect;

but the Press of that period, preoccupied with the Home Rule controversy and the party routine of the House of Commons, contains no record of it. One of their number has said: 'In the strength of my youth I delivered harangues, lasting from an hour to four hours, with long discussions afterwards, during a period of twelve years, at the average rate of three every fortnight, to large audiences; and nobody took the smallest notice of them. Now I cannot make the most trivial remark without finding it misquoted in half-a-dozen papers.'

In 1903 the Society made a brilliant recruit in Mr H. G. Wells, who called attention to the impossibility of developing Municipal Socialism within the limits imposed by our obsolete municipal boundaries. Later on Mr Wells tried to use the Fabian Society as an instrument for the social reconstruction he had sketched in his *Anticipations*. His project was received with enthusiasm by the whole Society; but the internal reforms he proposed included the superannuation of the older leaders, whose practice in debate, and dexterity in the handling of meetings and committees, made the task of adapting his proposals to their practical criticisms too tedious and irksome for his patience. The members recoiled from so violent a break with the traditions of the Society; and Mr Wells withdrew quietly after their refusal.

In 1907 'the equal citizenship of men and women,' always advocated by the Society, was added explicitly to its written Basis.

In 1909 the effective permeation of the Royal Commission on the Poor Law by Mrs Sidney Webb resulted in the issue by that body of a notable Minority Report, which gained so much support outside the ranks of professed Socialists that Mrs Webb was obliged to form a nominally new Society to push its proposals. It contains the Fabian solution of the unemployed question, and the Fabian proposals for the abolition of the poor law, and the redistribution and reorganisation of its functions.

By this time parliament was attempting to solve in its own way the social problems which the earlier Fabian propaganda had forced into English public consciousness and into colonial legislation. The Society consequently found itself occupied in severe criticism of the Government's methods, notably in the case of the Insurance Act of 1912, in framing which the Chancellor of the Exchequer ignored the investigations and proposals of the Fabians and their school, and went to Germany for his model, reproducing all the inconveniences and mistakes of the German experiment, and provoking a vehement agitation which threatened to wreck his party at the next general election. The old Fabian plan of prompting the politicians was useless now that Ministers were taking up Socialism in a crude form, and going to work upon it with a determination to owe nothing to the Fabians, who had become impatient of the want of skill and knowledge shown by the party politicians, and somewhat dictatorial in their solutions of the problems affecting the standard of life of the working-classes. The old wire-pulling had therefore to be dropped and replaced by public prompting; and this involved control of a weekly review of high political and literary quality, capable of doing for Collectivism what *The Spectator* and *The Nation* were doing for Unionism and the higher Liberalism. The Fabian leaders accordingly founded *The New Statesman* in 1913. The supplements on social questions, which were the distinctive feature of this weekly review, were really a development of the Fabian tracts. There was no formal official connection between *The New Statesman* and the Fabian Society; but as the staff and directorate were predominantly Fabian, *The New Statesman* was really a creation of the Society, and

was its public mouthpiece until, in the course of time, it inevitably developed a journalistic individuality of its own. The Society's official organ, *Fabian News*, is a monthly sheet which has existed since 1891, and has no circulation outside the Society.

The war of 1914-18 affected the Society favourably by compelling the Government to supersede private commercial enterprise in several directions by direct State control, and to save the banks by guaranteeing the foreign exchanges: steps which could not have been proposed and accepted, virtually without protest, but for the extent to which the Fabian Society had educated the public and the official classes to resort confidently to State action in spite of the traditions of the Manchester school. The unprecedented taxation and super-taxation of property for the support of the war was also in line with the Society's propaganda. The war, however, revealed the political futility of international Socialism, and the helpless nullity and ignorance of British Socialism and Labour in the sphere of foreign policy. The Fabian Society, therefore, turned its attention for the first time to the subject of what it called supernational law and political organisation, and produced, through the International Agreements Committee of its Research Department, plans for a supernational legislature and tribunal which were published as supplements to *The New Statesman*. In the meantime it identified itself, by a series of six public meetings held in London, Mr Bernard Shaw being spokesman, with his propaganda of equality of income as the economic goal of Socialism, but without committing itself to this article of faith.

A general survey of the Society's activities after the detachment of Labour from capitalist Liberalism in parliament, and its establishment there as an independent party, with an independent national political organisation, shows the Fabians as gradually disentangling themselves from the wire-pulling and tactical intrigue forced upon them in the last decade of the 19th century by the necessity of working through hostile parties in parliament, and outwitting them, and by the fact that at that time they alone, among the organised Socialists, knew enough of the arts of government under our system to be qualified for the work. This disentanglement was motivated by the desire to get back to the true function of the Society in the investigation of social conditions, and the study and practical solution of the problems raised by them. The Society's centre of gravity became its Research Department, in which some of the older leaders, who had withdrawn more or less from the general management of the Society, for a moment resumed their activity side by side with the younger generation. For a few years this body worked with feverish energy as the intelligence department of the Labour Party during the great railway and coal-mining strikes which followed the war; but the sympathy of some of its most energetic young members with the Russian Bolsheviks produced a split which ended in their defection, and in the formation of a new Research Department by the Labour Party, which virtually absorbed and superseded the Fabian Department. The general election of 1922, at which Mr Sidney Webb entered parliament as a member of a greatly reinforced Labour Opposition, marked the final transfer of the political activities of the Fabian Society to the front benches of Labour in parliament.

The Society, nevertheless, maintains its existence as a relatively small and select body of constitutional Socialists, informing and prompting other bodies and public opinion, and acting through them whenever possible. Many of its numerous tracts have become obsolete through

the passing of their proposals into law; but some of the earliest are still in active circulation. Local Fabian societies have been formed in the provinces. Of these the oldest and most important is the Liverpool Fabian Society. Fabian Societies, with a continually changing membership, existed for many years at the universities; but most of these became University Labour Clubs after the war. The number of persons distinguished in the literary and political world who have at one time or another been members of the Fabian Society is considerable; and though some of them may now regard the experience as a sowing of their political wild oats, the share taken by the Fabians in the education of the generation which followed that to which their leaders belonged has left its mark on political history, and will probably continue to influence it more or less until the Collectivist reaction against the Manchester School is consummated or exhausted.

Fabius, the name of one of the most illustrious patrician families of Rome.—**QUINTUS FABIVS RULLIANUS**, a general in the second Samnite war, was dictator (315), censor (304), and six times consul.—**QUINTUS FABIVS MAXIMUS VERRUCOSUS**, five times consul and twice censor, was elected dictator (221) immediately after the defeat of the Romans at Trasimenus. The peculiar line of tactics which he observed in the second Punic war obtained for him the surname of Cunctator ('Delayer'). Hanging on the heights like a thundercloud, to which Hannibal himself compared him, and avoiding a direct engagement, he tantalised the enemy by the favourite devices of guerilla warfare; he harassed them by marches and counter-marches, and cut off their stragglers and foragers; and at the same time his delay allowed Rome to assemble her forces in greater strength. But this 'Fabian policy' was neither appreciated in the camp nor at home; and shortly afterwards, Marcus Minucius Rufus, Master of the Horse, was raised to an equal share in the dictatorship. During his fifth consulship Fabius recovered Tarentum (209 B.C.), which had long been one of Hannibal's important strongholds. He died in 203 B.C.—**CUNCTATOR FABIVS**, surnamed Pictor, executed in 302 upon the walls of the temple of Salus the earliest Roman painting of which we have any record. His grandson, **QUINTUS FABIVS PICTOR**, was the first writer of a Roman history in prose.

Fable, as defined by Dr Johnson in his *Life of Gay*, is, 'in its genuine state, a narrative in which beings irrational, and sometimes inanimate—*arbores loquuntur, non tantum feræ*—are, for the purpose of moral instruction, feigned to act and speak with human interests and passions.' It is thus almost synonymous with the apologue, and closely allied to the allegory and the parable, but it need not be at all probable in its incidents, its essential motive being merely a moral or didactic end effected by any means, while its composition is due to mere or less conscious literary art. In earlier times the name was frequently used as synonymous with myth, but this sense was dropped when a deeper insight into the mental condition of primitive man had revealed how small a factor conscious fiction was in the making of so composite a product as the mythology of a people. It is usual again to differentiate the parable from the fable as especially conveying spiritual truths, and not transgressing possibility and the actual order of nature; but, leaving out of sight the special examples in the New Testament, it is impossible to make so sharp a distinction between moral and religious truths. In the earlier stages of the history of every people the human intellect has employed itself in rudimentary meta-

physical speculations, and hence a host of myths have arisen everywhere of themselves to account for natural phenomena, the origin of man, and the like, which in many cases have been preserved. These myths are of course quite innocent of moral, and, indeed, in the hopeless confusion of a composite mythology, are usually strangely inconsistent with considerations of morality, being survivals of an irrational state of mind to which they seemed natural enough. Side by side with this process in the mind of many peoples, a rudimentary literary faculty early began to exercise itself, giving rise to real fables. One large class, indeed the most important, whether from the point of view of quality or of quantity, takes the form of fables about beasts, with whom primitive man has no difficulty in feeling a sense of affinity. These again develop with progressive culture and a growing moral sense into the didactic apologue, and thus reach the class of fables proper, as being essentially due to conscious literary art. These, unlike the myths that have grown spontaneously as an attempt to find concrete expression for those ideas and impressions about the relations between man and the physical world that lie at the basis of religion, lend themselves early to transmission, and have actually, as we shall see, travelled round the world. The folklore of even the rudest people contains many complex elements, but it is only as culture begins to advance that we find the beginning of the literary fable proper, although it remains true that a large number of the folk-tales are more or less perfect fables. While this is true, it is no less so that it is merely in half-civilised communities that the fable attains its greatest perfection. We find the moral apologues so dear to the oriental mind ranging in a thousand forms, from the scriptural example of Jotham to the elaborate and involved examples in the *Arabian Nights*.

The old French *Fabliaux* have little in common with fables beyond a name of similar origin, being short tales in verse, essentially satirical, or rather representing human things under the light of a ludicrous or only half-serious mockery. Of the genuine fables of medieval times the greater number were associated with the name of *Æsop*, whom it is usual for classical scholars to place in the 6th century B.C. Certainly his name occurs frequently in classical literature as that of a fabulist, but the so-called *Æsopic* fables that have come down to us are far from being Greek in character, to any great extent at least. The collection formed by Planudes of Constantinople in the first half of the 14th century has much in common with the metrical Greek fables of *Babrius*, who lived most likely in the 1st century B.C., and again with the Latin fables of *Phædrus*, a freedman of Augustus, because the ultimate source of many fables of these and other fabulists was the same—the Buddhist birth-stories and other Indian tales, which had long before been gradually finding their way westwards through Arab or still more obscure channels. Many of our Greek fables are substantially identical with the Buddhist *Jātakas*, and can be explained on no theory but that of simple transmission, often within even historical times. This much at least is certain, that a considerable part of the *Æsopic* fable reached the Greeks from the East, however obscure our knowledge of the methods of transmission may yet be. The medieval examples of the fable follow closely the two Latin versions (1) of *Avianus*, comprising fables in distichs, rendered at a later period into prose, and almost all borrowed from the immediate Greek originals bearing the name of *Æsop*; and (2) to a still greater extent a prose version of the fables of *Phædrus*, represented in the prologue as a translation into Latin of the Greek fables of *Æsop* by a certain Emperor

Romulus for his son *Tiberinus*. The Latin *Romulus* was enlarged about the 11th century by a number of fables of quite a different character, bearing in the highest degree the stamp of the middle ages, and often of Christianity (as in that of the wolf who learns to read), coming in great part from India, by way of Byzantium, most frequently badly told, usually very obscure, but often original, well invented, and of a very popular character, as in that of the cat that has put on a stole in order to baptise a rat which wishes to remain a Pagan. The collection as thus increased originated without doubt in England, and at an early date was rendered in English, and associated without reason with the name of Alfred. It was from this lost English version that it was translated, in the reign of Henry II., by Marie de France, into elegant but somewhat dry French verses. She gave her work the name of *Isopet*, the title of all medieval collections of fables, itself really a mere familiar diminutive of the name of *Æsop*, to whom all apologues were always attributed. About the same time Walter the Englishman, or Gualterus Anglicus (probably) rendered into Latin distichs the first three books of *Romulus*, comprising fifty-eight fables, to which he added two stories, one from an unknown source, the other borrowed from the *Disciplina Clericalis* of Petrus Alphonsus, a 12th-century converted Jew, whose work is a book of moral instruction, filled with stories of Arab (and ultimately Indian) origin. According to custom, Walter's collection of fables (Henryson's chief source) was connected with the name of *Æsop*; its pretentious style brought it great success, and we have extant two verse translations of the 13th and 14th centuries, the *Isopet de Lyons* and the *Isopet II. de Paris*—the last called also the *Isopet-Avionnet*, because the translation of *Æsop* therein follows that of *Avianus*. Another redaction, by Alexander Neckam (12th century), in Latin distichs, was twice translated into verse in the *Isopet de Chartres* and the *Isopet I. de Paris*. Of these translations the most interesting, because the freest, is the *Isopet de Lyons*; all alike abound in misconstructions, to which the obscure language of their models lent itself too easily, and from which the rhymers extricate themselves as best they can.

Besides these special collections of fables, the best and most original examples, whether in French or Latin, are often to be found in the works of the moralists, the preachers, and even the historians, as, for example, in the *Récits du Ménestrel de Reims* (1260), a collection of semi-popular and current hearsay traditions, having for its point of departure the first Crusade, and loosely connected with the Holy Land, France, England, and Flanders. From the 12th century there were often inserted in sermons *Exempla*, or short tales, sometimes edifying in themselves, sometimes having the character of parables or even merry stories, from which the preacher at the end extorted a moral. These were stories merely Christianised for the ends of edification, and were very frequently nothing more or less than time-honoured fables. The collection in French by the English Franciscan Nicole Bozon (13th century) is particularly rich in such fables told in a lively and popular manner. Side by side with these fables transmitted by the clergy there circulated among the people many beast-fables, which, like the primitive examples of African and other savage peoples, are destitute of any moral aim, but unlike these are due to conscious literary art in depending mainly upon a sympathetic and humorous observation of certain animals, whose adventures conform to their supposed character and their known habits. A great many of these stories have for their theme the struggles between the wolf, the stronger, and the fox, the more cunning, which ends always in the former being worsted. The great innovation

which developed out of these a kind of beast-epic was the individualising of the heroes and giving to them proper names; the figures with which we are concerned are no longer a wolf and a fox, but Isengrim and Raganhard, with their wives Richild and Hersind (later Isengrin, Renard, Richeut, Hersent). Around these principal personages the action centres, and beside them we find a crowd of secondary actors: Noble the lion, Grimbart the badger, Belin the ram, Chanteclair the cock, Couard the hare, Tibert the cat, and Bernard the ass, who throughout preserve their characters and play consistent parts. This ingenious and artistic transformation may have originated in the north of France about the 11th century, but quickly spread over western Europe in Latin, German, and Flemish versions, and, both from the intrinsic interest of the theme, and its adaptability to satirical purposes, as well as its admirable artistic treatment, exercised a powerful influence over the popular imagination from the dark ages to the age of Goethe.

The pure fable of medieval times followed closely its venerable originals, as we find them still in our *Panchatantra*, *Hutopadesa*, and *Kalilah wa Dimnah*; but our modern examples have little beyond what is external in common with these, for the fable has long ceased to be a natural form for literary expression in prose or verse. The fables of Pior, Moore, and Gay are lively and often graceful poems, but they have usurped a name to which they really possess no claim. Nor are Dryden's so-called *Fables* fables at all, however effective as poems they may be. Quite different is the case of the great master of fabulists, the inimitable La Fontaine, who possessed one merit rarer even than his exquisite blending of humour and pathos and his matchless perfection of form, in that 'infantine familiar clasp of things divine' in which lies hid the real essence of the fable. No successor has discovered the secret of that exquisite naïveté on which depends his charm, although the imitators of this new form in literature have been countless in number. Gellert's German fables (1746) were among the most popular of these, and first attracted the great Lessing into imitation. The latter published his famous *Fabeln* in 1759, together with a striking essay on the history and meaning of the fable in literature, the conclusions of which were mostly much more subtle than always sound. Of more recent fables the best are a few examples among the exquisite prose fairy-tales of Hans Christian Andersen and in the verse of Krilof: everywhere else the making of fables would appear to be an art that is lost without hope of recovery.

See the articles *ÆSOP*, *BEAST-FABLES*, *BIDPAI*, *FABLIAUX*, *FOLKLORE*, *MYTHOLOGY*, and *REYNARD*; also Max Müller's essay 'On the Migration of Fables,' in vol. iv. (1880) of *Chaps from a German Workshop*; W. G. Rutherford's dissertation on 'The History of Greek Fable,' in his edition of *Babrius* (1883), which is good so far as it goes; but especially O. Keller's 'Untersuchungen über die Geschichte der Griechischen Fabel,' in the *Jahrbücher für klassische Philologie* (1861-67); Hervieux, *Les Fabulistes Latins depuis le Siècle d'Auguste jusqu'à la fin du Moyen Âge* (1893 et seq.); the admirable chapter by Gaston Paris, in *La Littérature Française au Moyen Âge* (1888); and Plessow, *Fabeldichtung in England* ('Palæstra,' lii. 1906).

Fabliaux, a group of over a hundred compositions peculiar to the literature of France, consisting of metrical tales, usually satirical in quality, written in octosyllabic couplets, the epoch of the production of which covers about a century and a half. The oldest preserved appears to be *Richet* (about 1156); the greater number belong to the end of the 12th and the commencement of the 13th century; the most modern are those of Jean de Condé and of Watrquet, at the beginning of the 14th century. Society and literature then underwent a consider-

able change, and henceforward fabliaux proper disappear, being represented during the 15th century on one side by the prose tale, on the other by the farce, whence sprung in the fullness of time the modern novel and the comedy. Many of the French rhymed stories of the 12th and 13th centuries reappear later in the literature of other peoples, chiefly in Italy and England. It is certain that Boccaccio and Chaucer, for example, have sometimes imitated the French fabliaux, but this need not have been necessarily the case, as these stories circulated freely orally over all Europe, not to speak of their admission into sermons and books of edification.

Undoubtedly most of the stories were of oriental and especially Indian origin, many bearing distinctly the imprint of Buddhism, which has ever favoured the method of teaching by parable. These stories reached Europe by two main channels: from Byzantium, which received them from Syria or from Persia, whence they had been carried direct from India; and secondly, from the Arabs. The Arab importation took place at two widely different points: in Spain, largely by the mediation of the Jews; and in Syria, at the time of the Crusades. In Spain the transmission was mainly literary (through such media as the *Disciplina Clericalis*); in the East, on the contrary, the Crusaders, who lived in intimate contact with the Mussulman population, received many stories orally. Some of these being of Buddhistic origin were already moral and ascetic in character, and therefore easily Christianised; others, under cover of the final moral, related adventures that were dubious enough, but which were remembered while the tedious and not always relevant moral was forgotten; while others again were retained and transmitted simply for their wit. The fabliaux were, however, without exception, strangers to those great collections transmitted entire from one language to another; they spring from oral transmission and not from books. A few even are due to the native invention of their authors.

Their most general characteristic is their humorous and comic quality, too often involved in obscenity, and not infrequently falling into the most vapid platitude. Many of them are satirical, girding especially at certain classes, as villains and clerics, who are made the heroes of amorous adventures, now happy, now unhappy. A few are concerned with religion, and these are incongruous and irreverent enough. The fabliaux were not written for women, no doubt being usually recited by the *jongleurs* when the women had left the room; hence women are usually presented in the most unfavourable colours, whether as abandoned in character, or merely as peevish and jealous. They abound in gross sallies, the aim of which was but a moment's laugh; yet many are sweet little stories, very well told, and usually very moral or very sentimental. All have the great merit of painting the real life of their time; not at all of set purpose, but without effort they enable us to penetrate into the hearths of nobles, clergy, citizens, or peasants, and they speak to us in the familiar tongue of diverse classes of society in France about seven centuries ago. Their authors are seldom known. One or two names are Huon le Roi, author of *Vair Palefroi*; Jean Bedel, author of *Barat et Haimet*; Gautier le Long; Jacques de Baisieu; Henri d'Andeli; Ruste-beuf; Garin; Jean le Galois d'Aubepierre, author of *La Bourse pleine de sens*; and Jean de Condé.

See Montaiglon and Raynaud, *Recueil général et complet des Fabliaux des XIII^e et XIV^e Siècles* (6 vols. 1872-90); Gaston Paris, *Les Contes orientaux dans la Littérature Française du Moyen Âge* (1877), and *La Littérature Française au Moyen Âge* (1888); Bédier,

Les Fabliaux (1893); Petit de Julleville, *Littérature Française* (vol. II, 1896).

Fabre, FERDINAND (1830-98), born at Bédarieux, gained Sainte-Beuve's approval by *Les Courbezons*, followed by *Mon Oncle Célestin*, *L'Abbé Tigre*, and other novels.

Fabre, FRANÇOIS XAVIER PASCAL (1766-1837), born at Montpellier, was a pupil of David, painted portraits at Florence, and directed a school at Montpellier. He was believed to have privately married the Duchess of Albany, widow of Prince Charles Edward Stewart.

Fabre, JEAN HENRI (1823-1915), born at St Léons, Aveyron, was a schoolmaster and professor at colleges in Ajaccio and Avignon, and gave himself to close and imaginative observation of insects. His books, including many series of *Souvenirs entomologiques*, have been much read and translated. See his *Life by Legros* (Eng. trans. 1921), and Bicknell (1923). There is another *Life* by his brother, the Abbé Augustin Fabre (trans. 1921).

Fabre, MARIE JOSEPH VICTORIN (1785-1831), born in Ardèche, was a famous poet in his lifetime, but was soon forgotten.

Fabre d'Eglantine, PHILIPPE FRANÇOIS NAZAIRE (1755-94), an actor and dramatist, and a zealous revolutionist, was executed with his friends Desmoulins and Danton.

Fabretti, RAFFAELE (1618-1700), born at Urbino in 1618, became papal treasurer, chancellor to the papal embassy at Madrid, keeper of the papal archives, and wrote on the aqueducts of Rome, on the column of Trajan, and on ancient inscriptions.

Fabrizio, at the eastern base of the Apennines, 44 miles SW. of Ancona, has a cathedral and paper and parchment manufactories, and was the seat of the Fabrizio school of painting; pop. 25,000.

Fabrizio, GENTILE DA (1370-1450), was born at Fabrizio. His first teacher in art was, according to one account, Allegretto de Nuzio, according to another, Fra Angelico. His earliest work was perhaps the decoration of a chapel for Pandolfo Malatesta at Brescia. In 1423 he painted one of his best extant pictures, an 'Adoration of the Kings,' for the church of the Holy Trinity in Florence. Notable is also a Madonna with Saints (now in the Berlin Museum). A picture of the naval engagement between the fleet of Venice and that of the Emperor Barbarossa, painted for the Venetian senate, was destroyed by the fire at the ducal palace in 1574. Pope Martin V. employed Fabrizio, who had a childlike love of splendour and rich ornamentation, in adorning the church of St John Lateran with frescoes from the life of John the Baptist.

Fabricius, or FABRIZIO, GIROLAMO, commonly called *Acquapendente*, from the place of his birth, near Orvieto, a celebrated anatomist and surgeon, was born in 1537. He was the son of humble parents, who notwithstanding their poverty sent him to the university of Padua, where he studied anatomy and surgery under Fallopius. On the death of the latter in 1562 Fabricius was appointed to the vacant professorship, a post which he continued to hold for nearly half a century. Harvey, the discoverer of the circulation of the blood, was one of his pupils. Fabricius died at Padua, 21st May 1619. He was a laborious investigator, treated the eye, the larynx, the ear, the intestinal canal, the development of the foetus, and—his chief claim to remembrance—discovered the valves of the veins in 1574. See his *Opera Chirurgica* (1617).—**DAVID FABRICIUS** (1564-1603), was a pastor at Resterhaave and at Osteel in

East Friesland, and discovered several new stars.—His son, **JOANNES** (1587-1615), was a doctor of medicine, famous in astronomy as having discovered the spots on the sun (1610) and the sun's revolution.—**JOANNES ALBERTUS FABRICIUS** (1668-1738), bibliographer, was born at Leipzig, studied theology and philology there, but spent most of his life as teacher and rector in a gymnasium at Hamburg. He may be regarded as the modern founder of the history of classical literature and bibliography in virtue of his *Bibliotheca Latina* (3 vols. 1697), *Bibliotheca Græca* (14 vols. 1705-28), *Bibliotheca Latina Medice et Infimæ Aetatis* (5 vols. 1734-36), *Bibliographia Antiquaria* (1713), and *Bibliotheca Ecclesiastica* (1718). See the monograph by Reimarus (1737).—**JOHANNES CHRISTIAN FABRICIUS**, entomologist, was born at Tondeln in Sleswick, 7th January 1745, and died at Kiel, 3d March 1808. At Uppsala he worked under Linnæus, and in 1775 he was appointed to the chair of natural history at Kiel. His classification of insects, based upon the structure of the mouth, is expounded in his *Systema Entomologiae* (1775), *Genera Insectorum* (1776), *Philosophia Entomologica* (1778), *Mantissa Insectorum* (1787), and *Entomologia Systematica* (1792).

Fabroni, ANGELO, biographical writer, was born at Marradi in Tuscany, 26th September 1732, educated at Faenza and Rome, and in 1773 appointed tutor to the sons of Leopold, Grand-duke of Tuscany. He died 22d September 1803. His *Vite Italorum Doctrina Excellentium* (20 vols. 1778-1805) contains quite a treasure of information; while his *Laurentii Medice Vita* (2 vols. 1784) and *Vita Magni Cosmi Medice* (2 vols. 1788-89) were reckoned model biographies.

Fabyan, ROBERT, an English chronicler under Henry VII., was descended from an Essex family, and followed his father's trade as a clothier in London, where he was sheriff in 1493, and seems to have died in 1513. Three years later was printed by Pynson the first edition of his history, *The New Chronicles of England and France*. It begins with the arrival of Brutus, and comes down to the battle of Bosworth, reaching in its second edition (1533) the death of Henry VII. From the accession of Richard I. it takes the form of a London chronicle, and indeed the whole work has little value save for some points in the history of the city. The best edition is that by Ellis (1811).

Façade (Fr.), the exterior front or face of a building. This term, although frequently restricted to classic architecture, may be applied to the front elevation of a building in any style. It is, however, generally used with reference to buildings of some magnitude and pretensions; thus, we speak of the *front* of a house, and the *façade* of a palace. The back elevation of an important building is called the rear *façade*, and a side elevation the lateral *façade*. The sides of a court or cortile are also called *façades*, and are distinguished as north, south, &c. *façades*.

Facciolati, JACOPO, lexicographer, was born in 1682 at Torglia, near Padua, and educated in the religious seminary at Padua, where he subsequently became professor of Theology and rector. He held at the same time the chair of Logic in the university. Facciolati directed his attention chiefly to the revival of the study of ancient literature, and brought out (1715-19) a new edition of the *Lexicon Undecim Linguarum* or the *Calepine Lexicon*. In this work he was assisted by his pupil and brother-professor, EGIDIO FORCELLINI (1688-1768), to whom is mainly owing the conception of a totally new Latin dictionary. This Facciolati continued till his death on 27th August 1769, and it finally appeared in 1771 (new ed. by

De Vit, Prato, 1858-87; Eng. ed. 2 vols. 1826). Facciolati's Latin epistles and orations are remarkable for the Ciceronian purity and elegance of their style, and his remarks on Cicero's writings for their solidity, clearness, and taste. See *Lives* by Ferrari (1799) and Gennari (1818).

Facial Angle. See SKULL.

Facility, in the legal terminology of Scotland, is a condition of mental weakness short of idiocy, but such as makes a person easily imposed upon, and easily persuaded to do deeds to his own prejudice. The remedy is interdiction, which may be granted by the Court of Session of its own motion, or at the instance of the heir or next of kin of the facile person. This is judicial interdiction. When a person conscious of mental infirmity places himself under the control of trustees, the case is one of voluntary interdiction. This interdiction generally takes the form of a bond granted by the facile person to the persons therein named, who are called the interdictors. The object of interdiction is to prevent the facile person from granting deeds to his own prejudice, and after it has taken place he cannot contract without the consent of his interdictors. Even without interdiction the deeds of a facile person, if to his prejudice, may be set aside if there be proof of his having been circumvented or imposed on. There is no corresponding term in English law.

Fac-simile (Lat. *factum simile*, 'made like'), an exact copy, as of handwriting. See COPYING.

Factor, in its most general sense, is the term applied to any one who is employed to do business for another. In its most frequent use the name is applied to an Agent (q.v.) employed to sell goods consigned to him by his principal. His remuneration is called factorage or commission, and such an agent a commission-agent or consignee. A broker is also an agent of this kind, rewarded by a commission; but a factor differs from a broker in this, that a factor may buy and sell in his own name, and has the possession and apparent ownership of the goods consigned, and a lien over them. A factor is not entitled to delegate his powers, although he may employ a third person in any ministerial capacity which he cannot himself fulfil. The duty of a factor is to procure intelligence of the markets at his residence, of the course of exchange, and of the price of goods and the probability of a rise or fall; and to account to his principal for his transactions. A factor may pledge the goods of his principal for advances made upon the principal's account, or for the duties on the goods, but not for advances made upon the factor's account. The Factors Acts, the earliest of which was passed in the reign of George IV., enact that under certain circumstances factors having goods in their possession, or having possession of bills of lading, dock warrants, and similar documents referring to goods, shall be deemed owners of such goods, to the effect of giving validity to contracts with persons dealing *bona fide* on the faith of that ownership. Factory may be revoked, and falls by the death of the principal. The appointment of a new factor to do the same act implies revocation of the old factory. These general principles are common to both English and Scots law. In Scotland, however, the term is rarely used in that sense, and there are special uses not known in England—e.g. as applied to an agent managing heritable estates for another, letting farms, drawing rents, and the like, in which sense it is nearly synonymous with the English *steward*. In Scotland, too, the class of factors appointed by the courts for the management of the estates of persons under some incapacity, where the English courts appoint

receivers or trustees, has increased so largely in recent times as to call into existence a whole department of law dealing with their powers and duties. Such are called Judicial Factors.

Factor, in Mathematics. The numbers 6 and 4 multiplied together make 24; hence 6 and 4 are called *factors* of the product 24. All numbers except prime numbers are products of two or more factors; thus, $10 = 2 \times 5$; $12 = 3 \times 4$, or 2×6 , or $2 \times 2 \times 3$. Every product can be divided by any of its factors without remainder; a factor, therefore, is often called a *divisor*, or measure. 2, 3, 4, 6, 8, 12 are all factors or divisors of 24. Numbers that have no factor or divisor above unity, such as 2, 3, 5, 7, 11, . . . 23, &c., are called *prime* numbers. See NUMBERS (THEORY OF).

Factory and Workshop Acts.—The first germs of factory legislation in Great Britain are to be found in the attempts made to remedy the evils attendant on the employment of children, and, in particular, of pauper children in cotton-mills and factories. In the later years of the 18th century thousands of pauper children, in order to save the cost of their maintenance, were brought from their parishes and apprenticed in factories. Apprenticeship had always been regarded not merely as a period of service, but as a period of training; but the children apprenticed in the early factories were without opportunities of instruction. Moreover, the conditions under which they lived and worked were so demoralising as to be injurious to the community. In 1784 the Lancashire magistrates, influenced mainly by considerations of public health, passed a resolution that in future they would not allow 'indentures of parish apprentices whereby they shall be bound to owners of cotton-mills and other works in which children are obliged to work in the night or more than ten hours in the day.' This resolution is noteworthy as being the earliest attempt of any public body to limit the hours of children's labour. The condition of parish apprentices in factories also attracted the attention of parliament, for these pauper children were, in a true sense, wards of the state. In 1802 an act, which bore the title 'Health and Morals of Apprentices Act,' restricted the working hours for apprentices to twelve hours a day, and contained provisions for the cleansing and ventilation of cotton-mills and other factories, and for the clothing and education of apprentices employed therein. Nothing was done for the protection of factory children who were not parish apprentices till 1819, in which year an act, applying to cotton-mills only, prohibited the employment of children under nine years of age, and limited the working hours of children under sixteen years of age to twelve hours a day, exclusive of meal-times. By Lord Althorp's Act of 1833 the prohibition of the employment of children under nine years of age was extended to the textile trades generally, and a distinction, as regards hours of work, was made for the first time between children under thirteen years of age and 'young persons' from thirteen to eighteen years of age. The time of work for children under thirteen years of age was limited to nine hours, and for young persons to twelve hours. But the main importance of this act lay in its provisions for the creation of a staff of inspectors responsible to a central authority. The previous statutes had been rendered almost nugatory by the lack of administrative machinery for their enforcement; but the Act of 1833 was from the first vigorously enforced by inspectors, who were unaffected by local influences. Thenceforth, too, these inspectors rendered valuable service by collecting information which guided public opinion and prepared the way for subsequent legislation. The Act of 1844 is notable

in that it extended to adult women the same protection as had been provided for young persons, and introduced regulations for safety and the fencing of machinery. By the Act of 1847 the working hours of young persons and women were reduced to ten. The fact, however, that the act set no limits to the working day within which the ten hours might be worked opened the way to evasion. In particular, the adoption of systems of working in relays rendered it difficult for the inspectors to detect overtime employment. The risk of evasion by working in relays was brought to an end by the Acts of 1850 and 1853, which established for all protected persons a normal working day of ten and a half hours, extending from 6 A.M. to 6 P.M., with an allowance of an hour and a half for meals. The legal working day was thus made to coincide with the legal period of employment, allowance being made for meal-times. Up to this point the legislation had applied only to textile industries and a few others allied to them. But henceforth a movement set in for an extension of the principles of regulation to industries outwith the textile group, and by acts passed in 1864 and 1867 certain non-textile factories and workshops were brought within the sphere of state control. In 1875 the law as to factories and workshops had to be sought for in no fewer than nineteen statutes, and the varying statutory regulations applicable to different work-places and to different classes of workers created confusion. In that year the whole subject was considered by a Royal Commission, whose report, issued in 1876, led to the Factory and Workshop Act, 1878, which consolidated the law and removed many anomalies. Soon after the passing of this act further extensions of the law were found necessary. A series of acts made new and increasingly stringent provision for protecting the health and safety of persons employed in dangerous trades. In 1891 the age at which children might lawfully be employed was raised to eleven years. So numerous were the extensions and changes effected by the successive amending acts, that it became necessary again to consolidate the law on the subject. This was done by the Factory and Workshop Act, 1901 (1 Edw. VII. chap. 22). This act, with the extensions and alterations effected by subsequent statutes, forms the existing law, which now constitutes a great system of industrial control exercised by the state in the interests of the community.

The changes made in the law since the Act of 1901 have been in the direction of extending the operation of state control and rendering it more effective. The Notice of Accidents Act, 1906, has substituted a more stringent set of provisions as to the notification of accidents in factories and workshops. By the Factory and Workshop Act, 1907, laundries carried on by way of trade, or for the purpose of gain, or as auxiliary to another business, or incidentally to the purposes of a public institution, were brought under the general law applicable to non-textile factories and workshops, special regulations being made as to hours of work, sanitation, and ventilation. The Act of 1911 gave power to the Secretary of State to make regulations as to humidity and ventilation in cotton-cloth factories, and, in exercise of this power, elaborate regulations were issued in 1912. The volume of special orders and regulations for other dangerous trades, issued under the Act of 1901, has been constantly increasing. The Shops Act, 1912, which re-enacted and amended earlier acts, has provided for shop-assistants a system of protection as regards conditions and hours of employment similar in kind to that provided under the Factory Acts for workers in factories and workshops. The growing sense of public responsibility in regard to children has led to further

restrictions upon the employment of children, i.e. persons under fourteen years of age, imposed by the Employment of Children Act, 1903, and the Employment of Women, Young Persons and Children Act, 1920. The Education Acts of 1913 and 1921, extending the age for compulsory attendance at elementary schools, have also in effect raised the age at which children may be employed—it being expressly enacted by sect. 14 of the Act of 1918, which came into operation on 1st July 1922, that no child of school age shall be employed in any factory or workshop to which the Factory and Workshop Acts, 1901 to 1911, apply.

The Factory and Workshop Acts apply primarily to 'factories' and 'workshops.' Speaking generally, a place where a manufacturing process is carried on is a 'factory' if mechanical power is used, and a 'workshop' if mechanical power is not used. Some of the statutory provisions are also made applicable to docks, wharves, quays, and warehouses, to buildings in course of construction, and to railway lines or sidings used in connection with a factory or workshop.

Factories are either textile or non-textile. Textile industries are deemed to be more injurious to the health of the workers, and, accordingly, the regulations affecting textile factories, in particular as regards hours of labour, are more stringent than in non-textile factories. Thus overtime is not permitted in textile factories, but may be permitted in non-textile factories. Textile factories are places in which mechanical power is used to move or work machinery employed in preparing, manufacturing, or finishing cotton, wool, hair, silk, flax, hemp, jute, tow, china-grass, coconut fibre, or other like material, or in any process incident to the manufacture of such material. Certain works, however, in which such material is dealt with are declared not to be textile factories, viz. print-works, bleaching and dye works, lace warehouses, paper-mills, flax-scutch-mills, rope-works, and hat-works. Non-textile factories consist of (a) the premises mentioned in Part I. of the sixth schedule of the Act of 1901, whether mechanical power is used or not—a lengthy list, including print-works, bleaching and dye works, earthenware-works, blast-furnaces, foundries, metal and india-rubber works, paper-mills, glass-works, tobacco-factories, bookbinding-works, electrical stations; (b) the premises mentioned in Part II. of that schedule provided that mechanical power is used—the list including hat-works, rope-works, bakehouses, lace warehouses, shipbuilding yards, quarries, dry-cleaning, carpet-beating, and bottle-washing works, and now also, under sect. 1 of the Act of 1907, laundries; and (c) all premises in which any manual labour is exercised by way of trade or for purposes of gain in a manufacturing process, provided that mechanical power is used in aid of the manufacturing process there carried on. 'Domestic factories'—that is, private houses or rooms which, though used as dwellings, are, by reason of the work carried on there, factories, in which no mechanical power is used and the only persons employed are members of the same family dwelling there—are subject to special regulations and exemptions as regards hours of labour, sanitation, ventilation, meals, holidays, accidents, and registration. Special regulations are also made for 'tenement factories,' that is, buildings containing separate factories which are occupied by different persons and supplied with mechanical power from the same source. The owner of a tenement factory (whether or not he is one of the occupiers) is, instead of the occupiers of the separate factories, responsible for the cleanliness and sanitary condition of the whole building, for the fencing of all machinery not supplied by the occupiers, and

for the affixing of notices with respect to the employment of children.

Workshops are premises which, if mechanical power were used; would be non-textile factories of class (b) or class (c) above mentioned, provided, in the case of class (c), that the employer of the persons working therein has the right of access or control. Workshops generally are subject to the same regulations as non-textile factories in respect of hours of employment. The supervision of the sanitary condition of workshops lies in the first instance with the local authority, not, as in factories, with the factory inspector; but the inspector may intervene in the event of the local authority neglecting to perform its duties. Special regulations are made for four classes of workshops: (1) 'men's workshops,' that is, workshops conducted on the system of not employing any woman, young person, or child; (2) 'women's workshops,' that is, workshops conducted on the system of not employing either children or young persons; (3) 'domestic workshops,' that is, private houses or rooms which, by reason of the work carried on there, are workshops, in which no mechanical power is used and the only persons employed are members of the same family living there; and (4) 'tenement workshops,' that is, premises in which, with the permission of or under agreement with the owner or occupier, two or more persons carry on any work which would constitute the premises a workshop if the persons working there were in the employment of the owner or occupier.

The statutory provisions fall into two main groups. The *first* group deals with matters affecting health and safety, such as cleanliness and ventilation, fencing of machinery, means of escape in case of fire, notice of accidents, and regulations for dangerous trades. These general provisions relating to health and safety are designed for the protection of all classes of workers, including adult men. The *second* group defines hours of employment, makes provision for meal-times and holidays, and lays down special regulations as to conditions of work. The provisions in this group do not, speaking generally, apply to adult men, but are designed for the protection of women (i.e. females of eighteen years and upwards), young persons (i.e. persons from fourteen to eighteen), and children (i.e. persons under fourteen). In addition to the provisions falling under these two main groups, the acts contain important provisions with respect to home-work and out-workers, the particulars of work and wages to be furnished to piece-workers, administration and inspection, and other incidental and supplementary matters.

Factories and workshops must be kept clean and free from effluvia. They must be ventilated so as to render harmless, as far as practicable, all gases, vapours, dust, or other impurities, generated in the course of the work, that may be injurious to health. In every room sufficient means of ventilation must be provided. Where the process carried on generates dust, gas, vapour, or other impurity, which is inhaled by the workers to an injurious extent, an inspector may require a fan or other mechanical means of ventilation to be supplied. Provision is made against overcrowding. A minimum space of 250 cubic feet is required for each person employed at one time in any room; but during any period of overtime, and in certain other circumstances, the proportion is fixed at 400 cubic feet. A reasonable temperature must be maintained in each room in which any person is employed, floors liable to be wet must be drained, and separate and suitable sanitary conveniences must be provided for workers of both sexes. Special regulations for the protec-

tion of health are made in the Act of 1901 with respect to bakehouses and certain other classes of premises and industries. The Act of 1907 contains special provisions as to the ventilation, temperature, and drainage of, and the periods of employment in, laundries. The Act of 1911 and the regulations made under that act lay down elaborate rules as to humidity and ventilation in cotton-cloth factories.

The Police, Factories, &c., Act, 1916, provides that a factory or workshop is not deemed to be kept in conformity with the acts if the occupier does not comply with orders of the Secretary of State relative to arrangements for preparing or heating and taking meals, the supply of drinking-water, the supply of protective clothing, ambulances and first-aid arrangements, the supply and use of seats in workrooms, facilities for washing, accommodation for clothing, and arrangements for supervision.

The provisions as to safety enact that hoists, fly-wheels, and all dangerous machinery must be securely fenced; that steam boilers are to be maintained in proper condition and examined by a competent person at least once in every fourteen months; and that means of escape in case of fire shall be provided and maintained in good condition and free from obstruction. Restrictions are placed on the cleaning of machinery while in motion. A child must not be allowed to clean any part of any machinery, or any place under any machinery (other than overhead mill-gearing), while the machinery is in motion. A young person must not be allowed to clean any dangerous part of the machinery while the machinery as a whole is in motion, even though the actual part being cleaned is at rest. No prohibition is put on the cleaning by women of the manufacturing parts of the machinery; but neither women nor young persons are to be allowed to clean the mill-gearing (which includes all shafts, wheels, and other appliances by which power is transmitted) while the machinery is in motion.

Accidents in a factory or workshop causing death or disablement for specified periods must, under the Notice of Accidents Act, 1906, be notified forthwith to the inspector of the district, and also, in some cases, to the certifying surgeon. The occupier must keep a register of all accidents of which notice is required to be given to an inspector. Dangerous trades are specially regulated by direct statutory provisions and by special regulations made by the Secretary of State. When any case of lead, phosphorus, arsenical, or mercurial poisoning, or any case of anthrax or toxic jaundice occurs in a factory or workshop, the occupier must at once send written notice to the inspector and to the certifying surgeon. In any factory where lead, arsenic, or any other poisonous substance is used, suitable washing conveniences must be provided. Prohibitions are put on the taking of meals in rooms where such poisonous substances are so used as to give rise to dust or fumes, and in factories and workshops, or parts thereof, in which the nature of the process carried on renders the taking of meals therein specially injurious to health. In a factory where wet-spinning is carried on the employment of women, young persons, and children is only permitted under prescribed conditions. There are also direct statutory provisions prohibiting the employment of girls under sixteen years in the making or finishing of bricks and tiles (not being ornamental tiles), or the making and finishing of salt; of children and young persons in the making of white lead or the mercurial silvering of mirrors; of children in any dry-grinding in the metal trade or the dipping of lucifer matches; and of children and female young persons in the melting

or annealing of glass. In addition to these direct statutory provisions, power is conferred on the Home Secretary, when he is satisfied that any manufacture or process is dangerous or injurious to health or dangerous to life or limb, either generally or in the case of women, children, or any other class of persons, to certify that manufacture or process to be dangerous, and thereupon to make regulations for the safety of persons employed therein. This general power has been freely exercised, and a great mass of orders and regulations has been issued imposing special conditions upon employment in trades and processes which have been certified to be dangerous.

The Factory and Workshop Act, 1901, enacts that a child under the age of twelve years shall not be employed in a factory or workshop, and makes minute regulations as to hours of employment, meal-times, holidays, and overtime work for (1) children—'child' being defined as a person who is under the age of fourteen years and who has not, being of the age of thirteen years, obtained an educational certificate; (2) young persons—'young person' being defined as a person who has ceased to be a child and is under the age of eighteen years; and (3) women of the age of eighteen years and upwards. The rules as to hours and conditions of work for these several classes of workers vary according to the type of factory or workshop in which the worker is employed. In textile factories overtime is not permitted to be worked by women, young persons, or children. In those non-textile factories and workshops in which overtime employment of women and young persons is permitted, stringent conditions are imposed upon such overtime work. Overtime employment of children is permitted only in specified non-textile factories and workshops, and is permitted there only for an extra period not exceeding thirty minutes in order to complete an incomplete process. No woman or girl may be employed in a factory or workshop within four weeks after child-birth. No child, young person, or woman may be employed in a factory or workshop on Sunday except in the case where both employer and employed are of the Jewish religion and the premises of the occupier have been closed during the whole of Saturday. The Employment of Children Act, 1903—amended, as regards England and Wales, by sect. 92 of the Education Act, 1921, re-enacting sect. 13 of the Education Act, 1918, and, as regards Scotland, by sect. 16 of the Education (Scotland) Act, 1918—imposes important general restrictions on the employment of children, and enacts that no child who is employed half-time under the Factory and Workshop Act, 1901, shall be employed in any other occupation. The Women, Young Persons, and Children Employment Act, 1920, which became operative on 1st January 1921, provides that no child under the age of fourteen years shall be employed in any industrial undertaking (except an undertaking in which only members of the same family are employed). The term 'industrial undertaking,' in this relation, is defined as including mines and quarries; industries in which articles are manufactured, altered, cleaned, repaired, or in which materials are transformed; the construction, maintenance, repair, or alteration of any building, railway, tramway, dock, road, electrical undertaking, gas-work, or other work of construction; and transport by road or rail or inland waterway, including the handling of goods at docks, wharves, and warehouses, but excluding transport by hand. This act also contains provisions relating to the employment of young persons, i.e. persons between fourteen and eighteen, and of women. In particular, it provides that no young person or woman shall be employed at night in

any industrial undertaking except to the extent to which, and in the circumstances in which, such employment is permitted under the convention adopted by a general conference of the International Labour Organisation of the League of Nations, and set out in a schedule to the act.

The provisions (sects. 68-72) of the Factory and Workshop Act, 1901, relating to the education of children have been repealed by the Education Act, 1918. As regards England and Wales, the extant statutory law with respect to compulsory attendance at elementary schools and continuation schools is now embodied in the Education Act, 1921. A local education authority administers, under the general supervision of the Home Office, the law relating to the employment of children and young persons, and has wide powers of making and enforcing by-laws upon this subject. Sect. 14 of the Education Act, 1918—which came into operation on 1st July 1922 (the appointed day), and is not repealed by the Education Act, 1921—enacts that no child within the meaning of the act shall be employed in any factory or workshop to which the Factory and Workshop Acts, 1901 to 1911, apply, unless lawfully so employed on the appointed day. The word 'child' in the act means a child of any age up to the age when his parents cease to be under an obligation to cause him to receive efficient elementary education or to attend school; that is to say, up to the end of the school term in which he attains the age of fourteen years, unless, under sect. 46 (2) of the Education Act, 1921, the age of fifteen years has been fixed by by-law. For other statutory provisions with respect to compulsory education and the conditions on which children of school age may be employed in factories and workshops or elsewhere, see EDUCATION.

The occupier of a factory or workshop is directed to notify the inspector of such occupation; to fix up in the works an abstract of the act and certain other information; and to keep a register of various particulars as to employment, health, and accidents. Lists of out-workers must be kept in certain trades, and work is prohibited in premises which are unwholesome or in which there is infectious disease. The occupier of a textile factory is required to furnish particulars of the rate of wages applicable to the work to be done, and also particulars of the work to which that rate is to be applied, in order that piece-workers may compute the due amount of wages payable to them in respect of their work. The Secretary of State is empowered to extend this requirement to non-textile factories and workshops, and this has been done by a series of orders.

Inspectors, male and female, are appointed by the Home Secretary, and are furnished with certificates of their appointment, which must, if required, be produced on applying for admission to a factory or workshop. The inspectors are authorised to enter and inspect, at all reasonable times, by day and night, all parts of a factory or workshop; to require the production of registers, certificates, and other documents kept in pursuance of the acts; to make such examination and inquiry as may be necessary to ascertain whether the requirements of the Factory Acts and Public Health Acts are being complied with; to prosecute, conduct, or defend in courts of justice any proceeding arising under the acts; and to exercise such other powers as may be necessary for carrying the acts into effect. See also SHOPS ACT, TRUCK ACTS, PUBLIC HEALTH ACTS, TRADE BOARDS.

Faculæ (Lat. *facula*, 'a torch'), brighter spots sometimes seen on the sun's disc. See SUN.

Faculty, a name formerly applied by philosophers (Reid, Hamilton, &c.) to each of the primary or fundamental powers or functions of the mind. But the view on which this nomenclature was based is rapidly becoming obsolete. According to modern psychology, the mind is a unity, and the so-called faculties are the different specific directions or modes in which its energy works. See PSYCHOLOGY. For the faculty of a university, see UNIVERSITY.

A Grant of Faculty by the Ordinary is an order by the bishop of a diocese to award some privilege not permitted by common law. A faculty is necessary in order to effect any important alteration in a church, such as the erection of a gallery or of an organ. Without a faculty, a person is not entitled to erect a monument within the walls of a church. —*The Court of Faculties* is a court established by Henry VIII., whereby authority is given to the Archbishop of Canterbury and his successors to grant dispensations and faculties, an authority formerly pertaining to the pope. The sittings of the court have always been held at Doctors' Commons (q.v.). Of late years the court has been chiefly occupied with granting licenses to marry without publication of banns. See ECCLESIASTICAL COURTS, MARRIAGE, DISPENSATION.

Fæces, the solid excrements, the matters which an animal ejects from the lower end of the intestinal canal, and in greater part consisting of those portions of food which, on passing through the alimentary canal, have been rejected as comparatively worthless in the office of nutrition. In the higher animals the fæces generally contain about three-fourths of their weight of water, the remaining one-fourth consisting in greater part of organic remains; in the case of the ox, sheep, and other herbivorous animals, of undigested woody fibre. See DIGESTION, MANURE.

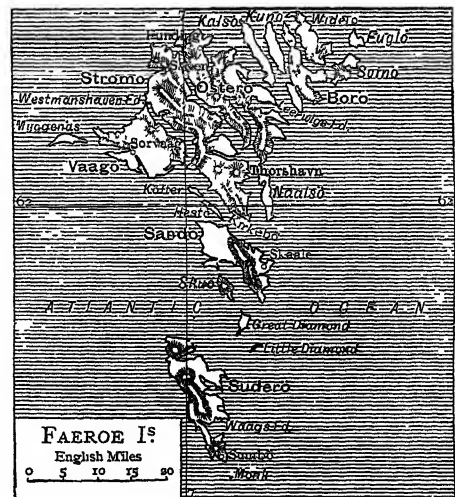

Fæd, JOHN, a Scottish painter, was born in 1820 at Burley Mill, near Gatehouse-of-Fleet, Kirkcudbrightshire, where his father was an engineer and millwright. His love of art was manifested at an early period, and when hardly entered on his teens he was in the habit of making tours through the villages of Galloway, painting miniatures. In 1841 he went to Edinburgh, where his talents ultimately won recognition; and he was elected an A.R.S.A. in 1847, an R.S.A. in 1851 (he resigned in 1896). He settled in Gatehouse-of-Fleet in 1880, and he died 22d October 1902. His first popular picture was 'The Cruel Sisters' (1851). Other works were, besides landscapes, 'Shakespeare and his Contemporaries,' 'The Cotter's Saturday Night,' and, after settling in London in 1864, 'The Wapenschaw,' 'Tam o' Shanter,' 'Haddon Hall of Old,' 'The Stirrup Cup,' 'John Anderson my Jo,' and 'The Hiring Fair.'

Fæd, THOMAS, R.A., brother of the preceding, was born at Burley Mill, 8th June 1826, and in 1842 began his regular art studies in Edinburgh. At the Trustees' Academy he took several prizes; the first picture he exhibited was a water-colour of an incident from the *Old English Baron*. Shortly after, he discovered his true strength in 'Reading the Bible,' a simple subject from Scottish peasant life, and he was made an Associate of the Royal Scottish Academy in 1849, in which year he produced an interesting work entitled 'Scott and his Friends at Abbotsford,' which was engraved by his brother James Fæd. In 1852 he removed to London, where his 'Mitherless Bairn,' exhibited in 1855,

a popular and taking composition, was declared by some critics to be 'the picture of the season.' Of his subsequent works we need mention only 'Home and the Homeless,' 'The First Break in the Family,' 'Sunday in the Backwoods,' 'From Dawn to Sunset,' 'Baith Faithier and Mither,' and 'The Last o' the Clan.' Fæd was made A.R.A. in 1859, R.A. in 1864, and an honorary member of the Vienna Academy in 1875. He died in August 1900.

Faenza, a town of Italy, 31 miles SE. of Bologna by rail, has an imposing cathedral, a fine market-place surrounded with arcades and adorned with a fountain, and numerous palaces and ecclesiastical edifices. Its manufacture of glazed and coloured earthenware vessels, in Italy called 'majolica,' and in France 'faience,' has declined in importance. Its chief industries are cotton-spinning, tanning, and the making of pottery, furniture, and carriages. Pop. 45,000. Faenza, the ancient *Faventia*, at one period a town of the Boii, and afterwards a *municipium* under the Romans, fell under the power of the Manfredi family; in 1509 it was captured by Pope Julius II.

Faeroe Islands (Dan. *Færoerne*; Færoese, *Foroyar*, 'sheep islands'), a Danish group of islands, twenty-two in number, of which eighteen are inhabited, lying between the Shetlands and Iceland, 200 miles NW. of the former, in 61° 25'—62° 25' N. lat., and 6° 19'—7° 40' W. long. Their area is 513 sq. m., and their population (1850) 9150; (1901) 15,230; (1921) 21,364. The islands are the remains of a single continuous plateau, originally trenched by deep erosion valleys, which, being submerged by the sea during a subsequent era of depression of the land, became converted into fjords and sounds. Geologically they consist of volcanic rocks, horizontally disposed beds

of basalt predominating. Seaward they present rugged precipitous cliffs, ranging in height from 1000 to 2300 feet, whilst inland they rise into flat-topped pyramidal mountains, which attain maximum elevations of 2502 feet in Skellingfield in Streymoy, and of 2895 feet in Slattareitind in Eysturoy. The elements that run through the sounds are swift and dangerous; storms and whirlwinds are frequent; and the harbours and anchorages in the fjords and bays are not yet very secure, but, on the other hand, nearly always free from ice. For, though the climate is misty and moist, the winters are comparatively mild. Peat and coal are used for fuel. Trees there are none, owing to the storms; timber

for building purposes is imported from Norway. Tillage is confined to the cultivation of a few vegetables, and attempts, not always successful, to grow barley. The principal sources of wealth are sheep-farming, wild-fowling, and fishing; and the products of these, including wool, feathers, salt and dried fish, whale products, guano, and skins, are the principal exports, sent for the most part to Denmark. The largest islands are Stroma (28 miles long by 8 broad), Östero, Vaago, Sando, and Sudeö. The capital of the group is Thorshavn in Stroma, with 2500 inhabitants; the town of Kirkebo, on the same island, was formerly the seat of a bishop. The inhabitants, of Norse descent, mixed with a darker element (indigenous, Irish, or Hebridean perhaps), are simple and grave in their manners, and industrious in their habits. They speak an Old Norse dialect, though modern Danish is the language of law-courts, churches, and schools. They belong to the Lutheran Church. Since 1854 the islanders have enjoyed a certain amount of self-government. The elected Lagting elects a representative to the Danish Landsting, and the people elect a representative to the Folketing. From the time of their first colonisation in the 9th century the Faeroe Islands belonged to Norway down to 1380, in which year they passed to Denmark. The natives possess a number of ancient epical ballads (*kvaði*), the most important group being the *Sjárðar Kvaði*, or songs of Sigurd (ed. with grammar, glossary, &c. by Max Vogler, i. Paderborn, 1877). The chief names in the native literature are Svabo (1746-1824); N. Mohr (1742-90); J. H. Schröter (1771-1851), the first to devote much attention to the prose literature—some of the folk-stories he collected are to be found in *Antiquarisk Tidsskrift* (1849-51); the patriotic Poul Nolsø (1766-1809), whose *Vogellied* is the most popular modern poem in the Faeroe dialect; and Venzel Ulrik Hammershamb, editor of *Færøiske Kvæder* (1851-55).

There is a grammar (1854) by Hammershamb, who also translated into modern dialect the so-called *Færeyingasaga*. See Hammershamb and Jacobsen's *Færøisk Anthologi* (Copenhagen, 1891); Jeaffreson's *The Faeroe Islands* (1898); Annandale's *The Faeroes and Iceland* (1905); *The Botany of the Faeroes*, by Warming and others (trans. 1909); French works by Leclercq (1833) and Labonne (1885).

Fagging, a usage in the great public schools of England, in virtue of which the senior boys are authorised to exact a variety of services from the junior boys. A lower form boy has certain duties to perform to all the upper form boys, as in stopping the balls for them when practising cricket—and others which he owes to a special master, such as stoking his fire and carrying his messages, of a more or less private kind. The risk of capricious exercise of the senior boys' privileges in harassing or humiliating the juniors is sufficiently obvious; but, on the other hand, the system is said by its defenders to make boys handy, helpful, and docile, while taking the nonsense out of bump-tious lads. And the argument chiefly relied on in its favour is that the relation thus established between seniors and juniors prevents bullying. The origin of the usage, which is prominent in tales of school-life, such as *Tom Brown's School-days*, is sought for in the necessity felt in great boarding-schools for a scheme of definite relations amongst the boys, so as to secure definite rights and immunities during the time when they are not in the teacher's presence. A similar usage, called *Pennalism*, sprang up in the German universities in the 17th century; and the freedoms taken, under the name of *hazing*, by sophomore and senior students with freshmen in the American colleges is somewhat analogous.

Faggot-votes, votes manufactured, chiefly for county elections, by the nominal sale of property, under mortgage or otherwise, so as to qualify the holder to vote. The extension of the county franchise left faggot-votes practically no longer worth the trouble of procuring. The term *faggot* described formerly a person who was hired to fill up another's place at the muster of a regiment, or to conceal a deficiency in its strength.

Fagotto. See BASSOON

Faguet, ÉMILE, French critic and man of letters, was born at La Roche Sur Yon, 17th December 1847, and educated at the École Normale in Paris. He taught at La Rochelle and Bordeaux, and from 1890 was professor of literature at the Sorbonne. In 1900 he was elected to the Académie. He died 7th June 1916. He wrote a history of French literature and numerous monographs, besides dramatic criticisms.

Fahln. See FALUN.

Fahrenheit, GABRIEL DANIEL, the improver of the thermometer and barometer, was born at Danzig, 14th May 1686. He was originally destined for a commercial career, but he early abandoned trade for natural philosophy, and, after travelling through Germany and England, settled in Holland. About 1714 he conceived the idea of using quicksilver instead of spirits of wine in the construction of thermometers, by means of which the accuracy of the instrument was very much improved. For his determination of his zero, freezing-point, &c. see THERMOMETER. He fixed his freezing-point at 32° to avoid negative measurements. In 1724 Fahrenheit was elected a Fellow of the Royal Society of London; and the *Philosophical Transactions* of that year contain several papers by him on points in natural philosophy. He died 16th September 1736.

Fa-hsien, a Chinese Buddhist monk and traveller of the beginning of the 5th century A.D., made a pilgrimage from Si-ngan-fu by the Gobi Desert, Khotan, and Hindu Kush, to India, where he spent many years in visiting the scenes of the Buddha's life, and thence to Ceylon, where he copied manuscripts. His book was translated by Giles (1877; revised 1923).

Faidherbe, LOUIS LÉON CÉSAR, French general, was born at Lille on 3d June 1818. His apprenticeship as a soldier was passed in Algiers and Guadeloupe. His activity as a seasoned soldier connects him with the history of the French colony of Senegal, and with the Franco-German war of 1870-71. Proceeding to Senegal in 1852, he became two years later governor of the colony, and in that capacity not only reduced to complete submission several more or less tributary tribes, but also extended the frontiers of the colony by the subjugation of the Moorish Trarza in 1858, and of the country of Cayor in 1861. Under the dictatorship of Gambetta, Faidherbe was summoned to France in December 1870, and given command of the army of the North. After successfully withstanding Manteuffel's attack near the river Hallue, 23d December, he was severely beaten near St Quentin on 19th January 1871. After the conclusion of peace, he was despatched by the French government to Upper Egypt to study the monuments. He died at Paris, 28th September 1889. Faidherbe published useful books on the languages, geography, and archæology of northern Africa, chief amongst which are two collections of *Numidian Inscriptions* (1870-72), *Anthropology of Algiers* (1874), *Épigraphie Phénicienne* (1873), *Le Soudan Français* (1884), a work on *Senegal* (1889), and treatises on the *Poul Language* (1875) and the *Berber Language* (1877). His

Campagne de l'Armée du Nord appeared at Paris in 1871.

Faience, or FAYENCE. See FAENZA.

Fainéants Rois (taken to mean the 'Do-nothing Kings,' though *fainéant* is really *fainçant*, 'sluggard,' participle of Old French *faindre*, 'to shirk,' 'to feign'), the sarcastic designation of the later Merovingian sovereigns of France, under whom the famous Mayors of the Palace really governed the country. The first of the series was Thierry III., nominally monarch of Burgundy, Neustria, and Austria (i.e. Austrasia); the others were Clovis III., Childebert III., Dagobert III., Chilperic II., Thierry IV., and Childeric III. The last of these was dethroned in 730 by Pepin *le Bref*, Mayor of the Palace, who caused himself to be formally proclaimed king. Louis V., the last of the Carolingians, and a descendant of Pepin *le Bref*, also received the epithet of *Fainéant*.

Fainting, or SYNCOPE (Gr.), is a condition in which, owing to a sudden mental or bodily impression, the circulation of blood is temporarily arrested or very much diminished in force and volume, the respiration and the functions of the nervous system being likewise suspended. The indications of fainting to a bystander are chiefly a sudden pallor, accompanied by loss of power over the limbs, with disappearance of the pulse and movements of respiration; the eyes are commonly half-open or closed, the countenance bloodless, but quite at rest, and not indicative of suffering or disturbance: the flaccid, motionless condition of all the limbs also tends to distinguish simple fainting from epilepsy and the other diseases attended with spasm; whilst the vanishing of the colour and the suppression of the pulse make a marked distinction between fainting and Catalepsy (q.v.) and other forms of Hysteria (q.v.); with which disorders, however, fainting may in some cases be associated. Minor degrees of fainting, where there is no more than a feeling of faintness and a little pallor, are also common. The mode and origin of fainting and the study of its phenomena alike lead to the conclusion that it is primarily an impression upon the nervous system, very much of the same nature as the Collapse, or shock of a severe bodily injury; this reacts, in the first instance, on the heart, and through the circulation on all the other functions of the body. Fainting may end in death, if too prolonged, or if associated with disease of the internal organs, and especially of the heart. See HEART (DISEASES OF THE). Ordinarily, a person who faints from mental emotion, a hot and close atmosphere, or other transient cause, is readily restored by being laid on the back with the head low, and allowed plenty of cool, fresh air. If the patient is or can easily be placed in a sitting posture, he is often still more quickly brought round by making him bend forward with the head between the knees. The worst possible treatment is to raise him or hold him up, the course nevertheless instinctively adopted by almost every one. Any tight articles of dress should be loosened, and a stream of cold air, or a little cold water, should be directed to the face and neck, so as to arouse the respiratory movements. It is desirable, also, to apply ammonia or aromatic vinegar to the nostrils; but a more effective way of exciting the respiration is to compress the ribs and allow them to expand again, so as to imitate the natural movement. A little alcohol or sal volatile should be administered if the patient can swallow. Care should be taken to ascertain that there is no obstruction in the throat or air-passages, as suffocation from mechanical causes has been mistaken for fainting, and the real origin of the mischief overlooked, with fatal con-

sequences. For some time after coming out of the faint, the person should remain recumbent and quiet till the heart's action is fully restored.

Fairbairn, ANDREW MARTIN (1839-1912), was born at Inverkeithing, studied at Edinburgh University, and after the requisite theological training became pastor of an Evangelical Union church at Bathgate, from which he obtained leave of absence to pursue his studies in Germany. After his return he preached in Aberdeen until his able theological writings earned him in 1878 the principalship of the Airedale Congregational College at Bradford. In the same year he was made D.D. by his own university, and in 1881-83 he was Muir lecturer there on comparative religions. His brilliant and learned essays in the *Contemporary Review* early attracted attention, and his *Studies in the Philosophy of Religion and History* (1876), *Studies in the Life of Christ* (1880), *Christianity in the First and Nineteenth Centuries* (1883), *The City of God* (1883), *Religion in History and in the Life of To-day* (1884), *The Place of Christ in Modern Theology* (1893), *Catholicism, Roman and Anglican* (1899), and *The Philosophy of the Christian Religion* (1902) secured him a place amongst leading theologians. In 1888-1909 he was principal of Mansfield College (Congregationalist) at Oxford. See Life by W. B. Selbie (1914).

Fairbairn, SIR WILLIAM, engineer, was born at Kelso, 19th February 1789. He was apprenticed (1804) to an engine-wright in a colliery at North Shields, where he studied mathematics, and made acquaintance with George Stephenson. In Manchester (1817) he took a lead in making iron boats; and his works at Millwall, London (1835-49), turned out hundreds of vessels. For the Menai tubular bridge (Robert Stephenson's idea) Fairbairn invented the rectangular tube ultimately adopted (see BRIDGE); and he erected a thousand bridges upon this principle. He aided Joule and Thomson (Lord Kelvin) in 1851 in investigations, and guided the experiments of the government committee (1861-65) on the use of iron for defensive purposes. A chevalier of the Legion of Honour, he was created a baronet in 1869. He died at Moor Park, Surrey, 18th August 1874. See his Autobiography (1877).

Fairfax, EDWARD, the translator of Tasso's *Jerusalem Delivered*, was a son (perhaps a natural son) of Sir Thomas Fairfax of Denton, in Yorkshire. The year of his birth is not known, but is believed to have been about 1580. His life was spent quietly, in literary pursuits, at Fewston, near Otley, where he died in Jan. 1635. His translation of *Gerusalemme Liberata* (1600; new ed. 1890) was dedicated to Queen Elizabeth. For poetical beauty and freedom it has been the theme of universal praise. Dryden ranked Fairfax with Spenser as a master of English, and Waller said that he derived from him the harmony of his numbers. Hallam, much less enthusiastic, says that it lacks the grace of the original, though not wanting in spirit and vigour. Fairfax also wrote a *Discourse of Witchcraft* (1621), describing how two of his own daughters were bewitched. It was published by Monckton Milnes in the *Miscellanies* of the Philobiblon Society (1858-59).

Fairfax, THOMAS, LORD, generally known as Sir Thomas Fairfax, parliamentary general, was the son of Ferdinando, Lord Fairfax, and was born January 17, 1612, at Denton, Yorkshire. He studied at St John's College, Cambridge, and from 1629 served as a volunteer in Holland,

under Lord Vere, whose fourth daughter, Anne, he married (1637) shortly after his return to England. On the outbreak of the Civil War in 1642 Fairfax espoused the cause of the Parliament, and was appointed general of horse under his father, who commanded the parliamentary forces in the north. He distinguished himself so much by his valour, prudence, and energy, especially at Marston Moor (1644), where he was wounded, that in 1645, when the Earl of Essex resigned the office of general of the parliamentary forces, Fairfax was appointed to the supreme command; but the real ruling genius of the army was Cromwell, who had risen to be lieutenant-general. In June 1650, on Fairfax's refusal to march against the Scots, who had proclaimed Charles II. king, Cromwell was appointed commander-in-chief in his stead. Fairfax now withdrew into private life. After the death of Cromwell he laboured for the restoration of the king, and gathered troops to assist General Monk against Lambert. He was appointed head of the commission despatched to the Hague in 1660 to arrange for the return of Charles II. He died at Nunappleton, Yorkshire, 12th November 1671. Fairfax wrote several works, prose and poetic, including two memoirs on the Civil War. See his *Correspondence* (4 vols. 1848-49), and a *Life* by C. R. Markham (1870).

Fairford, a village of Gloucestershire, 9 miles E. of Cirencester, and 26 WSW. of Oxford. Its fine Perpendicular church, built by John Tame in the 15th century, is famous for its splendid series of twenty-eight stained-glass windows, often erroneously attributed to Albert Durer, but really of Flemish workmanship. Keble was a native. See the Rev. J. G. Joyce, *The Fairford Windows* (fol. 1872).

Fair Head, or BENMORE, a precipitous promontory of the north coast of Antrim, Ireland, opposite Rathlin Isle, which is 4 miles to the NW. It rises 636 feet above the sea, and consists of Carboniferous strata, overlaid by greenstone columns, 20 to 30 feet thick, and 280 to 300 feet high.

Fairies, Elves, supernatural beings, generally of human form but diminutive size, a belief in whom has been among the superstitions of the greater portion of the European nations. The word *elf* is from the Anglo-Saxon *ælf*, which corresponds to the Danish *alf*, the Icelandic *álfr*, and the German *alp*; but the Germans adopted in the 17th century *elf* and *elke*, from the English for the same idea. Fairy is properly enchantment, or the realm of fairy spirits, *fay* being originally the name of the sprites themselves. *Fay* (Low Lat. *fata*, 'fairy'; Fr. *fée*) is from Lat. *fatum*, 'fate,' and once meant the goddess of destiny. From the Old French *fée* (= *fée*) comes *faerie*, 'enchantment;' whence fairy. The Celtic *fées* or fairies are undoubtedly relics of those *matres* and *matronæ* which appear on Gallo-Roman inscriptions as objects of popular belief. After the transfusion of the Teutonic and southern nations the northern elves (which were originally of two kinds—the light elves, or elves proper, and the dark elves, or dwarfs) became mixed up with their Celtic kindred, the fairies, in inextricable confusion.

Tracing back the antecedent history of this widespread belief, various fanciful theories have been suggested to explain its origin and growth; most of which cannot be accepted as satisfactory. But, like many other survivals of superstition, it is probably to be connected with the mythological conceptions of the Greeks and Romans; some folklorists referring the fairy to the *Parcæ* or Fates of primitive times, who were supposed to rule the destiny of man. The long occupation of Gaul by the Romans familiarised its natives with their

mythological conceptions of nymphs and fauns, and indeed these closely resemble in many particulars the famous fays of the medieval romances. Again, the native Gauls themselves had a large pantheon of topical divinities, and doubtless these became fused with the other traditional figures, whether due to creative imagination or to more or less direct transmission, and thus helped to create the composite product forming the fairydom of our folklore, which through such literary mediums as the work of Straparola and the *Pentamerone* of Basil has exercised a profound influence upon western Europe. Fairies in literature have received the most different treatment: thus, Boiardo's, Ariosto's, and Spenser's fairies are mere diminutive men, with all the ordinary human emotions, while in the Oberon and Titania of Shakespeare's *Midsummer Night's Dream*, and in the fairies that touched the imaginations of Ben Jonson, Herrick, Drayton, and even the youthful Milton, we find that the aerial and supernatural quality is the predominant feature in the characterisation. Altogether they are more romantic and interesting figures, and at the same time in their other-worldly conception are more real to the human imagination.

Comparatively modern fairy legends tell us how these little beings preside at the birth of man; and we know how at the birth of Ogier le Danois six fairies attend, five of whom give good gifts. In those parts of the world where there are mountains, mists, dangerous morasses, cataracts, and stormy oceans, all superstitions, being a belief in supernatural agencies, are naturally exaggerated, and, from the dangers to which the people are liable from the agencies they deem supernatural, the belief takes deep root in their minds. Accordingly, in flat and well-cultivated countries like England, the fairy superstition is simple and homely, connecting itself with matters of domestic routine, such as the sweeping of the dwelling-house, the skinning of the milk, the preservation of the butter, and the like, numerous allusions to which are found in Shakespeare. In Scandinavia and the Highlands the fairy people are connected with storms and convulsions, betray people to their death, fly away with them into the infinite cloud-land, or lead them through endless caverns within the earth. It has been observed as a further distinction that the fairies of the German or Teutonic tribes are more harsh, fierce, uncouth, or deformed than those of the Celtic nations, which have a tendency rather to the aerial and the graceful. Still the amount of common characteristics in the superstition throughout Europe is enormous. Its peculiarities have been found so much more emphatically displayed in Scandinavia than elsewhere as to have suggested the earlier and less philosophical view that modern fairydom is merely a remnant of the old mythology of the northern nations, communicated by them to a greater or less extent in all the countries over which their vikings carried their ravages.

There is a further distinction between the fairies of poetic and heroic literature and those of popular belief—the former being princes and princesses of chivalry, only distinguished from human beings by their superhuman superiority in all the qualities which elicited respect in the age of chivalry; while those of popular belief are small in stature, sometimes decrepit, and endowed with dispositions generally more allied to malignity than magnanimity. In Ireland and the Highlands they have been spoken of as a wandering remnant of the fallen angels, and in the west of England the pixies are the souls of infants who died before they were baptised. Sometimes they

are supposed to be human beings, metamorphosed or disembodied, and this form of the superstition has made fairyland a place of purgation for those whose sins have condemned them to it. The analogy is carried out in the belief that the services of the living can extricate the souls so situated; but it is rather through dexterity and courage than pure piety that the feat is achieved, and the rescues from fairyland form some of the most wild and exciting of the elfin narratives—as, for instance, the exquisite ballad of *Tamlane*. The only dark cloud that obscures the brightness of fairydom is the periodical necessity of paying a teind to hell—a necessity which casts unexpected light upon the radical affinities of the fairies, in spite of all the seeming gaiety and happiness of their world. Hence their desire for kidnapping human children, in order to pay with them the inevitable tribute. Again, they do not possess spiritual souls like men and women, and consequently have no immortality of existence—this notion forms the heart of the most exquisite of artistic fairy-tales, the *Undine* of Fouqué.

There is still another broad distinction into fairies that dwell in the upper air and fairies that dwell within the bowels of the earth, while a third class frequent the waters. The Scandinavians called the fairy inhabitants of the air white elves, those of the earth black. Whatever was genial, light, playful, and benevolent in the superstition clustered round the former; the latter did all the work that was dark, cruel, and rapacious. Naturally enough, the black or subterranean kind frequented mining districts, where they might be seen extracting the ore for themselves, and thus unwittingly leading the miner to rich veins of metal. They might be seen in an occasional peep through an aperture of a hill in their underground retreats, in chambers supported on jasper columns, where they were stowing away their ample stores of gold and silver. Some of the most exciting tales about the German *kobold*, and the Irish *leprechaun*, who was a creature of the same kind, are founded on the efforts of adventurous mortals to get possession of their riches. There exists a legend, occurring in nearly identical terms in several countries, which connects some piece of valuable plate belonging to a church with the underground fairies. The story of the horn of Oldenburg is a type of these narratives. Pictures represent it as a beautiful drinking-vessel, in the shape of a horn, exquisitely decorated with the finest fanciful silver-work, in the style contemporary with the richest Gothic architecture. The legend is that one day Otho of Oldenburg, being exhausted with hunting, and very thirsty, exclaimed, 'O God, would that I had a cool drink!' Thereupon there appeared before him, as if coming out of the rock, a lovely maiden, who offered him a drink in the fairy-horn. He made off with it, and saved himself from evil consequences by bestowing it on the church. Hence these relics are generally in churches; but one of them is still in the possession of an English family, and, as their prosperity was traditionally believed to depend on retaining it, it was called the 'Luck of Eden Hall.'

Puck and the pixies belong to the same class of beings. Of the elf-folks of Scandinavia, the male is old and ill-favoured, but the evil element in the elf-woman or elf-maid consists in her beauty, which renders her perilous to romantic and lovelorn youths, whom she beguiles either with her own charms or by assuming the aspect of their mistress. To our own literature belongs one beautiful story of this character—the ancient tale of the love between 'True Thomas' and the Queen of Fairyland, which the genius of some nameless maker has woven into imperishable verse. A common feature, both here

and elsewhere, in the stories of fairy-women who assume human form and give their love to men, is a restriction of some nature which must not be broken. All mermaids, lamias, and the like are subject to some such conditions. Thus, Melusine is once a week again a serpent from the waist downwards, and when her husband breaks her one condition and surprises her at her bath, she becomes a water-spite again.

In Ireland, and also in the Border country of Scotland, the fairy superstition has been incorporated into innumerable poetic legends and mystic traditions. T. Crofton Croker, in his *Fairy Legends and Traditions of the South of Ireland* (3 vols. 1828), presents a full and amusing account of the Irish fairies or elves, which he describes as 'a few inches high, airy, and almost transparent in body; so delicate in their form that a dew-drop, when they chance to dance on it, trembles indeed, but never breaks. Both sexes are of extraordinary beauty, and mortal beings cannot be compared with them.' They do not live alone, or in pairs, but always in large societies, and are governed by a queen. The same author adds: 'They are invisible to man, particularly in the daytime, and, as they can be present and hear what is said, the peasantry never speak of them but with caution and respect, terming them the good people, or friends. They have their dwellings in clefts of rocks, caves, and ancient tumuli. Every part within is decorated in the most splendid and magnificent manner; and the pleasing music which sometimes issues from thence in the night has delighted those who have been so fortunate as to hear it.' There are Irish fairies, however, of more special character. Among these are the *banshee*, or female spirit who watches a particular family; the *leprechaun* or *cluricaun*, an elf of evil disposition, who usually appears as a wrinkled old man, and has a knowledge of hidden treasure; and the *pooka*, a spirit of diabolical disposition, who sometimes appearing as an eagle or a black horse hurries the person he gets possession of to destruction. Of similar varieties are the Scottish elves: the *brownie*, or domestic spirit nearly corresponding to the Banshee; and the *kelpie*, a kind of water-horse, not unlike the Pooka, and in form somewhat analogous to the being sung by Leyden in his charming ballad, 'The Court of Keeldar' (*Minstrelsy of the Scottish Border*):

'Brown dwarf, that o'er the murland strays,
Thy name to Keeldar tell.'
'The Brown Man of the murs, who stays
Beneath the heather-bell.'

Fairies cannot be seen by mortal eyes with impunity—it is the main part of Falstaff's terror when he sees his assailants: 'They are fairies; he that speaks to them shall die' (*Merry Wives*, V. v.). But the greatest risk that mortals run from the denizens of fairyland is that already alluded to, of having their children stolen from the cradle, and a changeling substituted who bears a resemblance to the stolen infant, but is an ugly little creature and never thrives. On this theft of a maid, who is carried to fairyland, but in the course of time returns to her parents, James Hogg founded his fine ballad of 'Kilmeny' (*Queen's Wake*).

Besides being embalmed in imaginative literature, the fairy has a perpetual memorial in the small, exquisitely shaped arrow-heads found so abundantly in northern countries, where they were long known as elf-arrows, or bolts with which the more malignant fairies sometimes slew or injured cattle and human beings; thus, when a poor man's cow or heifer was suddenly affected with some deadly and incomprehensible illness, it was said to be 'elf-shot.'

Fairy Tales (1831); Halliwell's *Fairy Mythology of A Midsummer Night's Dream* (1845); Schreiber, *Die Feen in Europa* (1842); Maury, *Les Fées du Moyen Âge* (1843); Grimm's *Deutsche Mythologie* (1835; trans. 1879-88); Wirt Sikes, *British Goblins* (1879); Hartland, *Science of Fairy Tales* (1891); Evans Wentz, *The Fairy Faith in Celtic Countries* (1912); Floris Delattre, *English Fairy Poetry* (1912); also the collections of fairy tales of Grimm, Crofton Croker, Von Hahn, J. F. Campbell, Dasent, Ralston, &c.

Fair Isle, a solitary Shetland island, 24 miles SSW. of Sumburgh Head. It is 3 miles long by 2 broad, and 3 sq. m. in area, with high rocky cliffs and promontories, rising in the Sheep Craig to a height of 480 feet. The men are fishers; the women knit. At Stromceiler Creek was wrecked, in 1588, a ship of the Spanish Armada, commanded by Don Juan López de Medina. He escaped with a few of his crew; and from these shipwrecked Spaniards the natives of Fair Isle are said to have acquired their art of knitting parti-coloured woollen articles.

Fairs (Fr. *foire*, from Lat. *feriae*, 'holidays'), great periodical markets, some of which are chiefly devoted to one kind of merchandise, while others, of a wider scope, afford opportunity for most of the sales and purchases of a district. Fairs have long been regularly held in most parts of Europe and in many parts of Asia; but, as they belong rather to a state of things which is passing away than to modern civilisation, they have not been established or have not acquired the same importance in America. In Italy, towards the close of the 5th century, we first find authentic accounts of fairs specially designed as marts for commerce, and in Greece it has been suggested that at the celebrated Greek games trade was no entirely subordinate object. Thus, Cicero tells us that as early as the age of Pythagoras large numbers of people attended the religious games for the purpose of trading; and we know how at Delphi and other places a fair was held almost every year. In modern Europe they appear to have been associated with the church festivals, which were found to afford convenient opportunities for commercial transactions, the concourse of people being such as took place upon no other occasion. This origin of fairs is commemorated in their German name *Messe*—i.e. 'mass' (compare the *-mas*, for 'mass', in such words as Lammass, Martinmas, &c.) Some festivals, from circumstances of place and season, speedily acquired a much greater commercial importance than others, and began, therefore, to be frequented by buyers and sellers even from remote parts of the world. When the ordinary means of communication between countries and opportunities for the exchange of commodities were very limited, fairs were of great use. Princes and the magistrates of free cities found it to their advantage to encourage them, and many privileges were granted, which in some places still survive. Courts of summary jurisdiction—commonly called in English 'pie-powder' (Fr. *pieu poudré*), from the dusty feet of the suitors—were established distinct from the ordinary courts of the county or city, for the determination of questions which might arise during the fair. In connection with all this the practice was necessarily adopted of publicly proclaiming the commencement and duration of the fair, and this still subsists where scarcely any other vestige remains of the old privileges of fairs.

In western Europe the goods exposed for sale at fairs are chiefly those in respect of which there is a frequent change of fashion. While in some parts of the Continent persons of all ranks still wait (or did lately) for the great yearly fairs to make their principal purchases of clothing and of manufactured articles of all kinds, such things as corn,

wine, spirits, tea, coffee, sugar, tobacco, oil, &c. are seldom seen in them. It is otherwise, however, in places on the outskirts of civilisation; and almost all the produce of great provinces is sold, and all that their inhabitants require is bought, at such fairs as those of Kiakhta and Nijni-Novgorod. In France much of the European commerce of the middle ages was transacted at the famous fairs of Champagne and Brie, where the merchants of Italy, Spain, and France congregated. The British fairs really of much use at the present day are those at which horses and live-stock are exposed for sale, and even these have greatly decayed in importance: of these some held on the borders of the Scottish Highlands and elsewhere in Scotland were wont to be frequented by buyers and sellers from all parts of the kingdom. Such are the fairs or trysts, as they are called, at Falkirk, Doune, &c. At other great yearly fairs in the south of Scotland lambs are sold; and fairs chiefly for the sale of the annual produce of pastoral districts are common in almost all parts of the world.

Of the three annual fairs at Leipzig the most important are the Easter and Michaelmas fairs, each of which lasts three weeks. The chief articles sold are leather, cloth, and furs. The Leipzig Book-fair is a fair in name only, being really an occasion for the settlement of accounts among booksellers and publishers; it occurs at the time of the Easter fair. Next to the Leipzig fairs those of Frankfort-on-the-Main are the most important in Germany. The great fairs of Lyons and Beaucaire in France, of Frankfort-on-the-Main and Frankfort-on-the-Oder in Germany, of Budapest and Debreczen in Hungary, of Sinigaglia, Alessandria, and Bergamo in Italy, and of Nijni-Novgorod (q.v.) in Russia are, or were, among the most important in Europe; the last, which attracted representatives from all parts of Russia, occupying a site comprising 7 sq. miles. The fairs of Tanta in Lower Egypt, of Kiakhta and Irbit in Siberia, of Mecca in Arabia, and of Hurdwar in Western India are also of very great importance. That of Kiakhta is a sort of barter-market, where formerly almost all the commercial transactions between Russia and China took place. The fairs in Britain have latterly sunk for the most part to insignificance, and in many instances have entirely disappeared. They were gatherings adapted to a comparatively backward state of society, when the provincial stores of goods were few, and the means of communication defective. The prevalence of good roads, populous towns with dealers in miscellaneous wares, and improved methods of transport have superseded the necessity for the ordinary class of fairs, and in consequence they have in some cases degenerated into mere scenes of merriment. Such were Bartholomew Fair (q.v.), Greenwich Fair, Glasgow Fair, and Donnybrook Fair, near Dublin; all either extinct or nearly so. The boisterous merriments at these fairs were of old the devices employed as likely to attract a great concourse of people; hence each fair had its sport or drollery—football, wrestling, yawning, cudgel-playing, throwing at cocks, sack-races, flying dragons, grinning through horse-collars, mock-giants, monstrous fishes, soaped pigs, smoking-matches, eating hot hasty-pudding, whistling, wheelbarrow races. At Stourbridge Fair, one of the most important in the kingdom, an excellent proclamation was issued in 1548 by the university of Cambridge in 'crying the fair,' containing among other 'comaunds' this clause: 'No brewer sell into the fayer . . . a barrill of good ale above tuo shillings—no long ale, no red ale, no sopye ale, but good and halsome for man's body, under ye payne of forfeiture.' It has been remarked that fairs were

established for the most part on the frontiers of the kingdom, or on the marches of ancient provinces; or at the foot of high mountains, at the beginning or end of the snow-season, which for months shuts up the inhabitants in their valleys; or in the neighbourhood of famous cathedrals or churches frequented by flocks of pilgrims; or in the middle of rich pastures. A fair at Christ's Kirk, in Aberdeenshire, held in May, when the nights are very short, began at sunset, and ended an hour after sunrise: it was called 'Sleepy Market.' In America the word fair is used rather for what would in England be called an industrial exhibition, bazaar, or 'fancy fair.' See Cornelius Walford's *Fairs, Past and Present* (1883).

Fair Trade. See FREE TRADE, PROTECTION.

Fairy Rings are spots or circles in pastures, which are either more bare than the rest of the field, or more green and luxuriant. Frequently a bare ring appears, like a footpath, with green grass in the centre, and the circle which the ring forms, or of which it might form a part, is often some yards in diameter. Apart from supernatural hypotheses, it was sometimes imagined that they might be the effect of lightning. Dr Witheing appears to have been the first, in 1796, to ascribe them to the growth of fungi; and they are now known to be due to the outwardly spreading growth of the perennial subterranean mycelium of various fungi, chiefly species of *Agaricus*, even the Common Mushroom (*A. campestris*) showing a tendency to grow in the same manner. The spot where the agaric has already grown is unfitted for its continued nourishment, and the mycelium (spawn) extends outwards to new soil, the fungus exhausting the soil to which it extends for the immediate nourishment of grass, but enriching it afterwards by the highly stimulating products of its own decay. Fairy rings of large size sometimes occupy the same situation for many years. The circle is almost always imperfect, some accidental obstacle having broken the completeness of the expanding ring of mycelium.

Faisal, king of Iraq, was born at Taif in 1885, a younger son of Husein, afterwards king of the Hejaz. In his youth he lived in Constantinople, took part in the revolutionary movement, and returned with his father to Mecca in 1908. He served against the Idrisi, and sat in the Turkish parliament, but in 1915 became a leader in the Arab nationalist movement. In the Great War he organised rebellion, and with an army accompanied the British to Damascus, where he set up an administration. He attended the Peace Conference, and in 1920 was proclaimed king of Syria by the National Congress, but the French expelled him by force of arms. Next year, recommended by Britain, he was elected king of Iraq.

Faith is used by theologians in various senses. It is sometimes taken to denote the mere assent of the understanding to a set of facts or of propositions set before it; but it is more peculiarly used to express the living reception by the heart of the 'truth as it is in Christ.' Some divines have enumerated no fewer than four kinds of faith: (1) The faith of miracles, or that immediate persuasion of the almighty presence and power of their Master, which enabled the early Christians to work miracles—a persuasion, apparently, which might exist and issue in astonishing results without being associated with moral excellence. 'Though I have all faith,' says St Paul, 'so that I could remove mountains, and have not charity, I am nothing.' (2) Historical faith, or the assent of the understanding to truth, the evidence of which is irresistible, such as we have described above. (3) Partial or temporary faith, such as our

Lord implies in his exposition of the parable of the Sower, and as appeared to animate those who, after having followed after Christ, turned back and walked no more with him; and (4) Saving faith, or the persuasion of Christian truth wrought in the heart by the Holy Spirit.

These distinctions are rather theological refinements than anything else; the proper and characteristic meaning of the term faith in Scripture has little to do with any of them except the last. 'Faith,' says the writer of the Epistle to the Hebrews, 'is the substance of things hoped for, the evidence of things not seen.' It is a vision, quality, or capacity of soul whereby spiritual truth is apprehended, and spiritual life engendered. The distant is brought near by it, and substantially appropriated; the unseen is felt to be a reality. Faith is the organ by which the soul passes beyond the present and the visible to the eternal and the invisible. Still more characteristically, perhaps, faith is the living affection which binds the Christian to Christ as a Saviour.

Faith, in the distinctively Christian sense, can only exist by the operation of God's Holy Spirit. 'For by grace are ye saved, through faith; and that not of yourselves; it is the gift of God.' Orthodox divines greatly insist on the necessity of this operation of the Spirit of God, yet not so as to exclude the active co-operation of man. The Pelagian and Antinomian extremes respectively throw out—the former the divine, the latter the human element. Orthodoxy combines the two, attributing to God the effective agency, but to man a real and voluntary concurrence. For the theological controversies connected with faith, reference must be made to the theological treatises of the different communions.

Faithfull, EMILY (1835–95), born at Headley Rectory, Surrey, early became interested in the condition of working-women, and in 1860 founded in London a printing establishment where women were employed as compositors. She was appointed printer and publisher in ordinary to the queen. In 1863 she started the *Victoria Magazine*, in which the claims of women to remunerative employment were set forth; and in 1868 she published *Change upon Change*, a novel.

Faith-healing, a system of belief based on James, v. 15, that sickness may be treated without any medical advice or appliances, if the prayer of Christians be accompanied in the sufferer by true faith. Dorothea Trudel, at Maunendorf in Switzerland, is said to have wrought marvellous cures by faith and prayer alone between 1850 and 1860. Pastor Blumhardt began a similar system of cure at Möttlingen, in Württemberg. He ultimately resigned his charge, and bought a property with a sulphurous mineral spring at Boll, near Göppingen, where his system was fully developed in a large and much-frequented building specially arranged for his patients. He died in 1880, aged seventy-five. See his *Life* by Zündel (2d ed. Zurich, 1881). There are homes for faith-healing, called *Bethshan* (Heb., 'house of rest'), at various places in Britain and the United States. Some diversity obtains amongst believers whether the cures are to be accounted miraculous or not, and whether, in addition to the laying on of hands, anointing with oil should be practised. A committee of physicians and clergymen was, in 1914, of opinion that the physical results of what is called 'Faith' or 'Spiritual' healing do not prove on investigation to be different from those of mental healing or healing by 'suggestion.' See PECULIAR PEOPLE, CHRISTIAN SCIENCE.

Faithorne, WILLIAM (1616–91), English engraver. See ENGRAVING.

Faizabad, the capital of the Afghan dependency of Badakhshan (q.v.), stands on the Kokcha, a tributary of the Amu-Daria, 180 miles NE. of Kabul. It is noted for the rubies found near it.—For the Indian town of this name, see FYZABAD.

Faizpur, a town of Bombay Presidency, about 200 miles E. of Surat, with a reputation for its dark-blue and red dyes and cotton prints; pop. 7000.

Fakir, an Arabic word meaning 'indigent' (not to be confused with *fakih*, vulgarly pronounced *filh*, 'a pedagogue'), and commonly used to designate a member of an order of mendicants or penitents, chiefly in India, and the neighbouring countries. In Persia and Turkey the word is also synonymous with Dervish (q.v.), and in Egypt is particularly assigned to that class of dervishes which performs *sitrs* and chants funeral dirges. The origin of Fakrism, an institution which reaches back to the most remote antiquity, is lost in mythical darkness. The common account of the son of a mighty raja, who, expelled from his home and country by the cruelty of his father, made a vow, half in revenge and half in contrition, henceforth to roam a beggar through the world, and to win proselytes to a life of poverty and self-mortification, as most befitting man and most pleasing to the Deity, can hardly be called historical. The same yearning for rest, for peace and pious contemplation, for escape from the noise and turbulence of the world, has everywhere and always led pensive minds into retirement and solitude; and constant seclusion and ceaseless meditation in India, as elsewhere, produced in all but exceptional minds their sad results. Thus abstinence became mortification and self-torture; mental repose was turned to mystic self-absorption or frenzied exaltation. This leaning of the Hindus to a life of asceticism was fostered by their religion, which enjoins various exercises of penance and mortification upon the three higher castes in general, but upon the Brahmins in particular. The world and its usages have no more any claim upon them; even religious ceremonies are no longer necessary to the 'United with God.' They go naked, or in filthy rags, receive the mearest food only, and that without either demand or thanks. Their ethical code consists in the observance of truth, chastity, internal purity, constant repentance, and contemplation of Deity. Fakrism seems chiefly to have been framed upon this phase of Brahminism, and its adherents were not only pious men, but occasionally saints, believed to be workers of 'miracles' and healers of all ills, especially epilepsy and sterility. But the halo which from the first surrounded Fakrism, and the ready homage offered by the people, attracted to its ranks at a very early date many whose motives were anything but pure, and who under a garb of humility and mendicancy collected fabulous treasures. Strabo already distinguishes these vagabonds from the more honest members of their class, and, if we may trust the travellers of our own day, the more respectable element has now altogether disappeared. Their number is variously stated. In the time of Tavernier's visits (1643-69) there were more than 1,200,000 Hindu and 800,000 Mohammedan fakirs in the East Indies, and a modern estimate is something over 3,000,000. At times, especially on their return from distant pilgrimages, they are even dangerous, as the killing of an unbeliever is supposed to be an infallible introduction to the glories of paradise. They either live separately as hermits or solitary mendicants, or unite in large gangs, carrying arms and a banner, beating drums, and sounding horns as they approach a town or village. Their appearance is often disgusting in the extreme; they go naked, besmeared with the dung of the holy animal, the cow. Some bedeck themselves with the

skins of serpents, some with human bones; others array themselves in the garb of women. Their fearful shrieks, and the rollings of their eyes, add to the hideousness of their appearance. Imitating madmen, they generally end by becoming madmen. Some pass their whole lives in iron cages, laden with heavy chains; some clench their fists till their nails grow through the hand; others hold aloft both their arms till they become like withered branches; while others, again, tie their hands and feet together, and roll head over heels for long distances—for thousands of miles in some cases, it is said. Some forms of Christian Asceticism (q.v.) have produced types, such as Simeon Stylites (q.v.), worthy to be compared with Mohammedan fakirs.

Falaise, a town in the French department of Calvados, on the Ante, a feeder of the Dives, 23 miles (by rail 31) SSE of Caen. Crowning a rocky platform, with a steep cliff or *falaise*, stands the noble ruined castle once the seat of the dukes of Normandy, and the birthplace of William the Conqueror. Its keep is Norman, whilst 'Talbot's' Tower is said to have been built by Talbot, after the capture of Falaise by Henry V. of England. The town has cotton works and tanneries. At the suburb of Guibray a fair, established by the Conqueror, is held in August. Pop. 6000.

Falashas. See ABYSSINIA.

Falb, RUDOLF, weather prophet, born 13th April 1838 at Obdach in Styria, was trained a priest, but devoted himself to science, especially meteorology, and after extensive travels settled in Berlin. He held that earthquakes, storms, heavy rainfalls, and other terrestrial phenomena took place on 'critical days,' brought about by the conjoint attraction and influence of sun and moon on the atmosphere and the fluid interior of the earth—a view rejected by most meteorologists—and could therefore be calculated beforehand. He wrote many works on astronomy, physiography, and meteorology, and till his death in 1903, issued half-yearly prognostications of the weather.

Falcón, a maritime state of Venezuela (q.v.), on both sides of the Gulf of Maracaybo. The chief towns are Maracaybo and Coro. Pop. 128,000

Falcon (*Falco*), the crowning genus in the family Falconidæ, including numerous species which excel even the eagles as birds of prey. They are represented in all parts of the world except the South Sea Islands, and are almost always distinguished by their carnivorous habit, active life, and that evolved hunting talent which has led to the frequent use of not a few forms in the sport of Falconry (q.v.). The beak is short and strong, with a sharp-hooked point and an upper tooth fitting into a depression in the lower half; the claws are strong and sharp, and the outer toe is rather longer than the inner; the lower part of the leg is covered with a net-like pattern of scales; the regions round about the keen eyes are bare; the wings are long and pointed; the tail is also long and rounded. The falcons are pre-eminent for boldness, keen sight, and muscular power. One is said to have traversed the distance between Fontainebleau and Malta, not less than 1350 miles, in 24 hours; and the speed attained when in pursuit of prey has been estimated at 150 miles an hour. They are able to soar to an immense height, and always endeavour to get above the bird they wish to strike. The distinctness of the various falcons is much disputed by experts; the fivefold grouping here followed is that adopted by Professor A. Newton.

(1) The cosmopolitan Peregrine Falcon (*F. peregrinus* or *communis*) was formerly a firmly established British species, but, though still persisting in some parts, has suffered enormously from unreason-

able persecution. It is a powerful bird, though only about 16 inches long, and is brave and masterly in its hunting. In colour the adult is blackish-brown to grayish-blue above, and whitish, with a reddish shade, beneath. Especially on the lighter under surface are seen the dark bars, which in this and the gyrfalcons are longitudinal before and transverse after the first moult. The female is larger and more powerful than the male, with a slightly longer body, and decidedly longer wings; she is the 'falcon' of the falconers, the male is a 'tiercel,' the more rufous young forms are 'red falcons' or 'red tiercels.' The peregrine preys upon flying birds, such as wood-pigeons, all sorts of grouse, partridges, and plovers, or by the seashore on puffins, auks, and other marine birds. The falconers pit them against herons, and on its own account a falcon has been known to attack an intruding eagle. The cogent argument used against exterminators of falcons is that which may be urged against any disturbance of the balance of nature; that they kill grouse, pheasants, and other game-birds is undoubted, but they naturally tend to weed out the weaker forms, and thus, unless they predominate unduly, do more good than harm. Some even regard the grouse disease as a nemesis of the destruction of the nobler falcons. Peregrines usually live in pairs, and build large nests, generally of sticks and herbage, on very varying sites—sea-cliffs, inland rocks, or even trees. The Australian Peregrine (*F. melanogenys*) and the North American form (*F. anatum*) are probably only

varieties of the above species.

(2) Next come a number of northern gyr- or jer-falcons, like the preceding, formerly much used in falconry. The Scandinavian Gyrfalcon (*F. gyrfalco*), which sometimes wanders farther south, and has been seen wild in Britain; the Icelfalcon (*F. islandicus*), which also comes to Britain; the nearly pure white Greenland Falcon (*F. candicans*), of

Greenland Falcon (*Falco candicans*), which the migrating young have been seen in Britain; and the North American Gyrfalcon (*F. labradorus*) are important forms. In their native haunts they feed on ptarmigan, geese, and other such birds.

(3) Somewhat distinct are the desert falcons, by some authorities distinguished as the 'lanners' (*F. lannarius*) and 'sakers' (*F. sacer*) of south-eastern Europe, North Africa, and south-western Asia, both used in falconry.

(4) The Merlin (*F. aesalon*) is a British species, like the peregrine in process of extermination. The male is bluish above and rather ruddy beneath. It is decidedly smaller than the peregrine, and preys upon smaller birds, such as finches, larks, and thrushes; yet so bold is it that it has been known to turn threateningly upon man.

(5) The English Hobby (*F. subbuteo*), with upright carriage and long wings, is a summer visitor in Britain, an eager enemy of larks, and sometimes even condescending to eat insects. Both of the last species have been used in British falconry. The

Kestrel (*Tinnunculus*) is a nearly allied genus, separately discussed.

Falcone, ANIELLO, Italian battle-painter, born at Naples in 1600. He studied under Ribera (Lo Spagnoletto), and subsequently founded a school of painters at Naples. During Masaniello's outbreak (1647) he organised his scholars and dependents into a secret band (Compagnia della Morte) for assassinating Spaniards at night. On the suppression of the insurrection Falcone betook himself to France, but subsequently returned to Naples, where he died in 1665. His works, few in number, represent chiefly military scenes.

Falconer, HUGH, an eminent botanist and palæontologist, was born at Forres in Elginshire, 29th February 1808. He graduated M.A. at Aberdeen in 1826, and M.D. at Edinburgh in 1829, and joined the medical service in Bengal of the East India Company. Appointed in 1832 keeper of the botanic garden at Sahāranpur, he distinguished himself by the discovery of a large number of fossils in the tertiary deposits of the Siwālik hills. It was under his care that the first experiments were made by government in the growth of tea in India; and it was he who discovered during a journey in Kashmir the asafetida plant of commerce. Overwork told upon his health, and in 1842 he had to return to England, whither he carried five tons of fossil bones and seventy large chests of dried plants. In England Falconer devoted himself to writing memoirs and papers on Indian botany and palæontology, to arranging the Indian fossils in the British Museum and East India House, and to preparing his great illustrated folio, *Fauna Antiqua Sivalensis* (parts i.-ix. 1846-49). He returned to India in 1847 to become superintendent of the botanic garden and professor of Botany in the Medical College at Calcutta. He came home finally in 1855, and in spite of failing health continued his palæontological studies with heroic energy. He died in London, 31st July 1865. A fund of £2000 was raised to provide a memorial of this devoted martyr to science. A memorial fellowship was also founded at Edinburgh University to promote the study of palæontology and geology. The *Palæontological Memoirs and Notes of the late Hugh Falconer* were published in 1868.

Falconer, WILLIAM, poet, was born in Edinburgh on 11th February 1732. A barber's son, he went early to sea, and before he was eighteen years of age was shipwrecked off Cape Colonna in Greece. The incidents of this voyage and its disastrous end form the subject of Falconer's principal work, the poem entitled *The Shipwreck* (1762). He then entered the royal navy, being appointed towards the end of 1769 purser on the *Aurora* frigate, which foundered at sea, with all hands, shortly after 27th December, the day on which she left Capetown. Falconer wrote several poems, but *The Shipwreck* is the one on which his fame rests; it went through three editions during its author's lifetime. His *Demagogue* is a satire on Wilkes and Churchill (1764), and he was also author of the *Universal Marine Dictionary* (1769).

Falconet, a name used in the 15th and 16th centuries for a small field-gun. The ball weighed from 1 to 2 lb., and the gun from 5 to 15 cwt.

Falconidæ, a large family of Birds of Prey (q.v.), occupying a position similar to that of Felidæ among carnivores. The muscular strength and power of flight; the habit of preying upon living animals, and that in daylight; the world-wide representation by over 300 species, are to be noted. The beak is rather short, but very strong, and highest at the root; the partition between the nostrils is complete; the upper margin of the eye-

socket projects; the feet bear strong, sharp, rending claws and large sole-pads. The family includes the Falcons *par excellence*—e.g. the genus Falco; the Eagles—e.g. Aquila, Haliaeetus; the Buz-

zards—e.g. Buteo; the Kites—e.g. Milvus, Elanus; the Hawks—e.g. Nisus, Astur; the Harriers—e.g. Circus; the Caracaras—e.g. Ibycter, Polyborus—for which see the separate articles.

Falconry (from Old Fr. *faulconnerie*), the art of training falcons and hawks to the chase. The term hawking (from M.E. *hawk*, O.E. *hafoc*), though often used synonymously, is more

Head and Foot of Brazilian Eagle.
